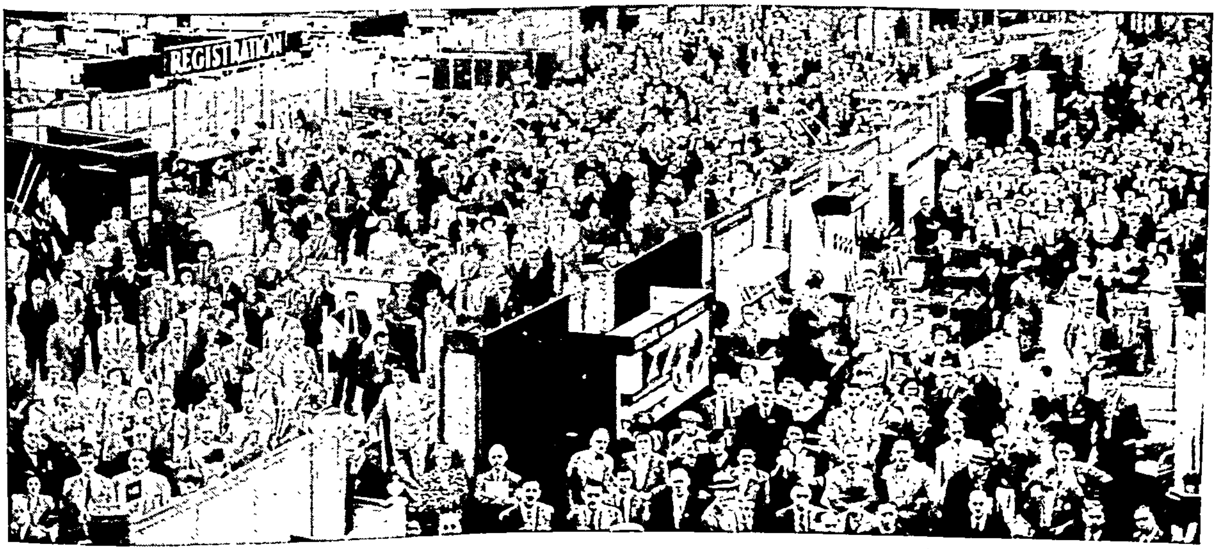
The exhibits will be open daily from 8:30 A.M. to 6:00 P.M. each day beginning Monday, June, 21 and closing noon, Friday, June 25. These hours together with the close proximity to the scientific exhibits will make it unusually convenient to add to your well of knowledge and expand your resevoir of information...for indeed, the Technical Exposition will be a most stimulative and educational feature; and, capable, highly trained attendents will be on hand to bring these exhibits to life and make them a dramatic summary of results achieved by the cooperation of medical industry with medical science.

Following are brief descriptions of some of the exhibits to aid you in knowing in advance which displays most intimately relate to your problems. You are cordially urged to spend as much time as possible visiting the Technical Exhibition.

Thos. R. Gardiner,

Business Manager and Director of Technical Exhibits



LIST OF TECHNICAL EXHIBITORS WITH DESCRIPTIVE ITEMS RECEIVED UP TO PRESS TIME

ABBOTT LABORATORIES

Booths A-74, A-76, B-75, B-77

"The Sneezing Man," an ingenious mechanism dramatizing the trials of an allergy victim, will highlight an unusual exhibit by Abbott Laboratories on an antihistaminic drug. Other Abbott products to be featured are Pentothal Sodium, a brief-acting barbiturate for intravenous use; and Tridione, a drug for the control of the petit mal triad and other convulsive seizures.

AHLSTROM SURGICAL COMPANY

Booth C-134

The Ahlstrom Surgical Company—a new exhibitor—will feature a selected line of fine surgical instruments, hospital supplies and physicians' supplies. The display will include various instruments for E.E.N.T., Neurological, Plastic, and General Surgery.

W.D. ALLISON COMPANY

Booth A-84

A new and wonderful surprise awaits you at the Allison exhibit this year. You won't want to miss it!

ALMAY, INC.

Booth C-79

An attractive display of hypo-allergenic cosmetics may be inspected in the Almay exhibit. A feature of this exhibit will be Almay Hypo-Allergenic Nail Polish. Specific information and descriptive literature on these scientifically formulated cosmetics will be made available to all physicians by members of the Almay staff.

A. S. ALOE COMPANY

Booths C-173, C-175

AMERICAN CAN COMPANY

Booth B-129

AMERICAN CYSTOSCOPE MAKERS, INC.

Booth B- 115

Among the attractions at the American Cystoscope Makers, Inc. booth, will be new telescopic bronchoscopes, gastroscopes, and other telescopic diagnostic instruments; catheters; and electrosurgical equipment.

AMERICAN HOSPITAL SUPPLY CORPORATION

Booths A-8, A-10

The American Hospital Supply Corporation will exhibit a full range of Baxter Parenteral Products—Intravenous Solutions, including the Blood Transfusion and plasma equipment plus disposable accessories for the administration there of; Blood grouping Serums that excel in accuracy, speed and dependability; and certain selected Tomac products that simplify, if not solve many hospital problems.

AMERICAN OPTICAL COMPANY

Booths A-142, A-144, A-146, A-148

AMERICAN PHYSICIANS ART ASSOCIATION

Adjacent to Scientific Exhibits

Here you will see an unprecedented ART SHOW of outstanding works by members of the American Physicians Art Association--and don't forget to vote for your idea of the best art object at this Exhibition. The winning doctor will be awarded the truly handsome permanent "Popularity Trophy" --on display at the Art Show.

AMERICAN SEAL-KAP CORPORATION

Booth B-96

AMERICAN STERILIZER COMPANY

Booths B-157, B-159

AMES COMPANY, INC.

Booths B-34, B-36

Decholin, the standard hydrocholeretic agent for the treatment of biliary tract diseases, will occupy a prominent place in the Ames exhibit. Another interesting feature will be a demonstration of Clinitest and Hematest—simplified tests for the detection of urine-sugar and occult blood.

ANSCO

Booth A-164

Outstanding radiographs made with both screen and non-screen techniques will be exhibited here. An unusual and interesting display of Ansco Color transparencies will show the natural and true color recording of the original subject. Don't fail to test your "color sense" (visibility and appreciation of color) with a series of special Ansco Color transparencies.

APPLETON-CENTURY-CROFTS, INC.

Booth C-36

Of particular interest in the Appleton-Century-Crofts exhibit are the new 9th (1948) Edition of Zinsser & Bayne-Jones, TEXTBOOK OF BACTERIOLOGY under new authorship; the new 2nd (1948) Edition of Maingot, ABDOMINAL OPERATIONS; W. Wallace Morrison's DISEASES OF THE EAR, NOSE AND THROAT; the new 5th (1948) Edition of Cole & Elman's GENERAL SURGERY; and advance information on many other important titles and revisions which are in preparation.

ARMOUR AND COMPANY

Booth B-31

For their initial exhibit at a general session, Armour Toiletries, a division of Armour and Company, is presenting Stork Baby Products. These products consist of the famous Stork Castile Soap, for 40 years a leader in baby's complexion care, and the scientifically prepared Stork Baby Oil and Stork Baby Powder. All three of these products are accepted for advertising in A.M.A. publications.

THE ARMOUR LABORATORIES

Booths A-168, A-170, A-172

The Armour Laboratories, *a pioneer in the* field of Endocrinology, will welcome members of the American Medical Association at the Armour exhibit in booths A-168, A-170, A-172. If you have not received copies of Armour booklets on THE THYROID GLAND, FUNCTION AND MALFUNCTION OF THE BILIARY SYSTEM, and ARMOUR ATLAS OF HEMATOLOGY, you may secure them at the Armour booths.

THE GORDON ARMSTRONG COMPANY, INC.

Booth B-32

The Armstrong X-4 Baby Incubator -- tested and approved by Underwriters' Laboratories for use with oxygen - may be seen here. It supplies heat, humidity, and oxygen for the physician to use in the treatment of premature or any sick or debilitated baby. An emergency service has been established for rush shipments by Air Express to all parts of the world.

AYERST, MC KENNA & HARRISON, LIMITED

Booths C-57, C-59

The potency of "Premarin," its convenience *of administration and flexibility of dosage, will* be summarized in the Ayerst, McKenna & Harrison booth. "Premarin (Estrogenic Substances—water-soluble) is a highly effective and well tolerated preparation of naturally occurring, orally-active, conjugated estrogens (equine). The potency of "Premarin" is expressed in terms of its principal estrogen, sodium estrone sulfate.

C. R. BARD, INC.

Booth B-27

BARNETT OPTICAL LABORATORIES

Booth C-46

BARRY LABORATORIES, INC.

Booth A-111

BAUER & BLACK

Booths C-85, C-87

W. A. BAUM CO. INC.

Booths C-101, C-103

All models of the Lifetime Baumanometer will be displayed and demonstrated for the doctors in attendance. Those who maintain a central examining place will be especially interested in investigating the WALL Model Baumanometer. In addition, a full line of accessories - including special infant and child size bloodpressure cuffs will be available at the Baum exhibit.

BAUSCH & LOMB OPTICAL CO.

Booths A-40, A-42

A number of important new scientific instruments for research, diagnosis and refraction will be on display at the Bausch & Lomb *exhibit. Included* will be the "L" Camera, for photomicrography; the "E" research microscope with low position, find adjustments; Flourescence accessories for quick, positive T.B. diagnosis; Phase contrast accessories for examining unstained specimens; and the Allen Gonioscope Prisim for exploration of the anterior chamber angle of the eye.

BAYBANK PHARMACEUTICALS, INC.

Booth A-70

BECK-LEE CORPORATION

Booth B-80

BECTON, DICKINSON & COMPANY

Booths C-141, C-143

BEECH-NUT PACKING COMPANY

Booth A-173

Nutritionists in attendance at the Beech-Nut exhibits will be glad to answer any questions regarding the thirty-seven varieties of Beech-Nut strained and junior foods. They will also be happy to describe their Nutrition Program and will have on hand the charts which they use to teach mothers in various "well-baby" clinics.

BELTONE HEARING AID COMPANY

Booth C-178

In addition to a demonstration of special fitting procedure, showing how Beltone Hearing Aids can be "automatically" fitted to all types and degrees of hearing loss by the use of the Selectometer, the Beltone display will show the new Symphonette model, with the "dime size" M-2 receiver, which delivers 2 to 6 times more sound intensity than previous models.

CHARLES BESELER COMPANY

Booth C-62

THE BEST FOODS, INC.

Booths B-100, B-102

A visit to the Best Foods exhibit will clearly show you the nutritional value of Nucoa, the wholesome nutritious vegetable margarine, which contains 15,000 units of Vitamin A to the pound. Also of interest will be the famous Best Foods Hellmann's Real Mayonnaise and the other Best Foods Products. Miss Elsie Stark, Director of Consumer Education, who will be in charge of the booth, will welcome questions about the products.

THE BILHUBER-KNOLL CORP.

Booths B-145, B-147

The Bilhuber-Knoll Corporation will present Dilaudid, Metrazol, Theocalcin, and other "Council-Accepted" medicinal chemicals that have established their place in the physician's individualized prescriptions. Your visit to booths B-145 and B-147 and your discussions of these prescription chemicals will be welcomed.

J. BISHOP & CO. PLATINUM WORKS

Booths A-51, A-53

The Bishop exhibit will feature Bishop Blue Label hypodermic needles, the Albalon needle, the first hypodermic needle with a plastic hub, and other newly developed specialized needles for special work. The latest improvements in hypodermic medication methods will also be presented by a specially trained group of representatives.

THE BLAKISTON COMPANY

Booth C-20

The Blakiston Company will have an attractive exhibit of new and standard books. In addition, there will be advance information on forthcoming titles of importance to the profession. A number of new titles have been added to the Blakiston Recent Advances Series. Ask to see: Ricci DIAGNOSIS IN GYNAECOLOGY; Smith and Gault ESSENTIALS OF PATHOLOGY; Stitt, Clough and Branham PRACTICAL BACTERIOLOGY, 10th Edition; Lillie *HISTOPATHOLOGIC* TECHNIC; Epstein STRABISMUS; Fishbein MEDICAL WRITING.

THE BOOK SHOP BINDERY

Booth C-22

The atmosphere of a pleasant, attractively arranged reception room will greet visitors to the Book Shop Bindery exhibit. Among the authentic appointments *of this inviting* room will be several shelves of standard medical journals in the distinctive gold-stamped binding designed by the *Book Shop Bindery and authorized* by the publishers. Visitng physicians are invited to inspect the volumes *and to make* any inquiries they wish about the materials and workmanship, the convenience, practicality, economy and background value of adopting authorized book bindings for their own reception rooms.

BORCHERDT MALT EXTRACT COMPANY

Booth B-169

THE BORDEN COMPANY

Booths C-31, C-33, C-35, C-37

THE GEORGE W. BORG CORP. (GIBBS DIVISION)

Booths B-144, B-146, B-148, B-150

A feature of the George W. Borg Corporation's exhibit on x-ray equipment will be the Deep Therapy Machine utilizing high frequency which makes it *possible to have a very small* transformer. Another BORG feature will be a hand-rock table that has a true *Trendelenberg* at all the degrees of angulation instead of the customary three positions. It is controlled by a push button on the rocking handle, which operates a solonoid on the gear segment.

BRACKE-SEIB X-RAY CO., INC.

Booths A-169, A-171

PAUL E. BRANDWEN

Booth C-108

JOHN H. BRECK, INC.

Booth A-83

Breck industrial preparations on display here will include Breck Hand Cleaner, a bland, mild, nonirritating cleaner; Breck pH7 Protective Cream, of great value in many industrial plants where employees come in contact with irritants; Breck Water Resistant Cream, which forms a protective film of material, resistant to the action of water and water soluble substances; and Breck Work Cream, a protective cream to help prevent defatting of the hands.

GEORGE A. BREON & COMPANY

Booth A-94

Rest, a cordial welcome, and, if you're in the mood, conversation—even pertinent information—await the eager but not inexaustible conventioneer in the Breon "garden." There a lighted fountain bubbles from a vine-covered wall. Soft cushioned seats will take the weight off your feet while you renew your wind and your acquaintance with Breon representatives.

BREWER & CO., INC.

Booth C-136

BRISTOL LABORATORIES, INC.

Booths A-9, A-11

The BRISTOL LABORATORIES' exhibit will be devoted to the display of penicillin and pharmaceutical products. Qualified representatives will be on hand to assist the medical profession with any inquiries. Literature describing Bristol products will be available.

BRUSH DEVELOPMENT COMPANY

Booth C-92

THE BURDICK CORPORATION

Booths A-58, A-60

The Burdick Corporation will display their new F.C.C. approved Diathermy Unit, Model X-85, a special feature of which is the Contour Applicator; modern Infra-Red and Ultraviolet Lamps; Low Voltage apparatus; and the Rhythmic Constrictor. Visiting doctors and nurses are invited to register for a free copy of the "Syllubus," a compilation of information on the use of Physical Medicine Equipment.

BURNS CUBOID COMPANY

Booths C-145, C-147

Burns Cuboid Company will bring to the Convention a specially constructed, colorful Masonite display redesigned to show more graphically the various raises of these featherlite, metal free adapters. A companion piece will show many of the 176 size variations which permit more accurate fitting. Reprints of HYGEIA ads which tell the complete story of Cuboids will also be displayed.

BURROUGHS WELLCOME & CO. (U.S.A.) INC.

Booths A-2, A-4

Large THREE-DIMENSIONAL color photography will be used here to illustrate the important features of 'Wellcome' GLOBIN INSULIN and 'DEXIN'. Be sure to stop by to see this unusual development.

BURTON MANUFACTURING COMPANY

Booth B-79

CAMBRIDGE INSTRUMENT CO., INC.

Booth A-72

CAMEL CIGARETTES
(MEDICAL RELATIONS DIVISION)

Booths B-74, C-75

CAMERON SURGICAL SPECIALTY COMPANY

Booths C-115, C-117

Among the items to be demonstrated at the Cameron exhibit are Cauterodynes and Cauteradios for Electro-surgery, Electro-cauterization and Electro-coagulation; Coagulair-Sigmoidoscope; Electro-Diagnostic Lamps and Instrument Sets; Radiolucent Cannula; the new Flexible Gastroscopes with treated and coated lenses; Flexible Esophagoscopes, Bronchoscopes; Esophagoscopes; Laryngoscopes; Mirror, Headlites; Binocular Spectacle Loupe; Magniscope and other Specialties.

S. H. CAMP & COMPANY

Booths C-68, C-70

A series of illuminated transparencies depicting anatomical conditions before and after application of Camp Anatomical Supports will be displayed. Experts in attendance will answer questions pertaining to the scientific application of Anatomical Supports and advise regarding the availability of them in Authorized Service Departments throughout the country.

CANADIAN RADIUM AND URANIUM CORP.

Booth A-117

CARNATION COMPANY

Booths C-89, C-91

Here you will see an attractive display on Carnation Evaporated Milk - "the milk every doctor knows." Valuable information on the use of this milk for infant feeding, child feeding, and general diet, will be presented; and the method by which Carnation is generously fortified with pure crystalline Vitamin D - 400 U.S.P. units per reconstituted quart - will be explained. Interesting literature will also be available for distribution.

WILMOT CASTLE COMPANY

Booths A-30, A-32, A-34

Your inspection of the latest in Sterilizing and Lighting Equipment will be welcomed at the Castle booth. A valuable booklet entitled, HOW TO BUY A STERILIZER, will be available for the doctor or his nurse.

CENTRAL PHARMACAL COMPANY

Booth A-17

THE CENTRAL SCIENTIFIC COMPANY

Booth B-90

The item of main interest in the Central Scientific display will be the powerful Waring Blendor in actual operation—for rapid disintegration, pulping, and mixing of foodstuffs, for studies in nutrition, vitamin assay, etc, or for the preparation of vaccines, enzymes, bacteria, and viruses. Included in the display will be electronic titration-pH meters, photoelectric filter photometers, and other new instruments for research and clinical laboratory procedures.

CEREAL INSTITUTE, INC.

Booth A-16

"What Are You Doing About Breakfast?" will be the theme of the materials to be presented at the Cereal Institute exhibit. These materials have proven to be serviceable to professional leaders and teachers who are concerned with teaching the importance of an adequate breakfast in the daily diet. Complimentary copies of CEREALS AND THEIR NUTRITIONAL CONTRIBUTION, and THE CEREAL AND MILK STORY will be available.

THE CHICAGO DIETETIC SUPPLY HOUSE, INC.

Booth A-67

CHURCH & DWIGHT CO., INC.

Booth B-25

Interest in the Church & Dwight exhibit this year will center on its well-known Bicarbonate of Soda, Arm & Hammer and Cow Brands. These brands of U.S.P. quality are used extensively in Medical Practice, but this year emphasis will be placed on their value as a powder for cleaning the teeth. The Council on Dental Therapeutics has accepted the products as dentifrices. Booklets designed to stimulate child interest in Oral Hygiene will be distributed.

CIBA PHARMACEUTICAL PRODUCTS, INC.

Booths B-165, B-167

For complete information on latest developments in the use of PYRIBENZAMINE, the antihistaminic for relieving symptoms of allergy, visit the Ciba booth. Also featured will be PRIVINE Hydrochloride, the effective long lasting nasal vasoconstrictor. Representatives in attendance will gladly answer any questions you may have concerning these products and to furnish you with literature and samples.

THE CILKLOID COMPANY

Booth C-88

Visitors to this booth can examine the Perforated Form of Cilkloid and obtain information concerning its use as a Non-Adherent Direct Dressing for skin grafts, burns, ulcers, plastic surgery, etc. Industrial surgeons will also be interested in knowing about the Impervious Form of the Cilkloid for protective and occlusive dressings. Both forms will be of especial interest to hospital personnel.

CLAY-ADAMS COMPANY, INC.

Booth C-56

Clay-Adams exhibit will feature equipment for the new cytological technics, blood testing equipment, and new developments in laboratory and diagnostic equipment. There will be a display of visual aids for teaching and study including Medichromes, anatomical charts, obstetrical manikins, and osteological preparations.

CLERSITE CO.

Booth C-82

COCA COLA COMPANY

Booth A-132

"Pause...and refresh" will be the feature of hospitality centering in the Coca Cola lounge. This invitation means a pure, thirst-quenching, wholesome drink and is extended to all visitors.

WARREN E. COLLINS, INC.

Booth A-13

At Warren E. Collins exhibit will be seen a fine display of scientific respiration apparatus. These include the Drinker-Collins Duplex Respirator; the Benedict-Roth Metabolism Apparatus for routine metabolism work and lung function studies; the Collins Open-Top Oxygen Tent; and the Drinker-Collins Infant Respirator. Skilled factory technicians will be in attendance to welcome you.

COLWELL PUBLISHING COMPANY

Booth B-17

Of special interest to all physicians will be a new line of letter-size DAILY LOG history sheets, designed for general practice and most specialties. The DAILY LOG for Physicians and the regular line of card size ledgers and histories may be examined. Efficient indexing and filing of medical records will be demonstrated and questions about medical record procedures will be welcomed.

C. S. C. PHARMACEUTICALS

Booth C-139

The display of C.S.C. Pharmaceuticals will feature a large portrait of Sir Alexander Fleming, one of the pioneers in the development of penicillin. In 1929 Fleming observed that the mold, Penicillum notatum, elaborated a substance which inhibited the growth of bacteria. From this chance laboratory observation has come one of the most powerful therapeutic agents ever placed in the hands of physicians, a tribute to the scientific alertness of Fleming. The C.S.C. display will also feature full color reproductions of disease processes amenable to penicillin - C.S.C. preparations.

CONFORMAL FOOTWEAR COMPANY

Booth C-40

CONTINENTAL X-RAY CORPORATION

Booths A-18, A20

The Continental X-ray Corporation plans to feature two new developments along with their standard line of popular equipment at the Medical Convention this year. One new development is the electronic stylus orthodiagraphic attachment for fluoroscopes; the other is a 250 milliampere push button selection power unit, designed for simplicity of operation.

THE COOPERATIVE MEDICAL ADVERTISING BUREAU

Booth A-48

CORECO RESEARCH CORP.

Booth A-163

CORN PRODUCTS SALES CO.

Booths C-63, C-65

COUNCIL ON WHITE MINERAL OIL

Booth B-30

The Council on Mineral Oil will distribute an informative booklet, "What Physicians Say About Mineral Oil" and sample bottles of mineral oil at its booth. On exhibit will be photostats of Council advertisements in the Journal of the American Medical Association.

CURVLITE PRODUCTS, INC.

Booth B-122

CUTTER LABORATORIES

Booths C-163, C-165, C-167

On display in this exhibit will be the Cutter line of Intravenous Solutions in Safti-flasks with the latest expendable equipment for administration. The recent advances and additions to the blood fractions group of products will also be on display; for your inspection.

DAVIES, ROSE AND COMPANY, LTD.

Booth C-67

The current Quinidine Sulfate situation, which has been a very perplexing problem during the past few years, will be explained by representatives in the Davies, Rose exhibit. Their Tablets of Quinidine Sulfate, alkaloidally standardized, which assures uniformity in dosage, will be featured.

F. A. DAVIS COMPANY

Booth B-112

Many of the newest and most talked about books will be on display at the F.A. Davis booth. Among them: ARTHRITIS, Bach; GALLBLADDER DISEASES, Behrend; HANDBOOK OF TREATMENT, Gruber; PERIPHERAL VASCULAR DISEASES, Kramer; PEDIATRIC PROGRESS, Litchfield-Dembo; MEDICAL DIAGNOSIS, Loewenberg; CLINICAL UROLOGY, McCrea; RHINOPLASTY, Maliniac; GONIOSCOPY, Troncoso; REPARATIVE SURGERY, May; RADIOLOGY, Pillmore; TREATMENT IN GENERAL MEDICINE, Reimann; DIAGNOSTIC SIGNS, Robertson; PRE-OPERATIVE AND POSTOPERATIVE CARE, Tourish and Wagner.

DAVIS & GECK, INC.

Booth A-35

Davis & Geck, Inc., manufacturers of sterile surgical sutures, will present an armamentaria of suture-needle combinations specifically prepared for every type of surgery. Literature and technical information on sutures and wound healing will be available. This will include the D&G Manual, reprints and monographs as well as leaflets dealing with the development and improvement of D & G sutures.

DAVOL RUBBER COMPANY

Booths C-104, C-106

To this year's annual meeting of the A.M.A , the Davol Rubber Company will bring its newest medical specialties· First-Aid Tourniquet which clips instantly and holds fast, Urinal Bottle Cap and Connecting Drain Tube, two new types of T Tubes for biliary drainage, "Paris" water bottle with its air-cushioned surface --- and "Anti-Colic" brand Nurser with the "Anti-Colic" brand Nipple with an all-'round tab.

MRS. DAY'S IDEAL BABY SHOE COMPANY

Booth C-25

A vitit to MRS DAY'S IDEAL BABY SHOE exhibit will reveal a complete line of baby shoes in choice materials. IDEALS take care of the baby through the four stages - crib, soft soles, intermediate soles and hard soles. Doctors are cordially invited to call at booth number C-25.

DENOYER-GEPPERT COMPANY

Booth A-101

Denoyer-Geppert Company, Educational Publishers, will display two life size anatomical oil paintings from a series of ten now in preparation, and two reproductions of these originals, just completed. Also on display will be a selection of the world famous anatomical models by Dr. Auzoux, France; prepared human skulls and bone preparations, and some of their own anatomical models and corrosion specimens.

THE DENVER CHEMICAL MFG. CO., INC.

Booth B-78

Exhibited here will be the Galatest for the instantenous determination of urine sugar, and Acetone Test (Denco) for the detection of acetone in urine will be exhibited. You will be especially interested in a demonstration of these "spot tests" for sugar and acetone. Galatest and Acetone Test (Denco) offer advantages of accuracy, simplicity and economy in routine urinalysis.

DEPUY MANUFACTURING COMPANY

Booth B-158

DEVEREUX SCHOOLS

Booth C-61

Devereux Schools will acquaint physicians with their facilities for educating and treating children having academic or emotional difficulties. Twelve Devereux Schools in Pennsylvania and the Devereux Ranch School in California offer controlled environment and modern training, shaped to each child's needs. The residing psychiatrist, physician and psychologist, cooperate with the referring physician in his plans for the child's training and care.

DEVILBISS COMPANY

Booths C-105, C-107

Kodachrome transparencies edpicting the distribution of aerosols in the lungs and bronchi is a feature of the DeVilbiss Company exhibit. This data supports clinical investigations and experimental work with aerosols of penicillin, streptomycin, epinephrine, and other substances. Instruments for all types of spray application will be displayed.

DIAPHAGM & CHEMICAL COMPANY

Booth C-140

DICTOGRAPH PRODUCTS, INC.

Booth C-113

THE DIETENE COMPANY

Booth C-34

At the Dietene Company exhibit you will discover a really palatable high protein diet supplement--MERITENE. Dietene Reducing Supplement and the 1000 calorie *Dietene Reducing* Diet will also be featured. Both MERITENE and DIETENE are Council-Accepted. A complimentary, personal type diet service will be available to physicians.

DOAK COMPANY, INC.

Booth C-174 (East ½)

DUKE LABORATORIES, INC.

Booth A-5

Duke Laboratories will exhibit Mediplast, elastic adhesive compress, wrapped individually and sterilized in conformity with regulations of the U.S. Food and Drug Administration; Elastoplast; Aquaphor; Basis Soap; Tecto; and Nivea--The Prescriber's Cosmetics.

E. I. DU PONT DE NEMOURS & CO., INC.

Booths C-96, C-98

Du Pont X-ray Films and Chemicals, "Patterson" X-ray Screens, and actual radiographs will be exhibited here. Of special interest to the photographic hobbyists will be 'Defender" Films, Papers, and Chemicals. This new exhibit of the Du Pont Photo Products Department of E. I. du Pont de Nemours & Co., Inc. will be finished in black and gray.

DUREX PRODUCTS, INCORPORATED

Booth A-131

Contraceptive specialties by Durex will highlight this exhibit. Devices and unusual packagings *never before shown* at an A.M.A. Convention, including the Bow-Bend diaphragm (hinged rim) will be of particular interest. Complete contraceptive sets in the new compact and sanitary Duracase will be appreciated by the physician and patient alike. Latest clinical information on both Lactikol Jelly and Lactikol Creme will be available.

E & J MANUFACTURING COMPANY

Booth C-72

EASTMAN KODAK COMPANY

Booths B-47, B-49, B-51

Full-color Kodachrome transparencies and radiographs to illustrate the theme, "Picture the Patient's Progress"...with photograph after photograph...with radiograph after radiograph--will highlight the Eastman exhibit. The cases selected emphasize the value of a series of photographs of radiographs in depiciting the patient's progress. Instructive diagrams will be included. Supplementing the transparencies and radiographs will be displays of photographic and x-ray products.

EATON LABORATORIES, INC.

Booth A-133

Furacin Soluble Dressing and Furacin Solution, topical antibacterial preparations which possess a wide antibacterial spectrum without injuring tissue, will catch your interest at the Eaton exhibit. Other specialties to be displayed include, Lorophyn Suppositories and Lorophyn Jelly, contraceptives of proven clinical effectiveness, containing a powerful spermicide.

EDIN ELECTRONICS COMPANY

Booth A-37

THOMAS A. EDISON, INC.

Booth A-149

J. EDWARDS & COMPANY

Booth B-50

EISELE & COMPANY

Booth C-168

ELECTRO-PHYSICAL LABS. INC.

Booth A-75, A-77

ELECTRO SURGICAL APPLIANCE CORP.

Booth A-139

Among the new items to be shown for the first time by Electro Surgical Appliance Corp. will be a fully rectified and filtered ELECTRONIC SCALPEL of unusual cutting qualities. This Scalpel is non feradic and does not interfere with radio. Several new developments in Proctal Snares and dessication instruments will also be shown.

J. H. EMERSON COMPANY

Booth A-107

The LUNG IMMOBILIZING CHAMBER which provides complete bilateral lung rest-without surgery or pneumothorax will be shown in the J.H. Emerson Company's display. Dramatic reports have shown that the very sick tuberculosis patients receive benefits by this new treatment.

ENCYCLOPAEDIA BRITANNICA, INC.

Booth C-32

ENDO PRODUCTS INC.

Booths B-161, B-163

Various Endo prescription and ampule specialties will be featured. Among the Council-accepted products shown will be Mesopin, selective gastrointestinal antispasmodic; Estromone, for estrogenic therapy; Norodin Hydrochloride, psychomotor stimulant and anti-depressant. Samples and literature will be available for distribution.

ETHICON SUTURE LABORATORIES

Booths B-121, C-127

Ethicon Sterile Pack Sutures, a new metal suture storage canister containing tubed sutures, packaged sterile and ready for use, will be the feature of the exhibit Ethicon Suture Laboratories has prepared for the A.M.A. Chicago Meeting. By eliminating the necessity for washing tubes and buying suture jars, Ethicon Sterile Pack Sutures save the Hospital an estimated $10 per bed per year, and four nurse hours per 100 beds per week.

ETHIX CORPORATION

Booth B-33

In their initial exhibit, Ethix Corporation will present a series of distinguished *formulas*, each one supplying a specific need--all of them together forming an intergrated line of Hypo-Allergenic Cosmetic and Dermatological Preparations.

EUREKA X-RAY TUBE CORP.

Booth C-149

EVAPORATED MILK ASSOCIATION

Booth B-58

The Evaporated Milk Association will display publications dealing with the properties and uses of evaporated milk in infant feeding, child nutrition, maternal welfare, social welfare, public health, and general nutrition. These publications, available without charge, are designed for professional people, and for distribution to those whom they serve. Register at Booth B-53 for these useful and helpful materials.

EXERCYCLE CORPORATION

Booth C-26

So many physicians have bought Exercycle for their personal use that Exercycle for the first time is being exhibited at an A.M.A. Convention. Exercycle operated by motor automatically provides cycling, riding, rowing, or swimming action, either separately or in combination, with varying degrees of intensity ranging from passive (relaxed) to mild or active. Excellent also wherever controlled exercise is indicated.

EXPERT BEDDING COMPANY

Booth B-119

FANCEE FREE MFG. CO.

Booth C-182

Fancee Free, a simple little elastic garter belt that fits around the waist in back and below the abdomen in front to eliminate all pressure, will be presented in booth C-182. It is excellent for maternity patients or others who must avoid pressure or binding. Two snap on satin tabs transform the Fancee Free into a combination garter belt and sanitary belt ending all "Double Belt" trouble.

H. G. FISCHER & CO.

Booths A-158, A-160, A-162

Interest at the H. G. Fischer exhibit will center on their New DeLuxe "RF-200" X-Ray Unit. Full 200 milliampere capacity, automatic controls of advanced design, rugged construction and fine appearance, are some of its features. Their new FCC Type Approved diathermy units will be demonstrated:

FISHER-STEVENS SERVICE

Booth C-102

This exhibitor maintains a mailing list of all practicing physicians in the entire country. The list is used by pharmaceutical manufacturers to distribute literature and samples by mail. Stop at booth C-102 and learn more about the direct mail campaigns of the Fisher-Stevens Service.

C. B. FLEET CO., INC.

Booth A-33

Latest information on the increasing popularity of Phospho-Soda (Fleet), the pure, stable, aqueous concentrate of the two U.S.P. sodium phosphates, will be available at the C.B. Fleet exhibit.

FLINT, EATON & COMPANY

Booth C-171

Recent research on Choline has introduced new hope for the sufferer from early and late cirrhosis of the liver. An easy and acceptable way of administering Choline to your patients will be displayed at Flint Eaton's booth C-171. The product, Choline Dihydrogen Citrate (Flint), is extremely palatable. A very comprehensive digest covering the present status of Choline therapy will be available.

FLORIDA CITRUS COMMISSION

Booth A-151

FOLEY MANUFACTERING COMPANY

B-93

Facts about the Foley Food Mill and an interesting demonstration showing how it saves time and food for the homemaker in the preparation of fresh cooked vegetables and fruits for all smooth diets may be had in Booth B-93.

THE FOREGGER CO. INC.

Booth A-141

The Foregger Company will show equipment for Endotracheal Anesthesia including some newly developed items of interest to Surgeons as well as Anesthetists. Recent developments in Anesthesia equipment will also be on display including special equipment for anesthetizing new-born Infants for the Blalock Operation, repair of cleft palate and similar procedures.

GAMMA INSTRUMENT CO., INC.

Booth C-64

GASTRO-PHOTOR LABORATORIES CORP.

Booth A-15

The new, $500, model of the Gastro-Photor -- "The Camera for Photographing the Interior of the Stomach" will be the item of interest here. With one exposure this Stomach Camera provides 16 gastrophotographs which make possible the diagnosing of ulcers hidden within rugal folds or in locations inaccessible to X-Ray observations. Samples of gastrophotographs will be displayed for first-hand observation.

GENERAL ELECTRIC COMPANY (LAMP DEPT.)

Booth A-24

The power of germicidal lamps to control mold growths and of infrared energy to penetrate human flesh will highlight the G-E Lamp exhibit. Portions of the live mold on various foods will be placed in a "germicidal shadow" to allow the mold to flourish. Physicians will be able to make a direct examination of the results; also to conduct on-the-spot measurements of the pentrating power of infrared radiant energy from heat lamps. Recording equipment will measure the penetration of the energy through human flesh independently of a subject's personal judgment.

GENERAL ELECTRIC X-RAY CORPORATION

Booths A-21, A-22, A-23, A-25

GENERAL FOODS CORPORATION

Booths A-143, A-145, C-120

GERBER PRODUCTS COMPANY

Booth B-111

GOMCO SURGICAL MANUFACTURING CORP.

Booth C-74

THE B.F. GOODRICH COMPANY

Booth A-166

The Sundries Division of The B.F. Goodrich Company will show samples of its entire line of rubber and Koroseal surgical goods in an attractive booth. Featured will be the new line of deluxe hospital specialties and the new all color catalog.

GRADWOHL LABORATORIES

Booths B-8, B-10

This interesting exhibit will cover the activities of Gradwohl Laboratories--the making of laboratory reagents and Government licensed testing sera; training of laboratory technicians; and the publication of a journal devoted to laboratory subjects, called LABORATORY DIGEST. Special features will be the daily demonstration of Anti-Rh tests, a display of material for the Papanicolaou diagnosis of carcinoma, and special stains and technique for this work.

GRASS INSTRUMENT CO.

Booth A-179

GRUNE & STRATTON, INC.

Booths B-13, B-15

Outstanding among new publications for general practice and specialties to be displayed here include Neuhof: VENOUS THROMBOSIS AND PULMONARY EMBOLISM; Daley and Miller: PROGRESS IN CLINICAL MEDICINE; Berson: ATLAS OF PLASTIC SURGERY; Fitzwilliams: CANCER OF THE BREAST; Hill and Dameshek: Rh FACTOR; Ponder: HEMOLYSIS; Spiegel (Editor): PROGRESS IN NEUROLOGY AND PSYCHIATRY VOLUME III; Wolberg: MEDICAL HYPNOSIS; Bellak: DEMENTIA PRAECOX. All periodicals of the British Medical Association will be available.

HAMILTON MANUFACTURING COMPANY

Booths B-63, B-65, B-67

Three suites of Examining Room Furniture will be displayed in the Hamilton exhibit: Deluxe Nu-Tone, the distinctive and modern Nu-Trend, and the professionally styled Steeltone. Also shown will be the No. 9905-B-AP All-Purpose Examining Chair Table, the No. 9902 Pediatric Table, the No. 9595 EENT Cabinet, and representative items of business office and reception room furniture.

HANOVIA CHEMICAL & MFG. COMPANY

Booths B-9, B-11

Modern ultraviolet self-lighting quartz lamps for orificial and body radiation, as well as Sollux Radiant Heat Lamps, jacketed type quartz germicidal lamps for operating rooms, nurseries and isolation wards and black light for diagnostic purposes will be on display in the Hanovia exhibit. Competent and courteous representatives will be at your disposal.

THE HARROWER LABORATORY

Booths A-27, A-29

H. J. HEINZ COMPANY

Booths C-97, C-99

PAUL B. HOEBER, INC.

Booth B-1

PAUL B. HOEBER, Inc., Medical Book Department of Harper & Brothers, will display advance proofs of two significant new books, Coley's NEOPLASMS OF BONE and Kaplan's RADIATION THERAPY. A complete line of distinguished titles, including the new 2nd Edition of Ridley & Sorsby's MODERN TRENDS IN OPHTHALMOLOGY and the new MacKenna's MODERN TRENDS IN DERMATOLOGY will also be available for inspection.

HOFFMANN-LAROCHE, INC.

Booth B-20

The Roche exhibit will be devoted exclusively to the council-accepted specialty, PROSTIGMIN. The many recognized uses of PROSTIGMIN are always of interest to physicians who are invited to stop at booth B-20. A staff of experienced representatives will be pleased to discuss PROSTIGMIN and other Roche specialties of interest to them.

HOLLAND RANTOS COMPANY, INC.

Booth A-73

KOROMEX JELLY and KOROMEX CREAM will be featured here. You may recall it was the Holland-Rantos Company, Inc., that "pioneered" the introduction of modern contraceptive technique frequently referred to as the Koromex Method. The medical background and clinical use of KOROMEX JELLY dates back to 1925. Medical service representatives will be on hand to discuss the latest data on KOROMEX JELLY and CREAM.

HOLLISTER-STIER LABORATORIES

Booth B-29

The spotlight at the Hollister-Stier booth will be on the beautiful plastic case accommodating the new and improved dropper vial for diagnostic allergens. Improved diagnostics are in the making, too. The complete and personalized allergy service of a pioneer and "specialist" in allergy - Hollister-Stier Laboratories - will be of interest to all physicians.

HOSPITAL LIQUIDS, INC.

Booth B-98

RICHARD HUDNUT

Booths A-118, A-120

THE HYGEIA NURSING BOTTLE CO.

Booth A-122

The new, improved Hygeia Nursing Bottle with extra capacity over 4 and 8 ounces will draw interest at booth A-122. Learn why prescribing the Hygeia Unit - including nipple, bottle, and glass cap - will help mothers and hospitals overcome their feeding problems. A trained representative will be in attendance.

HYGEIA, THE HEALTH MAGAZINE

Booths A-44, A-46

In the HYGEIA booth, you will find a pictorial representation of editorial contributors, the processes of editing, the methods used for screening and approving advertising and the various types of readers who benefit from this health magazine. Also presented is a series of sequence lighted color transparencies showing how HYGEIA's health information is used by professional, educational, and family groups.

ILLE ELECTRIC CORPORATIONS

Booth C-125

Ille Electric Corporation will demonstrate how the care of infantile paralysis, arthritis, and other disabling conditions, can be greatly improved by the use of Hydromassage Subaqua Therapy Tanks. They will also display an improved Mobile Whirlpool Bath with New Mobile Adjustable High Chair.

INHALATIONAL EQUIPMENT COMPANY, INC.

Booth A-165

Special attention is expected to focus on the Inhalational Equipment display. The exhibit will present the mechanics of Aerosol Therapy in the treatment of chronic and acute lung and sinus infections. Included will be a variety of methods of administering Aerosol Therapy, utilizing the Council-accepted I.E.C. Nebulizer as the basic unit, together with accessory equipment as a means of Aerosol administration.

INTERCHEMICAL CORPORATION - BIOCHEMICAL DIVISION

Booth A-127

The Biochemical Division will feature its modified protein hydrolysate, "ELAMINE Lyophilized," which has been specifically designed for intravenous amino-acid therapy. Visitors to the booth will have an opportunity to visualize several important steps in the manufacture of ELAMINE, particularly those dealing with the method of "freeze-drying." Representatives will be present to discuss parenteral alimentation.

INTERNATIONAL VITAMIN CORPORATION

Booths B-16, B-18

At the I.V.C. Booth there will be a full array of Council-accepted vitamin products. An especially interesting Vitamin "A" configuration will be shown in color transparency. Well-trained representatives and an M.D. will be in attendance at all times to describe and explain the uses of I.V.C. products.

IODINE EDUCATIONAL BUREAU, INC.

Booth B-85

JANEIL SHOP FOR HANDICAPPED GIRLS

Booth C-38

Here will be displayed pictures and charts of the various departments and activities of Spalding School for Handicapped Children, one of the largest and finest public schools of its kind in the world. Janeil Shop, a Sheltered Work Shop at Spalding, trains badly handicapped girls to sew. Their products, which are sold for their benefit, will be on display in Booth C-38. Guests will be welcome.

JOHNSON AND JOHNSON

Booths A-26, A-28

Hemo-Pak Hemostatic Absorbable Surgical Dressings will be the main feature in the Johnson and Johnson display of latest developments in surgical dressings.

JONES METABOLISM EQUIPMENT COMPANY

Booth C-157

A feature of the Jones Metabolism Equipment exhibit will be the JONES SUPER-MOTOR-BASAL, with its exclusive feature "Two Machines In One"-- a standard-size unit for average cases built into a double-size unit for convenient handling of all extreme cases. Technicians of many years' experience will be available for answering all questions on metabolism testing.

JORDAN PUMP COMPANY

Booth A-153

The Jordan Pump Company, for the past eighteen years builders of small, efficient, and inexpensive pressure and vacuum Units, will show vacuum and pressure Units and various other items adaptable to the medical and surgical fields. Two Units are especially adaptable to the use of Penicillin Inhalation Therapy.

"JUNKET" BRAND FOODS

Booths B-106, B-108

The importance of rennet in infant and adult nutrition and the value of rennet desserts in both normal and restricted diets will be explained here. Enlarged photos illustrate the action of the rennet enzyme in producing softer, finer, more readily-digestible milk curds. Authoritative literature describing dietary applications of rennet products and complimentary packages of "Junket" Rennet Powder and "Junket" Rennet Tablets will be available.

KANSAS CITY ASSEMBLAGE COMPANY

Booth C-100

The new and improved Padgett-Hood Dermatome, exhibited for the first time at an American Medical Association Convention, will feature an aluminum drum which gives increased lifting power, retains nearly all cement on the drum when skin is stripped from drum, automatically aligns the knife edge with the drum surface, and sets the knife edge to register with the scale.

THE KELLEY KOETT MANUFACTURING CO.

Booths A-62, A-64, A-66, A-68

Some new and interesting developments in X-ray equipment may be seen in the Kelley-Koett booth. These include a new 300 MA Generator and Control finished in beautiful Kelekote, designed to cover the entire range of radiographic and fluoroscopic requirements; and a new, inexpensive Pediatrician's Fluoroscopic Table, designed under the direction of a Pediatrician, to meet all Pediatric X-ray requirements.

KEYSTONE VIEW COMPANY

Booth A-55

Keystone will exhibit a new Telebinocular and Ortho-Trainer for use of transparencies, together with the Occupational Visual Service for industrial vision testing; Overhead Projector for 3¼ x 4 inch slides, 2 x 2 inch transparencies, and etched glass plates; home training material for use in all types of visual discomfort; and a new technique in squint training with the Keystone Stereo-Motivator.

KIDDE MANUFACTURING CO., INC.

Booths C-101, C-103

Two distinct features will comprise this exhibit: a display of the new *Kidde* Utero Tubal Insufflator with GASOMETER pressure control, providing diagnostic and therapeutic use of Carbon-Dioxide or opaque oil; and the increasingly popular *Kidde* Dry Ice Apparatus for use in the treatment of superficial skin lesions.

H.W. KINNEY AND SONS

Booths C-109, C-111

LAKESIDE LABORATORIES, INC.

Booth A-183

LANTEEN MEDICAL LABORATORIES

Booth C-80

The Lanteen exhibit will employ a new landscape photo mural background which has received many fine comments and compliments at recent medical meetings. Visiting physicians will find it worthwhile to see this attractive exhibit.

LEA & FEBIGER

Booth B-19

The Lea & Febiger exhibit will be of particular interest because of such outstanding new books and new editions as Ormsby and Montgomery--DISEASES OF THE SKIN; Frohman--BRIEF PSYCHOTHERAPY; Gray--ANATOMY OF THE HUMAN BODY; Buchanan--FUNCTIONAL NEURO-ANATOMY; Partipilo--SURGICAL TECHNIQUE AND PRINCIPLES OF OPERATIVE SURGERY; Krimsky--BINOCULAR IMBALANCE; Kraines--THE NEUROSES AND PSYCHOSES; Spaeth--OPHTHALMIC SURGERY; Ballenger--DISEASES OF THE NOSE, THROAT AND EAR; Lewin--THE FOOT AND ANKLE and many others.

LEDERLE LABORATORIES

DIVISION AMERICAN CYNAMID COMPANY

Booths C-119, C-121, C-123

The Lederle exhibit, devoted entirely to Council-accepted products, will merit the thoughtful attention of every physician. Trained individuals will be available to assist the visiting physician in every way possible regarding the field of biologicals, pharmaceuticals, and diagnostic procedures.

LIBBY, MCNEILL & LIBBY

Booth A-150

The advantages of the Libby Strained and Homogenized Foods will be described in the Libby, McNeill & Libby booth. Discussions pertaining to the dietary management of infants and older babies will be welcomed.

THE LIEBEL-FLARSHEIM COMPANY

Booth A-71

The special features of the Liebel-Flarsheim exhibit will be a display and demonstration of their latest model diathermy and Bovie electrosurgical equipment. Capable representatives will be on hand at all times to answer your questions about physical therapy and electrosurgical apparatus. Plan to inspect the interesting features of this exhibit.

ELI LILLY AND COMPANY

Booths B-40, B-42, B-44

LINCOLN LABORATORIES

Booth A-135

THE LINDE AIR PRODUCTS COMPANY

Booths B-141, B-143

A growth chart representing the thirty year rise of oxygen therapy importance in medicine will be featured here. Factors causing this rapid growth will be clearly shown. Supplementing the chart, Linde oxygen and oxygen therapy equipment will be exhibited, and the Beckman magnetic oxygen analyzer will be demonstrated. Special representatives will welcome your consultation on problems of oxygen and oxygen therapy apparatus.

J. B. LIPPINCOTT COMPANY

Booths C-1, C-3, C-5

J.B. Lippincott Company will present their Selected Professional Books, by outstanding authors. The 'pulse of practice,' gauged constantly by Lippincott, centers in an advisory board of active clinicians who constantly review the current and coming trends. Due to this publishing policy, more doctors look to Lippincott for timely, practical, dependable information of authority in all fields of medicine, surgery, dentistry, nursing and pharmacy.

LUZIER'S, INC.

Booth B-38

M & R DIETETIC LABORATORIES, INC.

Booth B-52

Similac, a food for infants during the all-important first year of life, will be displayed in booth B-52. Representatives will be in constant attendance and will welcome the opportunity to discuss the merits and suggested applications of the product in the feeding of the normal infant, as well as the infant requiring an individualized formula.

MACALASTER BICKNELL COMPANY

Booth A-85

MACHLETT LABORATORIES, INC.

Booth B-174

THE MACMILLAN COMPANY

Booth A-69

PSYCHIATRY IN A TROUBLED WORLD, a new book by Dr. William C. Menninger of the Menninger Foundation, will be offered by Macmillan. "Yesterday's war" from the psychiatric standpoint and "today's challenge"—a plea for application of psychiatric measures to present perplexing problems—is discussed. GLOMERULAR NEPHRITIS (Macmillan), containing Dr. Thomas Addis' method of diagnosing and treating Bright's Disease will interest the General Practitioner.

THE MAICO COMPANY, INC.

Booths C-84, C-86

MALLINCKRODT CHEMICAL WORKS

Booth C-138

THE MALTINE COMPANY

Booth C-50

MANHATTAN UNIFORM COMPANY

Booth C-146

The various types of professional garments for the office or the hospital will be on display in the Manhattan Uniform exhibit, or illustrated in their catalogue. These uniforms which are tailored-to-measure may be ordered in any of fifteen (15) materials including rayon. Sample swatches will be available.

MARCELLE COSMETICS

Booth B-56

The growing interest in Allergy will make the exhibit of Marcelle Hypo-Allergenic Cosmetics particularly attractive to all visitors. The fact that Marcelle formulas omit all known allergens, highly recommends these cosmetics for all persons with sensitive skins, or those with allergy problems--or as a precautionary measure. Sample cosmetics and formularies will be available to allergists, dermatologists, or all physicians.

THE S.E. MASSENGILL COMPANY

Booth C-156 (west ½)

F. MATTERN MFG. CO.

Booths A-41, A-43, A-45, A-47

A visit to the MATTERN Booths will enable you to personally examine the very latest and most modern line of Mattern X-Ray Apparatus to satisfy your every need. Qualified personnel will be pleased to answer your questions.

MCFEDRIES X-RAY COMPANY

Booth C-169

MCKESSON APPLIANCE COMPANY

Booths C-120, C-122

McKESSON & ROBBINS, INC.

Booths B-164, B-166

A display of accepted vitamin products and historical data showing development of the House of McKesson since 1833 will be featured here. Some of the modern laboratory procedures will be demonstrated.

MCNEIL LABORATORES, INC.

Booth A-140

MEAD JOHNSON & COMPANY

Booths B-175, B-177, C-41, C-43

Because of the increasing interest in therapeutic effects of protein, Mead Johnson & Company will devote booths C-41 and C-42 to some of the newer aspects of the subjects. Among the products to be displayed, in connection, are: Amigen, Protolysate, Nutramigen, Alacta, Casec, and Protenum. In booths B-175 and B-177, Dextri-Maltose will be featured. The use of cow's milk, water, and carbohydrate mixtures represents a system of infant feeding that consistently, for over three decades, has received universal pediatric recognition. No carbohydrate employed in this system of infant feeding enjoys so rich and enduring a background of authoritative clinical experience as Dextri-Maltose.

THE MEDICAL BUREAU

Booth C-18

In Booth C-18, the Medical Bureau, an organization serving as counselors in problems of medical and hospital personnel, will offer its facilities. Recommendations can be made of Diplomates of the American Boards, younger physicians interested in further training or assistantships, general practitioners, administrators, supervising and staff nurses, scientists, laboratory technicians, dietitians, and social workers.

MEDICAL CASE HISTORY BUREAU

Booth B-14

Exhibited here will be an inexpensive case history system which shows at a glance the complete history, development, and treatment. Of special interest is the unique method by which cases may be cross-indexed according to the disease directly upon the patient's history chart. Representatives in the booth will gladly demonstrate how these records are actually kept in the files.

MEDICAL FABRICS, INC.

Booth C-112

MEDICAL FILM GUILD

Booth A-97

MEDICAL MAILING SERVICE, INC.

Booth A-31

THE MEDICAL PROTECTIVE COMPANY

Booth B-62

The Medical Protective representatives will be at your service in booth B-62 to present their protection plan, and to explain the peculiar relations of the doctor to the law which governs your practice, or to discuss any particular phase of professional liability in which you are especially interested.

THE MENNEN COMPANY

Booth B-53

The Mennen Company will exhibit their two baby products - Mennen Baby Oil and Mennen Baby Powder. The Baby Oil is now being used routinely by the majority of hospitals that are important in maternity work.

MERCK & COMPANY, INC.

Booths C-21, C-23

THE WM.S. MERRELL COMPANY

Booth B-73

METRO-TEC COMPANY

Booth C-130

THE WM. MEYER CO.

Booth C-118

MICROTONE COMPANY

Booths A-78, A-80

THE C. V. MOSBY COMPANY

Booths C-4, C-6

A wealth of new and timely medical literature will be available for examination at the Mosby exhibit. Some of the very new releases to be shown will include Crossen OP[illegible], Patten-ger TUBERCULOSIS, Gra [illegible] METHODS AND DIAGNOSIS, [illegible] SOMATIC DIAGNOSIS AND [illegible] Willis PATHOLOGY OF TUMOURS, Ilgenfritz PREOPERATIVE AND POSTOPERATIVE CARE, Muncie PSYCHOBIOLOGY AND PSYCHIATRY, Mettler NEUROANATOMY, and the BRITISH SURGICAL PRACTICE.

MOTHERS' AID OF THE CHICAGO LYING-IN HOSPITAL

Booth C-38

The Mothers' Aid, an auxiliary of Chicago Lying-in Hospital, will present two renowned publications - Our Baby's First Seven Years' record book* gift for the mother and scrap book for the toddler. Their sale supports medical research to benefit mothers the world over. Available to hospitals for patients, gift shops and auxiliary earning funds.

* 20th printing - 700,000 copies sold.

V. MUELLER & COMPANY

Booths B-125, B-126, B-127, B-128

Two separate sections of the V. Mueller & Company exhibit will facilitate your inspection of the newest surgical equipment. One section will be devoted entirely to the latest in fine furniture and office equipment. Across the aisle, two additional booths will display interesting new instruments, both standard and special, for all several fields of surgery.

NATIONAL ASSOCIATION OF MARGARINE MANUFACTURERS

Booth B-110

Information on margarine, its ingredients and manufacture, and its role in sound nutrition may be found in Booth B-110. The National Association of Margarine Manufacturers invites your questions and views on the place of margarine in the diet. Current margarine literature and taste samples of margarine are available gratis.

NATIONAL DAIRY COUNCIL.

Booth C-48

"Food Makes a Difference," with emphasis on "Well-Fed Mothers ... Healthier Babies," will dramatize the National Dairy Council booth. The influence of diet during pregnancy upon the physical condition of the infant at birth, as shown by studies of the Department of Maternal and Child Health, Harvard School of Public Health, will be of special interest. Reprints interpreting the study will be available at the booth.

NATIONAL DAIRY PRODUCTS COMPANY, INC.

Booth C-114

Formulac infant food, a concentrated milk containing all the vitamins and minerals considered essential, will be featured in this exhibit. Since its introduction two years ago, Formulac has developed to the point where today it is generally accepted as a flexible, protective formula preparation. Representatives will be glad to explain its properties and to make it available at your hospital.

NATIONAL DRUG COMPANY

Booths C-152, C-154

THE NATIONAL ELECTRIC INSTRUMENT CO., INC.

Booth B-12

The National Electric Instrument Co., Inc., manufacturers of famous "National" illuminated diagnostic and cautery equipment, has completed extensive plans for demonstrating the uses of various surgical and ophthalmic products of interest to all specialists and general practitioners. Spotlighted for top interest is the new National Quaddiac Ophthalmoscope with instantly variable apertures and color filters.

NATIONAL INSTITUTE OF DIAPER SERVICES, INC.

Booth A-161

It does make a difference what diaper service a doctor recommends, says the NIDS whose exhibit may be seen here. Members now serve 150 metropolitan areas, and are the only diaper "service" operating under a compulsory national laboratory control which assures physicians that their diapers are safe. There is such a thing as a "prescription diaper service." Look for the NIDS Safety Seal, and stop at Booth A-161 for a bank to take home to the kiddies.

NATIONAL LIVE STOCK AND MEAT BOARD

Booth C-44

THOMAS NELSON & SONS

Booth A-14

Thomas Nelson and Sons will show advance proofs of the first of a new line of bound books - VIRUS DISEASES OF MAN, Second Edition, by C. E. van Rooyen and A. J. Rhodes, of the University of Toronto. Thomas Nelson and Sons are publishing this completely revised and enlarged edition as a result of insistent demand. The regular line of loose-leaf publications will also be displayed.

NESTLE'S MILK PRODUCTS, INC.

Booth B-149

For your relaxation the Nestle Company cordially invites you to enjoy a delicious hot cup of Nescafe. And, for your information, especially qualified representatives will be on hand to answer your questions on any of Nestle's milk products - used for babies 'round the world. New pieces of valuable professional literature will be available.

NORTH AMERICAN PHILIPS CO., INC.

Booths A-113, A-115

NOVOCOL CHEMICAL MFG. CO., INC.

Booth C-180

MONOCAINE HCl and MONOCAINE FORMATE, widely used, potent anesthetics, the latter for spinal anesthesia, will be displayed in the Novocol Chemical Manufacturing Company booth. The convenient and economical ANESTUBE (cartridge) system will be gladly demonstrated by competent representatives.

OBRIG LABORATORIES, INC.

Booth A-147

A feature of the exhibit of Obrig Laboratories, pioneer in the manufacture of plastic contact lenses, will be an automatic slide film showing the use of contact lenses in various eye conditions.

THE OHIO CHEMICAL & MFG. CO.

Booths A-119, A-121, A-123, A-125

LYDIA O'LEARY, INC.

Booth C-170

ORTHO PHARMACEUTICAL CORPORATION

Booth B-173

Featured here will be the well-known line of Ortho specialties for the control of conception, including Ortho-Gynol, Ortho-Creme and Ortho Diaphragms as well as Ortho Sets. Ortho Professional Service Representatives will be on hand to discuss these items with you at your convenience.

ORTHOMATIC MATTRESS COMPANY

Booth C-144

On display here will be the new Air Foam Mattress, a recent development of Orthomatic Mattress Company. Its porous construction, anatomically correct 'cushioning,' flexibility, etc., make it particularly beneficial in bone cases, low back conditions, etc. Additional information will be available at Booth C-144.

ORTHOPEDIC FRAME COMPANY

Booths C-158, C-160

The Orthopedic Frame Company will announce a new and important tool for the Orthopedic Surgeon - the Stryker Oscillating Bone Saw. On display will also be found an instrument with many possibilities for the Orthopedic Surgeon. The oscillating blade makes rapid, safe cuts in bone. The oscillating motion makes possible a variety of cuts not possible with a circular saw.

OXFORD UNIVERSITY PRESS, INC.

Booth B-124

A visit to Oxford's complete showing of new books by American authors will be worth your while. Important titles include DETAILED ATLAS OF THE HEAD AND NECK, by Truex and Kellner; JAUNDICE, ITS PATHOGENESIS AND DIFFERENTIAL DIAGNOSIS, by Movitt; SYMPOSIUM ON ENDOCRINOLOGY OF NEOPLASTIC DISEASES, edited by Twombly and Pack; HODGKIN'S DISEASE AND ALLIED DISORDERS, by Jackson and Parker; MODERN TREATMENT OF PEPTIC ULCER, by Windelstein; HEADACHE AND OTHER HEAD PAIN, by Wolff; TREATISE ON SURGICAL INFECTIONS, by Meleney. DIABETES AND ITS TREATMENT, by Barach.

THE G. H. PACKWOOD MFG. CO.

Booth C-30

The G. H. Packwood Manufacturing Company will again present it nationally distributed PAXLANOSAV HEAVY DUTY Granulated Skin Cleanser. This PAX Skin Cleanser contains exclusive PAXLANOSAV BLENDED EMOLLIENT combining over 3% anhydrous USP lanolin plus additional percentages of other fine emollient oils. PAXLANOSAV HEAVY DUTY quickly develops exceptionally profuse lather, remains free flowing, and can be used in good commercial granulated or powdered soap dispensers.

PARAVOX, INC.

Booth C-42

The newest Paravox Hearing Aids, including new adaptations of printed circuits will be on display here. Background display will feature pictorially the "usual HEARzone". Included in the exhibit will be samples of internal-type plastic chassis, the new magnetic receiver, and several printed circuit panels, also a new type of 100 hour, carbon-zinc "A" battery.

PARKE, DAVIS & COMPANY

Booths B-168, B-170, B-172

THE E. L. PATCH COMPANY

Booths C-14, C-16

To any physician concerned with the treatment of functional constipation, The E. L. Patch exhibit will hold a special attraction. On display will be the three types of Kondremul—Plain, with Cascara, and with Phenophthalein. You won't want to miss this interesting exhibit.

PEERLESS X-RAY LABS. AND MFG. CORP.

Booths B-86, B-88

THE PELTON AND CRANE COMPANY

Booths C-11, C-13

PENICILLIN MACHINE CO.

Booth C-66

PERKIN-ELMER CORPORATION

Booth B-117

MURLE PERRY

Booth B-46

A Colostomy and Ileostomy Appliance of unusual design will be exhibited by Murle Perry. Made of 1/8" clear plastic in several sizes and models with interchangeable inserts which enable proper fitting of all stomas, regardless of location. Latest model separates like two saucers for thorough and easy cleaning. Cellulose pad adds to comfort.

PET MILK SALES CORPORATION

Booths B-41, B-43, B-45

An actual working model of a milk condensing plant in miniature will be exhibited by the Pet Milk Company. this exhibit offers an opportunity to obtain information about the production of Pet Milk, its use in infant feeding, and the time-saving Pet Milk services available to physicians. Miniature Pet Milk can's will be given to the physicians who visit the Pet Milk booth.

PETRA MANUFACTURING COMPANY

Booth C-110

Petra Manufacturing Company will exhibit a complete line of attractive, protective KRESTEX Plastic Aprons for the doctor, surgeon, nurse, and office assistant, also utility covers, pillow cases, mattress covers, and yard goods. KRESTEX is water repellent, acid, liquid, dust, dirt, and chemical resistant: Garments are easy to clean; a whisk of a damp cloth will wipe off any accumulations on the material.

PHILIP MORRIS & COMPANY

Booths A-52, B-39

Philip Morris & Company will demonstrate the method by which it was found that Philip Morris Cigarettes, in which diethylene glycol is used as the hygroscopic agent, are less irritating than other cigarettes. Their representatives will be happy to discuss researches on this subject and problems on the physiological effects of smoking.

PICKER X-RAY CORPORATION

Booths A-124, A-126, A-128, A-130

The Picker X-Ray Corporation will exhibit the Series '200' motor drive tilt table equipped with a spot film device; the Fully Automatic Electronic V-7 Vertical Control; a 100 MA motor drive Century unit; new type 15 MA Mobile unit; a complete line of accessory items including the new ANHYDRATOR for drying films without heat; the underwriter-approved EXPLOSION-PROOF ILLUMINATOR; and the new Weisman GYNOGRAPH.

THE GEORGE P. PILLING & SON CO.

Booths B-59, B-61

The Pilling exhibit will offer an extensive line of fine surgical instruments, both for general use and for many specialized applications. Bronchoesophagologists will be especially interested in the new Broncalloy instruments, made in Pilling's outstanding new stainless metal, developed especially for the bronchoscopic field. Many new instruments for use in otorhinolaryngology, thoracic surgery, and other special fields will also be exhibited.

PITMAN-MOORE CO.

Booth B-92

Among other products, Pitman-Moore will feature the dosage form of sulfadiazine most recently accepted by the Council on Pharmacy and Chemistry. Known as Magmoid Sulfadiazine, this is a smooth, creamy, orange-flavored liquid, containing in each average teaspoonful 0.5 Gm. (7.7 grs.) of sulfadiazine. Also featured will be the new Ultraviolet Irradiation Killed Rabies Vaccine, a product of considerably more potency than vaccines killed by ordinary methods.

PREMO PHARMACEUTICAL LABORATORIES, INC.

Booth A-57

W. F. PRIOR COMPANY

Booth A-19

Of special interest at the Prior exhibit will be their LOOSE-LEAF Publications: Tice's MEDICINE, Lewis-Walter's SURGERY, Brennemann-McQuarrie PEDIATRICS, and Davis' GYNECOLOGY AND OBSTETRICS. During 1947 approximately 2000 New and Revised pages of these reference works were sent to subscribers to bring them up-to-date. In 1948 several hundred new pages will be furnished to owners of these sets, including an entirely new volume for Tice's Medicine on Gastrointestinal Diseases.

THE PROCTER & GAMBLE COMPANY

Booths B-81, B-83

The Procter and Gamble Company will offer four time-saving leaflet pads for doctors: "Instructions For Routine Care of Acne," "Instructions For Bathing a Patient in Bed," "Instructions For Bathing Your Baby," and "The Hygiene of Pregnancy" all designed to answer patients' questions on routine care.

PROFESSIONAL BUDGET PLAN

Booth A-49

PROFESSIONAL EQUIPMENT COMPANY

Booth A-116

The exhibit of the Professional Equipment Company will feature the first showing of a new Vertical Fluoroscopy Attachment recently developed for the Profexray Table Combination Radiographic and Fluoroscopic Unit. This attachment synchronizes the travel of the screen and powerhead, both vertically and horizontally, with the patient standing or seated at the end of the table. Other Profexray Units which will be exhibited include the Vertical Combination, the Mobile and Portable Units.

THE PROMETHEUS ELECTRIC CORP.

Booth B-142

PURITAN COMPRESSED GAS CORP.

Booth C-60

Puritan Compressed Gas Corporation will be represented with a completely new convention exhibit featuring, among their full line of medical gases and gas therapy equipment, a display of authentic photographs showing actual installations of some of the latest PURITAN equipment. Representatives will welcome your visit.

THE PYRAMID RUBBER COMPANY

Booth A-155

By means of a new device that simulates actual nursing, the Evenflo exhibit will show how the air pressure *in the Evenflo Nurser is kept constant.* The air, admitted thru the pin hole valves in the Evenflo Nipple, bubbles thru the formula to relieve the vacuum as the milk is withdrawn. By adjusting the Evenflo Cap the rate of flow is altered to suit the individual infant.

RADIUM CHEMICAL COMPANY, INC.

Booth C-45

Facts about Radium and Radon Applicators and Accessories for the treatment of cancer and allied diseases will be given here. In addition to their complete line, the NEW MONEL RADIUM APPLICATOR, designed by the Radium Chemical Company, Inc. in accordance with specifications of otologists, will also be displayed.

THE RADIUM EMANATION CORPORATION

Booth A-82

The Radium Emanation Corporation will exhibit a wide variety of instruments and applicators used in modern Radium Therapy, including permanent and removable LEAK-PROOF radon seeds. A well-informed representative will be available to explain the equipment and its usage.

RARE CHEMICALS, INC.

Booths C-159, C-161

Male hormone preparations--Testosterone Propionate "Rare" for parenteral use and Methyl Testosterone "Rare" for oral use--will be the main feature of this exhibit. Other products to be included: Dienestrol "Rare" (new synthetic estrogen), Acidolate (liquid detergent), Dermolate (cake detergent), Gitalin (cardiac glycoside), and Salysal (salicylate which requires no alkali).

RAYTHEON MANUFACTURING COMPANY

Booth C-142

Latest console and portable *models* of the Microtherm, a microwave (radar) diathermy generator, will be exhibited. This equipment, the result of advanced technical research, provides a new medical tool. Microwaves and their special characteristics which make them particularly suitable for deep heating of the human body will be explained; and the new techniques of microwave therapy, demonstrated.

REED AND CARNRICK

Booth B-48

The Reed & Carnrick Institute for Medical Research will have an interesting display of Estrogenic Substances, R & C; Meprane Dipropionate (brand of Promethestrol dipropionate); orally potent synthetic *estrogen; and Solution Thiamine Hydro*chloride, R & C.

REXAIR DIVISION

Booth B-76

RITTER COMPANY, INC.

Booths A-110, A-112

WILLIAM H. RORER, INC.

Booth C-166

Carfusin "Rorer," Council-Accepted brand of Carbol-Fuchsin Paint, also known as Castellani's Paint will be the focal point of attention in Rorer's exhibit. The successful treatment of "Athletes Foot" and other fungus infections with Carfusin "Rorer" will be particularly *featured. Various* other Council-Accepted Rorer products, including Mannitol Hexanitrate, Diethylstilbestrol, Thiouracil, and other modern therapeutic aids, *will* be displayed.

ROYAL METAL MANUFACTURING CO.

Booth C-132

The very latest in reception room furniture will be shown by Royal Metal Manufacturing Company, makers of Royalchrome Furniture. Royalchrome will stress the fact that *you can completely* furnish your office with correlated furniture of the same type and beauty.

SAFETY GAS MACHINE CO., INC.

Booth A-12

SANBORN COMPANY

Booth B-21

SANDOZ CHEMICAL WORKS, INC.

Booths B-160, B-162

W.B. SAUNDERS COMPANY

Booths B-2, B-4, B-6

SCHENLEY LABORATORIES, INC.

Booth B-22

Penicillin will highlight the Schenley Laboratories, Inc. exhibit. *Their comprehensive line of* Penicillin products including Penicillin Tablets, Penicillin Troches, Penicillin Ointment, Penicillin Ophthalmic Ointment, etc., will be featured; and well-informed *personnel will be in attendance.*

SCHERING CORPORATION

Booth A-39

Schering Corporation, the world's largest manufacturer of hormones, will feature Estinyl (ethinyl estradiol) the most potent oral estrogen in clinical use today. Neo-Iopax, a safe urographic radiopaque medium, and Priodax, a standard cholecystographic medium will also be displayed. *Members of the Medical and Professional Service* Staffs of Schering will be present to welcome *inquiries on these important Council-Accepted* Preparations.

SCHIEFFELIN & CO.

Booth C-77

Schieffelin BENZESTROL, a non-stilbene synthetic estrogen developed in the research laboratories of Schieffelin & Co. will be featured. A qualified staff will be in attendance to explain the advantages of this product, and to answer questions with regard to other Schieffelin specialties.

JULIUS SCHMID, INC.

Booth C-116

Here physicians may view reproductions in color showing how, after examination of the patient, their prescription for the correct size RAMSES' Prescription Packet #501 will supply the patient optimum protection with simplicity in use. Representatives will be on hand to answer questions regarding RAMSES Flexible Cushioned Diaphragm, RAMSES *Diaphragm Introducer,* RAMSES *Vaginal Jelly,* RAMSES Vaginal Applicator, and RAMSES Fitting Rings.

G. D. SEARLE & CO.

Booths A-56, B-57

At the Searle booths a large number of anatomic and pathologic subjects will be exhibited in colored translites, colored slides, and plastic models. They will illustrate such various *conditions as conjestive heart failure, bronchial* asthma, hay fever, colitis, amebiasis, active rheumatoid arthritis, etc. Featured products of Searle Research will be Aminophyllin, Metamucil, Diodoquin, and Gold Sodium Thiosulfate.

SHAMPAINE COMPANY

Booths A-176, A-178

The Shampaine exhibit will feature the Perfection Major Operating Table, which is completely head-*end controlled; the famous Martin All-Purpose Chair-*Table; and a complete line of physicians' steel furniture, as well as upholstered reception room furniture. Factory trained representatives will be in attendance to discuss equipment problems with the doctors.

SHARP & DOHME, INC.

Booths C-69, C-71, C-73

Items of special interest at this exhibit include Blood Group Specific Substances A and B for conditioning group O blood to neutralize the anti-A and anti-B isoagglutinins; a new *dosage of 'Delvinal' Sodium Vinbarbital for* the production of obstetric amnesia and analgesia, 'Cresatin' Ointment for the treatment of common mycotic skin infections; and new antibiotic preparations including Tyrothricin along with 'Sulfathalidine' and 'Sulfasuxidine', intestinal bacteriostatic agents.

SHAY MEDICAL AGENCY

Booth B-23

*For those interested in securing better appoint*ments or seeking a different location, the Shay Medical Agency will have available a list of openings in Industry, Private Practice, Group Clinics, Public Health Organizations, Hospitals and Institutions, Universities and Medical Schools. You are invited to avail yourself of their services and to consult with them on problems of personnel.

THE SHEPARD ELEVATOR COMPANY

Booth B-178

In the Shepard Elevator exhibit may be seen *a novel demonstration of an actual* full-size HomeLIFT Residence Elevator in operation. Visitors will have the opportunity of riding in the HomeLIFT from floor to floor of the two-story exhibit.

SIEBRANDT MFG. CO.

Booths B-64, B-123

J. SKLAR MANUFACTURING CO.

Booth B-140

The Sklar exhibit will present an impressive display of new and standard Stainless Steel Surgical Instruments, many of which have never before been shown at an A.M.A. Convention. The display will also include *Sklar's full line* of Suction and Pressure Apparatus, Sklar's Improved Schiotz Tonometer, and the famous Davidson's Pneumothorax Apparatus.

CARROLL DUNHAM SMITH PHARMACAL CO.

Booth C-58

THE SMITH-DORSEY COMPANY

Booth C-54

SMITH, KLINE AND FRENCH LABORATORIES

Booths C-27, C-29

C. M. SORENSEN CO., INC.

Booth A-7

THE SOUNDSCRIBER CORPORATION

Booth C-184

Right next to the ever popular Physicians Art *Exhibit, The SoundScriber* Corporation will display SoundScriber electronic disc dictating equipment. This smart display will feature in large photographic treatment, some of the many and varied medical uses for SoundScriber. Doctors may actually dictate to this plastic disc equipment and see, by actual experience, just how it serves the medical profession.

SPENCER, INCORPORATED

Booth C-19

Spencer Individually Designed Supports prescribed by physicians in conservative and post operative treatment of ruptured intervertebral disc, sacroiliac and lumbosacral sprain, visce*roptosis, hernia and other conditions* will be featured. The Spencerflex for Men -a revolutionary and functional support design--will be of especial interest as will be the Spencer Breast Forms and the new adjuvant to thoracic surgery--the Spencer Thoracoplasty Binder.

SPINDLER AND SAUPPE

Booth A-157

THE SPIRELLA CO., INC.

Booths C-124, C-126

Spirella will show how their Foundation Garments use an entirely new and different method of corsetry designing. The unique Spirella method includes the use of exclusive modeling *Garments* which are adjusted to the patient to give just the degree of support desired. Then measurements are taken of the supported figure, and the patient's Spirella is individually made to exact specifications.

E. R. SQUIBB & SONS

Booth-139

With R.C.A., E. R. Squibb & Sons is sponsoring the *television program* being put on by Northwestern University Medical School. In booth B-139, E. R. Squibb & Sons is also presenting an exhibit on STREPTOMYCIN. A *series of colored slides* on current clinical problems in the use of this drug will be shown in continuous projection on a screen centered in the booth. Stress is *laid on* two important points: Action of Streptomycin on the eighth nerve, and the development of resistance.

STANDARD X-RAY COMPANY

Booth B-171

In Booth B-171 the Standard X-Ray Company will exhibit modern x-ray apparatus, especially designed for office installation. Attendants will be glad to furnish complete information *and recommendations* for individual requirements.

STEPHENSON CORPORATION

Booth C-90

R. J. STRASENBURGH COMPANY

Booth A-159

Anemias and the position of Folic Acid therapy in their management will be featured. Panels depicting the development and background of other Council-Accepted products will also be displayed. Capable representatives, including members of Strasenburgh's Research Staff, will be present at all times.

STRONG COBB AND COMPANY, *INC.*

Booth C-156 (East ½)

SURGERY, GYNECOLOGY AND OBSTETRICS

Booth A-6

The character, personality and quality of the journal "Edited by Practicing Surgeons to Meet the Needs of the Practicing Surgeon" *is depicted* at booth A-6. The printing, Illustrations, and editorial standard are portrayed through "Translites" which illustrate briefly the many features of America's foremost surgical journal.

SWIFT & COMPANY

Booths B-26, B-28

TAMPAX INCORPORATED

Booth A-59

Hygienic and comfortable protection afforded *in the* TAMPAX *method* of menstrual care and the importance of professional instruction of patients in the correct use of intra-vaginal tampons will highlight this exhibit. Educational consultants will share with you informal problems about which women have expressed need for guidance. New anatomical charts showing the female reproductive organs, prepared under the supervision of Robert L. Dickinson, M.D., will be available.

TAYLOR INSTRUMENT COMPANIES

Booths C-129

W. A. TAYLOR & COMPANY

Booth C-150

Diagnostic aids in the analysis of blood and urine will highlight the W. A. Taylor exhibit. Colorimetric equipment for determining sulfa drugs, blood sugar, NPN, urea nitrogen, urine pH, thiocyanate, icterus index, hemoglobin, cholesterol and PSP, supplied with guaranteed permanent color standards mounted by sets for each determination in plastic slides, and apparatus for determining blood chlorides and vitamin deficiencies will also be available.

THE TECHNICON COMPANY

Booths A-1, A-3

The AUTOTECHNICON which provides automatic tissue processing and staining by any preferred histologic technique; will be the SCOPICON which offers a most powerful light source for photomicrography or microprojection, either on wall screen, or in a dark-chamber table for small-group study; and the Technicon FRACTION COLLECTOR for automatic collection of fractional constituents in biochemical solutions.

TELEX, INC.

Booth C-172

TEXAS PHARMACAL COMPANY

Booth C-52

The Texas Pharmacal Company will exhibit a complete line of hypo-allergenic cosmetics, marketed under the name of Allercreme, also bases and vehicles for use in preparing dermatological prescriptions.

CHARLES C THOMAS PUBLISHER

Booth C-2

MARVIN R. THOMPSON, INC.

Booths C-162, C-164

THE TOIDEY COMPANY

Booth B-176

Pediatricians and other physicians who care for children, will want to call at booth B-176, near the Art Exhibit, to see the new Toidey Specimen Collector, helpful in getting specimens for urinalysis from both the infant and the growing toddler. Special complimentary discounts will be given physicians on orders for Little Toidey and allied items, including comfySAFE AutoSeat.

THE TOWER COMPANY, INC.

Booth B-130

U.M.A. INC.

Booth B-24

PERIPHERAL VASCULAR DISEASES will headline the U. M. A. exhibit. Here you will see the COLLENS Sphygmo-oscillometer, a blood pressure apparatus and oscillometer combined in one instrument, for the diagnosis of Vascular Disease; and the COLLWIL Intermittent Venous Occlusion Apparatus, for the therapy of Vascular Diseases.

UNIVERSAL PRODUCTS CORP.

Booth B-120

UNIVERSAL X-RAY PRODUCTS, INC

Booth C-176

THE UNIVERSITY OF CHICAGO PRESS

Booth C-24

Distinguished for authoritative content and excellence of editorial work, the books of University Presses claim enviable rank among non-fiction and technical publications. The Association of American University Presses has arranged a cooperative exhibit for your enjoyment at this meeting--and to give you an opportunity to purchase some of the important titles for your library.

THE UPJOHN COMPANY

Booths B-116, B-118

The theme of The Upjohn Company exhibit will be "Adrenal Cortex and Resistance." The central panel of the exhibit symbolizes that man's resistance to stress is being increased by science. The other panels show the effect on the adrenals of various stresses -- infection, exercise, surgery, and anoxia. The final panel shows the relative potency of adrenal cortex sterile solution and lipo-adrenal cortex steril solution

U.S. VITAMIN CORPORATION

Booth C-7

THE VANTA COMPANY

Booths C-76, C-78

VANTA garments for infants -- layette items without pins or buttons and Self-Help garments for Toddlers will be exhibited in Booths C-76, C-78 Vanta, originator of the Tie Vest, Sun Suit, K-Band Baby Bess Hose, and other important features, will also show No-Fas-Ning shirts and the latest developments in proper clothing.

VARICK PHARMACAL CO. INC.

Booths C-81, C-83

VICTOR PRODUCTS CORPORATION

Booth A-109

WALGREEN DRUG COMPANY

Booth A-137

One of America's most modern Prescription Departments as developed by Walgreen Drug Company for future installation in its stores will be seen here. Complete in every respect, this new unit will go into service in a new Walgreen Drug Store when the Convention is over. Your full inspection is invited. Walgreen Registered Pharmacists in attendance will be happy to hear your comments.

WALKER VITAMIN PRODUCTS, INC.

Booth B-104

Walker will again exhibit its line of Council-Accepted vitamin tablets, capsules, injectable solutions, and pediatric drop preparations. Experienced representatives in attendance will be qualified to discuss all phases of vitamin therapy.

WALLACE LABORATORIES, INC.

Booth B-3

WALLACE & TIERNAN PRODUCTS, INC.

Booth C-177

WALTON LABORATORIES, INCORPORATED

Booths A-61, A-63, A-65

Shown for the first time at an A.M.A. Annual Session will be the newly developed Oxygen Tent Humidifier of Walton Laboratories, Inc. This unit makes it possible to maintain a high humidity in an oxygen tent while oxygen is being administered. Other humidifiers of interest will include Pottery and Bronze table models; single and duplicate cabinets, and a highboy Model.

THE WANDER COMPANY

Booth A-87

Visitors are invited to stop at the Wander Company booth for a drink of delicious Ovaltine. Attendants will gladly answer any questions you may have about the composition, merits, and usefulness of Ovaltine. Valuable, informative literature on nutrition will also be available for distribution.

WILLIAM R. WARNER AND CO., INC.

Booths B-82, B-84

WATERS CONLEY COMPANY

Booth C-8

A new Automatic Home Pasteurizer which offers safe, pasteurized milk to every farm family in rural areas where commercially pasteurized milk is unavailable will be displayed at the Waters Conley exhibit. Also featured will be some of the excellent scientific instruments made by the Waters Conley laboratories, including the Cardiotachometer and the Kymographic Camera.

WECO PRODUCTS COMPANY

Booth C-140

This attractive exhibit will be devoted to Dr West's Miracle-Tuft Toothbrushes. Combining exaggerated size, color, and illumination, Dr. West's have reproduced a giant Miracle-Tuft Toothbrush and its well-known glass package. Lithographed in full color on transparent parchment and shaped like the actual glass package, it makes a pleasing and powerful reminder to the layman to replace his Dr. West's Miracle-Tuft Toothbrush.

WELCH ALLYN, INC.

Booth B-5

Visitors to the Welch Allyn exhibit will find a wide variety of diagnostic instruments -- the ophthalmoscope, otoscope, rectal instruments, transformers, and laryngoscopes. Educational slides, photographs, and paintings will assist the doctor in the more efficient uses of diagnostic instruments.

THE WESTERN ELECTRIC COMPANY

Booth A-174

Western Electric's 4-Type Group Audiometer for testing the hearing of as many as forty persons at a time, as well as the 6-Type Audiometer for individual hearing tests, will be shown here. In addition, Western Electric's new Models 65 and 66 Hearing Aids will be demonstrated. Visitors to this exhibit will also have an opportunity to review important new developments of Bell Telephone Laboratories.

WESTINGHOUSE ELECTRIC CORP.

Booths A-36, A-38, B-35, B-37

Four major units will be exhibited by Westinghouse X-Ray Division; the DUOFLEX Table with the new 4 on 1 Spot Film Device and Reciprocating Bucky; the MONOFLEX-a single tube diagnostic unit; the RX-a single tube unit designed especially for the general practitioner and small hospital; and the PFX - the mass chest x-ray unit. In addition, various models of automatic controls will be displayed.

WHIRLPOOL CARRIAGE, INC.

Booth C-28

WHITE LABORATORIES, INC.

Booths B-69, B-71, B-94, C-15, C-17, C-94, C-95

THE WILLIAMS AND WILKINS COMPANY

Booths C-10, C-12

Convention visitors are cordially invited to visit the brand new exhibit of The Williams & Wilkins Company. It will reflect modern design and present new features never before used by a medical publisher, including a built-in slide-projection apparatus. More than 20 new 1948 books will be displayed.

·WINTHROP-STEARNS INC.

Booths C-47, C-49, C-51, C-53

Winthrop-Stearns Inc.—new owner of the businesses formerly conducted by Winthrop Chemical Co. and Frederick Stearns & Co.-will feature transparencies of beautiful medical art by the well-known artist, Mr. Leon Schlossberg. The exhibit includes (1) kidney and renal pelvis and calices; (2) head with paranasal cavities; (3) section through woman at term; (4) cardiovascular failure and edema; (5) normal heart with valves; (6) brain, including visualization of the thalamus, hypothalamus, and medulla oblongatha; (7) normal bone marrow; (8) pathogenesis of hypertension.

WISCONSIN ALUMNI RESEARCH FOUNDATION

Booth B-60

The Foundation will show by charts the results of recent studies with the anticoagulant Dicumarol and with diluted plasma determinations. It will also show the effect of other substances on prothrombin. Christian P. Segard, M. D., Medical Director of the Foundation will be at the booth.

THE MAX WOCHER AND SON CO.

Booth C-93

WOODWARD MEDICAL PERSONNEL BUREAU

Booth B-7

Woodward Medical Personnel Bureau, with a record of 52 years of continuous service to the profession will offer its facilities in Booth B-7. Credentials of really outstanding medical personnel seeking appointments and unusual openings for qualified men in all specialties will be available. Physicians, hospital managers, and other executives will want to stop by for a discussion of their personnel problems.

WYETH INCORPORATED

Booths B-66, B-68, B-70, B-72

THE YEAR BOOK PUBLISHERS, INC.

Booth C-9

F. E. YOUNG AND COMPANY

Booth A-129

ZENITH RADIO CORPORATION

Booth A-167

On display here will be the new Zenith '75' Hearing Aid -- the radionic instrument formally announced to the profession in the J.A.M.A. of February 28, 1948. Zenith representatives will be pleased to explain a plan whereby the '75' can be tested by any physician without cost or obligation to him or his hard-of-hearing patients.

ZIMMER MANUFACTURING COMPANY

Booth B-113

In addition to a complete line of splints and all types of fracture equipment, Zimmer will display new and improved instruments including the Moreira Stud-Bolt, Myerding Chisels-Gouges-Osteotomes, Bone Clamps, Doctor Eggers Contact Splint, Bone Plates and Cross Slotted Screws, Two-Speed Hand Drill, Intramedullary Nails & Instruments, Scott-McCracken Periosteal Elevators, Blount Staple Set, and the Luck Bone Saw.

ORGANIZATION SECTION

JOINT COMMITTEE FOR THE COORDINATION OF MEDICAL ACTIVITIES

Report of Meeting in Chicago, March 6, 1948

The Joint Committee for the Coordination of Medical Activities met in the Board Room of the American Medical Association Building in Chicago, Saturday, March 6, 1948. The meeting was called to order by the Chairman, Dr. Ernest E. Irons. Members, liaison members and guests present included:

Dr. Donald G. Anderson
Brig. Gen. George E. Armstrong
Dr. Walter L. Bierring
Dr. Frederick A. Coller
Mr. P. H. Costello
Dr. W. Palmer Dearing
Dr. Warren F. Draper
Capt. William E. Eaton (MC), U.S.N.
Dr. Morris Fishbein
Father John P. Flanagan, S.J.
Dr. J. F. Hammond
Dr. Elmer L. Henderson
Mr. Thomas A. Hendricks
Dr. Ernest E. Irons
Dr. George F. Lull
Capt. F. L. McDaniel (MC), U.S.N.
Dr. J. J. Moore
Dr. H. B. Mulholland
Dr. Walter L. Palmer
Dr. James E. Paullin
Col. Paul I. Robinson
Dr. R. L. Sensenich
Dr. E. R. Serles
Miss Mary Switzer
Mr. Kenneth Williamson

The Surgeon General of the Navy requested that the Medical Department of the Navy should have two representatives, so Captain Eaton will continue his connection with the Joint Committee and Captain McDaniel will represent the Bureau of Medicine and Surgery. Mr. P. H. Costello, secretary of the National Association of Boards of Pharmacy, was in attendance in place of Dr. Fischelis, representing the American Pharmaceutical Association.

NAVY MEDICAL TRAINING PROGRAM IN PACIFIC

Captain McDaniel read the following memorandum, signed by Robert V. Schultz, Commander (MC):

> The School of Medical Practitioners, Guam, shortly will be designated officially by the Navy as the School of Medical Assistants, Guam, in conformity with the recommendations of the Committee appointed at the Dec. 6, 1947 meeting of the Joint Committee for the Coordination of Medical Activities.

(The Committee mentioned by Commander Schultz consisted of Dr. Edward L. Bortz, President, and Dr. George F. Lull, Secretary of the American Medical Association, and Commander Schultz.) The Joint Committee expressed satisfaction with the proposed designation of the Guam school as reported by Commander Schultz.

THE GENERAL PRACTITIONER

Dr. Sensenich, member of the Subcommittee on the General Practitioner, presented information relative to a recent meeting of the Board of Trustees of the American Medical Association with officers and representatives of the American Academy of General Practice, which was organized at Atlantic City, N. J., in June 1947.

> The general practitioner is defined as "a licensed physician and surgeon who holds the degree of M.D., and who does not limit his practice exclusively to a particular field of medicine or surgery."
>
> The objects and purposes of the academy are: (1) to promote and maintain high standards of the general practice of medicine and surgery; (2) to encourage and assist young men and women in preparing, qualifying and establishing themselves in general practice; (3) to preserve the right of the general practitioner to engage in medical and surgical procedures for which he is qualified by training and experience; (4) to assist in providing postgraduate study courses for general practitioners, and to encourage and assist practicing physicians and surgeons in such training, and (5) to advance medical science and private and public health.
>
> Does the academy advocate that all general practitioners be permitted to practice medicine and perform surgery in all hospitals? No. The academy recommends that proper requirements be maintained for staff privileges in all hospitals; ... that hospital privileges be extended to all licensed physicians on the basis of competency. ... The academy endorses official actions taken by the American Medical Association, the American Board of Surgery and other interested organizations opposing any hospital regulations which confine staff membership or the right to perform certain medical and surgical procedures to specialists who have been certified by the respective specialist boards.
>
> Does the academy propose to establish a certifying board in general practice? No. In years to come a certifying board of general practitioners to examine candidates engaged in general practice may be feasible, but such is not the present intention of the academy. While the academy does not plan to conduct examinations of candidates for membership, membership for the general practitioner in the academy corresponds to a certification by a board for the specialist.
>
> There are approximately 135,000 members of the American Medical Association. Of these, approximately 40,000 are specialists. Thus there are nearly 100,000 general practitioners. It is hoped that eventually most of these will become affiliated with the American Academy of General Practice.

Dr. Bierring, also a member of the Subcommittee, discussed the subject. He observed that there is at least a tendency to feel that within the next ten years the practice of medicine and the offices of physicians will center more and more around a hospital, and that there will be a closer integration. He said: I feel that by establishing a special service for general medicine in a large general hospital, the participants will appreciate what a broad field they have before them for service to their patients and will feel that it is a better opportunity for them than if they confine themselves to some special field where they will be limited in their practice and limited, also, with respect to locations.

Dr. Fishbein stated that the Colorado experiment is only one of about thirty experiments now being made, and that he thought it would be a mistake to endorse any one of these experiments as ideal. He also thought that all of them should be watched and ought not to be discouraged. Dr. Fishbein continued: One thing which has been forgotten in these experimental plans is the great significance of the cost of transporting patients, which in many instances amounts to more than the entire medical bill.

It was the opinion of the Chairman that the Joint Committee for the Coordination of Medical Activities might "view with interest" all these experiments, and that out of them should come improvement in medical education and medical practice.

Dr. Anderson said: There is apparently a definite increase in the feeling of responsibility on the part of medical schools to interest and stimulate their students toward general practice. There is also apparently a definite increase of interest on the part of the students themselves. Several polls taken during the last year indicate that there is a reversal of the feeling of two to four years ago, when the great majority of students indicated desire to go into special fields of practice. I think that no less than forty to forty-five of the medical schools have some definite program under way to interest the students in this type of practice on the undergraduate level and some on the graduate level.

BIPARTISAN COMMITTEE ON REORGANIZATION OF FEDERAL AGENCIES

Miss Switzer submitted a report on the status of the Bipartisan Committee on Reorganization of Federal Agencies, of which Mr. Herbert Hoover is chairman.

NATIONAL HEALTH ASSEMBLY

The Chairman requested a discussion of the plans and purposes of the National Health Assembly called by the Federal Security Administrator, Mr. Oscar R. Ewing, to meet in Washington, D.C.

COOPERATIVE HEALTH EDUCATION PROGRAMS

Dr. Serles read a report prepared by Dr. Robert P. Fischelis, of the American Pharmaceutical Association, relative to encouraging the utilization of the pharmacies of the United States in the education of the public on health matters.

Each year the American Pharmaceutical Association would dedicate National Pharmacy Week to one of the broad public health programs. This year more than seventeen thousand pharmacies have responded, and difficulty in financing the supply of a sufficient number of displays to meet all requests is experienced.

In addition to the aid given the American Cancer Society through National Pharmacy Week, special assistance was provided the American Heart Association this year in its campaign to present forcefully to the attention of the public the necessity for early recognition and treatment of cardiovascular diseases. Thousands of displays were asked for by pharmacists, at the suggestion of the American Pharmaceutical Association, through a special bulletin issued to the members of State Pharmaceutical Associations.

Dr. Fishbein thought the material which the American Pharmaceutical Association is distributing for display in individual pharmacies represents a commendable effort in public health education supplementing that of medical schools and medical agencies. He moved that the Joint Committee for the Coordination of Medical Activities endorse it as a part of the great campaign for public education.

UNIFORM PHARMACY PRACTICE ACT

Dr. Serles presented a statement concerning the need for greater uniformity of the laws governing the practice of pharmacy in the several states.

The educational requirements and the procedure for licensure have attained a high degree of uniformity. The actual practice of the profession in the several states varies considerably. This affects not only the procedures followed by the pharmacist, but it likewise affects the practitioner of medicine and is ultimately reflected in the service to the patient. In only one instance of prescription practice are the procedures generally quite uniform, and that is the distribution of drugs under the Harrison Narcotic Act. In all other instances the establishment of the practice of pharmacy under the state pharmacy practice act has resulted in a wide variance of procedure for such important drugs as the barbiturates, the dangerous drugs, drugs not requiring a prescription, drugs dispensed by a physician, drugs dispensed in hospitals, drugs distributed by state boards of health and drugs distributed by mail order houses.

Dr. Serles read the proposed uniform pharmacy practice act and asked the support of the Joint Committee, saying that the American Pharmaceutical Association is desirous of securing the strongest support from all interested agencies. The Chairman wondered if the proposed law might not be so extensive that it could be attacked on the ground that it created a monopoly, and Dr. Serles replied that he thought not, that it has been carefully studied by the National Drug Trade Conference and that in the major part it simply defines the practice of pharmacy.

Dr. Fishbein moved that the Joint Committee for the Coordination of Medical Activities endorse the principle of a minimum standard and its uniform adoption throughout the nation for the practice of pharmacy under laws and regulations that will protect both the people and the pharmacist. The motion was seconded by Dr. Bierring and was adopted.

HOSPITAL SURVEY AND CONSTRUCTION ACT

Dr. Dearing reported that the House of Representatives has passed a deficiency appropriation of several million dollars. Thirty-six state plans covering three fourths of the states have now been approved. The total cost to the government is $63,000,000. One hundred and fifty individual projects have been approved, totaling $69,000,000 worth of construction. Two thirds of the money involved is nonfederal, one third federal. Presumably construction has actually started on some projects. It is possible that changes in the basic act to provide additional appropriation will be considered near the end of the period which the act covers. Congress has shown no disposition to hold back on the allocation as the projects have come in; the deficiency appropriation for this year is an indication of the trend.

OSTEOPATHS AND THE GOVERNMENT SERVICES

The Chairman asked Dr. Dearing to give the Joint Committee some information about the recent amendment of the Public Health Service Act, and Dr. Dearing replied as follows:

> Our so-called promotion bill to amend the Public Health Service Act was for the purpose of putting the promotion system in line with that of the armed services. An amendment was added, which we did not sponsor or request, which provides that "graduates of colleges of osteopathy whose graduates are eligible for licensure to practice medicine or osteopathy in a majority of the States of the United States, or approved by a body or bodies acceptable to the Administrator, shall be eligible subject to the other provisions of this Act, for appointment as commissioned medical officers in the Public Health Service."
>
> Much thought has been given to this problem. The basic law covering the Veterans Administration authorizes the appointment of osteopaths, and the Navy also has authorization for the appointment of osteopaths as medical officers, but there are certain limitations. Under this amendment, the Public Health Service has no such limitations. The utilization of the osteopaths, if they pass the examinations and are admitted, will be somewhat of a

> problem; two or three of our hospitals have indicated that they could use a properly trained man in the physical medicine departments. The Veterans Administration has one and is about to or just has employed another.

A motion was made by Dr. Fishbein that the Joint Committee for the Coordination of Medical Activities " view with alarm " the possibility of commissioning as medical officers in the U. S. Public Health Service persons without adequate knowledge or training in preventive medicine and public health. The motion was duly seconded and adopted.

OUTBREAKS OF ILLNESS AMONG THE NEWBORN IN HOSPITALS

Mr. Williamson was asked by the Chairman to present a brief statement on outbreaks of illness among the newborn in hospitals, a subject on which Mr. Graham Davis had requested discussion at the last meeting of the Joint Committee. Mr. Williamson's remarks were as follows:

> One approach that is being made to the problem is a basic study of the formula room, and it is expected that the committee having this in hand will make a report by September. Some radical changes probably will result from this study and improvements will ensue, probably in the simple things like the washing of bottles, and the space used.

IMPROVEMENT OF SURGICAL SERVICE IN HOSPITALS

The Chairman asked Dr. Fishbein to speak on the subject of improvement of surgical service in hospitals, which he did as follows:

> We have been working for some time on a proposal that there be published annually in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION a tabulation of the number and character of surgical operations and their general results. In the initial study, probably one hundred hospitals will be chosen at random and asked to keep records over a six month period of at least two surgical operations. The hospitals and the surgeons doing operations will be coded and the whole study carried out on an anonymous basis. If adequately conducted, the study should bring out a vast amount of important and controlled information as to the quality and the results of surgery in the hospitals over the country. It is conceivable that a study of this kind would result in a great improvement of surgical service and also might help to refute charges of unnecessary surgical procedures.

Dr. Coller said that the American College of Surgeons has been discussing the same thing and already has carried on studies of a similar nature. Dr. Henderson thought the project extremely worth while and moved that the Joint Committee for the Coordination of Medical Activities endorse it. The motion was seconded and adopted.

AMERICAN RED CROSS BLOOD BANK PROGRAM

Dr. Draper presented a statement to the effect that the first national blood center had its official opening at Rochester, N. Y., on January 12. On the following day this center was serving all the hospitals in the city and also the hospitals in the cities in the eleven surrounding counties. This is known as the Genesee Valley National Blood Center, and supplies the blood needs of more than a million persons. The physicians and hospitals in this area are pleased, and the program has the complete cooperation of the medical societies and all other agencies concerned.

The second national blood center was opened at Wichita, Kan., on January 14. It is a going concern at the present time and is supplying the blood requirements of all of the hospitals in Wichita in a satisfactory manner. The regional program is being expanded throughout the seven surrounding counties. There is complete cooperation on the part of all of the medical societies, physicians and hospitals throughout the area, all having expressed entire satisfaction with the program.

The third national blood center was opened at Atlanta, Ga., on February 17, There are forty-one participating chapters of the Red Cross in the counties surrounding Atlanta extending for a radius of 80 miles. At present the program is supplying the hospitals in Atlanta and the mobile operation is well under way. When in full operation this program will meet the hospital needs in all cities within the area and will meet the blood requirements of approximately 1,500,000 persons.

The fourth national blood center was opened at Stockton, Calif., on February 21. It serves the northern end of the San Joaquin Valley and supplies the blood requirements of approximately 500,000 persons. There is complete cooperation on the part of the medical societies and hospitals within the area, and all have expressed great satisfaction with the results which are being obtained.

A blood center was opened at Washington, D. C., on January 9 on a limited basis. It will become a part of the national program about May 1. At present it is supplying the needs of the veterans' hospital and other government hospitals in the District of Columbia, and also emergency service in all hospitals in the District of Columbia.

The national blood center at Louisville, Ky., is in the process of formation and will be in operation probably about May 15. It will serve the city of Louisville and fourteen surrounding counties in Kentucky and Indiana.

A national blood program center will be opened at San Jose, Calif., on May 1. It is being developed with the full cooperation of the local medical societies and all other agencies. It will supply the blood needs of more than 500,000 persons in the Santa Clara and Salinas Valleys and in Santa Cruz County.

The blood program of the state of Massachusetts became part of the National blood program on March 1. It serves the entire state of Massachusetts with the exception of Boston proper. A contract is in force with the state laboratories for the processing of blood collected from the various cities.

Dr. McIntire has held discussions with representatives of the Chicago Red Cross Chapter and its Medical Advisory Committee, with a view to starting a National Blood Program center in the autumn of this year.

After lengthy discussion, the Joint Committee voted to reaffirm its approval in principle of the Red Cross Blood Bank Program and authorized the earliest possible publication of the progress report presented by Dr. Draper.

RURAL MEDICAL SERVICE

Dr. Mulholland presented the following progress report:

> The third National Conference on Rural Health was held about a month ago. Preparation and planning for the Conference was participated in by the American Academy of Pediatrics, and the general theme of the program was the health status of the rural child. Also cooperating in the Conference were the National Cooperative Milk Producers Federation, the Farmers' Educational Cooperative Union, the National Grange and the American Farm Bureau Federation. More than five hundred persons were in attendance.
>
> One of the highlights of the Conference was the presentation by Dr. Maurice H. Friedman of his analysis of selective service statistics, in which

he shows that the draft rejectee figures are not a measure of the health of any community. We had at the Conference four young persons from rural areas who told us exactly what they thought about rural medical service and care. There was considerable discussion about nutrition, school lunches and child psychology. One of the main points brought out in the various papers and discussions was the need for more and better medical service in rural areas. Most of the efforts of the Committee on Rural Medical Service are in that direction, and we hope to have working for us a specialist who will be able to help the local people and show them how the needs can be met.

WORLD MEDICAL ASSOCIATION

Dr. Henderson presented a report on the present status of the World Medical Association.

A classification of Founder and Sustaining Member of the United States Committee has been established to include physicians, medical organizations allied to the medical profession, such as the American College of Surgeons and the American College of Physicians. The organizations will be requested to come in as Founder and Sustaining Members with a membership fee of $2,000 a year. The dues of the American Medical Association as a member of the World Medical Association probably will be more than double the dues of any other organization, the nearest being the British Medical Association. Most of the medical organizations of Europe are destitute and cannot supply funds. In addition to the dues paid to the World Medical Association, which are substantial, the American Medical Association has come in as a Founder and Sustaining Member of the United States Committee at $2,000 a year, and some other medical organizations have become Founder and Sustaining Members. Business firms serving or allied to the medical profession are asked to contribute to the United States Committee according to the size of their organizations. We have had quite a few contributions, ranging from $10,000 down to $100. Within the next few days we expect to send out a letter to a selected number of physicians over the country, about 10,000, requesting them to come in as Founder and Sustaining Members with a membership fee of $10 a year. There have been quite a number of physicians who have already come in and subscribed under that provision. Some laymen will join under the same category at $10 a year.

The delegation from the United States has reason to believe that the World Medical Association is a wholly worth while project. It is going to take money. The United States Committee has undertaken to pay all the expense of the headquarters office, which will be located in New York. In addition to paying all the expenses of the office and that involved in the publication of a bulletin or journal, we shall have to pay the expenses of the officers and Council members when they attend a meeting, which probably will be twice a year. It was voted in Paris, France, that the annual assembly this year would be held in Prague, Czechoslovakia, but since then there have been developments which may make it impossible to go to Prague. We are hoping that at the meeting of the Council in April the location for the assembly will be changed to some other country, and some of us hope it will be held in Geneva, Switzerland. Incidentally, checks in support of this enterprise can be made payable to the World Medical Association, United States Committee.

INFORMATIONAL REPORTS

Graduate Education for Medical Officers in the European Theater of Operations

The Chairman inquired of General Armstrong concerning the development of the educational plan for medical officers in European service, and the general stated that matters are going along in a most satisfactory manner and that the response of American physicians volunteering to spend a certain length of time in Europe for the purpose has been gratifying.

TIME AND PLACE OF NEXT MEETING

It was decided to hold the next meeting of the Joint Committee for the Coordination of Medical Activities at American Medical Association Headquarters in Chicago on Saturday, June 5, 1948.

Washington Letter

(From a Special Correspondent)

May 13, 1948.

Ewing Drafting Ten Year Health Plan for Nation

Federal Security Administrator Oscar R. Ewing announced that an outline of a ten year national health plan requested by President Truman last January would be ready within a few weeks. He made this announcement following the wind-up of the National Health Assembly here. He is studying the reports of the fourteen conference sections to obtain material for the program, but emphasized that he will take full responsibility for whatever plan is submitted to Mr. Truman. Mr. Ewing declared that the assembly had been " unbelievably successful." He said the exchange of opinions between lay and professional people would produce public opinion to support a health program.

Early Action on World Health Organization Expected

The House of Representatives is expected to take action soon on legislation to permit the United States to join the World Health Organization. Speaker of the House Joseph W. Martin Jr., Republican of Massachusetts, expressed the hope that the House Rules Committee, which has had the bill tied up for months, would report on the bill in the immediate future. Representative Leo Allen, Republican of Illinois, Rules Committee chairman, said that he knew of no change in the opinion of members who had tabled the measure early in March, but it was reported elsewhere that a sufficient number of members have swung over to assure passage. The State Department has favored early action so that the United States could take part in the meeting of the World Health Organization in Geneva, Switzerland, in June.

Federal Security Agency Voted Operating Funds

The House has voted and sent on to the Senate a bill appropriating $969,050,000 in operating funds for the Federal Security Agency for the fiscal year beginning May 1. The measure is $20,673,000 below the total requested by the agency for its activities, which include the U.S. Public Health Service and the Food and Drug Administration. The bill also provides $1,000,000 for a national campaign to train dentists in the use of sodium fluoride to check dental decay.

House Approves Bill for Research on Artificial Limbs

The House of Representatives has passed and sent to the Senate a bill to give the Veterans Administration $1,000,000 annually to continue its research on artificial limbs. Results of the studies would be available to public rehabilitation agencies as well as the Veterans Administration under the provisions of the bill.

Antitrust Suits Against Optical Dealers and Eye Doctors

Attorney General Tom Clark announced that he has filed four antitrust suits against a group of Midwestern optical wholesalers and a long list of eye doctors. The complaints allege that the companies turned over to the eye doctors about half of the fees charged patients for filling prescriptions for glasses. The suits seek to halt payment of such rebates or prevent their acceptance by doctors. Assistant Attorney General John F. Sonnett, head of antitrust prosecutions, said it was hoped that the actions would cut substantially the prices of eye glasses to the public.

ARMY

MORE RESERVE OFFICERS ON ACTIVE DUTY

The Surgeon General announced April 12 that authority had been granted to place three hundred medical service reserve officers on extended active duty. Reserve officers who volunteer may be assigned to duty in all four sections of the corps according to their qualifications. The greatest need is in the medical allied science section, which includes personnel trained in biochemistry, nutrition, physiology, serology and psychology.

The Regular Army Medical Service Corps has an authorized officer strength of one thousand and twenty-two. Vacancies in this corps will be filled through the medium of competitive tours of active duty for reserve officers. Qualified men interested in an Army career may apply for reserve commissions. Plans are being made to expand the graduate training program for Regular Army Medical Corps Officers, including training at civilian institutions in a wide variety of subjects. Many leading universities are cooperating in this training program.

The Surgeon General has announced that the following medical reserve officers have entered on tours of active duty with the Army: Colonels Charles Holmes, Seattle, and Norman W. Elton, Newton Highlands, Mass.; Lieut. Col. Henry C. Dorris, Winona, Miss.; Majors Lester S. Grieder, Dauphin, Pa., and Julian C. Kennedy, Indianapolis; Captains Timothy A. Callahan, Baltimore; William B. McLaughlin, West Orange, N.J.; Antonio S. Medinga, Box 177, Mato Rey, Puerto Rico; Charles Norman Moss, Boston; William Stone, San Pedro, Calif., and Ernest Allan Brav, Louisville, Ky., and Lieut. Harry Vernon Pifer Jr., New York.

DAYS LOST DUE TO SICKNESS AND INJURY

Lieut. Col. Alfred P. Thom, M.C., chief, Development Branch, Medical Research and Development Board, Office of the Surgeon General, Composite Group, Bridgeport and Hartford, Conn., March 10-11, said that: "During the last war, wounded, died of wounds, killed in action and prisoners of war were responsible for about one third of the permanent losses of effectives that occurred, the remainder being largely due to sickness and injury. About 15,000,000 men were hospitalized for disease between Jan. 1, 1942 and Aug. 31, 1945, and 2,000,000 men were hospitalized for injury. With manpower probably the most critical item in our war effort, it is estimated that the average loss of manpower through hospitalization and quarters amounted to an average of over 309,000 men per day throughout the war period, and that an additional 773,000 directly or indirectly were required for patient care. It is thus apparent that, with about 10,000,000 men mobilized by the Army, at least 1 out of 10 men was totally unavailable for tactical or other military employment, because of either being a patient, or through being required for patient care. This condition exists in spite of the best medical service probably ever possessed by an Army, and with the best health, disease and injury treatment record of any Army in History."

MEDICAL SERVICE IN CANAL ZONE

Members of the Committee on Medical and Hospital Services of the Armed Forces, appointed by the Secretary of Defense, recently visited the Panama Canal Zone. The members who went there are the Surgeon General of the Army, Major Gen. Raymond W. Bliss, the Surgeon General of the Navy, Rear Admiral Clifford A. Swanson, Col. John Hargreaves, M.C., representing the Air Surgeon, and Major Gen. Malcolm C. Grow, M.C. These representatives agreed on the approach to medical problems related to the Canal Zone. This area is unique in having an over-all medical problem affecting the Army, Navy, Air Force and Panama Canal organization. Medical services there can be coordinated for the best interests of all these elements. There is unanimity of purpose and action to demonstrate to the world that the highest health standards can be maintained in a tropical area. The Committee on Medical and Hospital Services is not empowered to take direct action and is obligated to make recommendations to the Secretary of Defense.

PERSONAL

Major Frank B. Rogers, M.C., has been appointed special assistant to the director of the Army Medical Library. Major Rogers graduated at Yale University and the Ohio State University Medical School and entered the military service in 1943. After serving in the Pacific area during the war and in Japan, he served briefly at Walter Reed General Hospital before coming to the library.

NAVY

NEW REGULAR OFFICERS

The following graduates of the Navy's V-12 program have accepted appointments in the medical corps of the regular Navy: Lieuts. (jg) John W. Howard, Argyle, N.Y.; Thomas W. Stewart, Pelham, N.Y.; Louis Sussman, New York; Albert E. Thielen, Cincinnati, and Richard K. Williams, Richmond, Va.

Comdrs. Warner D. Bundens Jr., Mickleton, N.J.; Broor A. Johnson, Rita, N. Mex., and Lieut. Comdr. John D. Boland, Sterling, Ill., of the naval reserve, have accepted appointments in the regular Navy Medical Corps.

The following physicians have accepted appointment in the medical corps of the Regular Navy: Lieut. (jg) Charles E. Boonstra, Lafayette, Ind., graduate of the University of Indiana School of Medicine under the V-12 program; Lieut. (jg) Robert E. Baker, Detroit, formerly medical corps reserve officer; Lieut. Ralph L. Vasa of Brooklyn, formerly in the reserve corps, and Lieut. (jg) Leonard J. Raider, Philadelphia, a graduate of the University of Pittsburgh School of Medicine.

PERSONALS

Capt. Eric G. Hakansson, commandant, Naval Medical Research Institute, Bethesda, Md., has been ordered to the Naval Hospital for treatment and has been relieved as commandant of the Research Institute by Capt. Charles F. Behrens, formerly chief of the Atomic Defense Division of the Bureau of Medicine and Surgery.

Rear Admiral J. C. Adams (MC) was recently honored by appointment to Honorary Commander of the Most Excellent Order of the British Empire in recognition of his contribution to the allied war effort while serving as chief of the Division of Aviation Medicine.

OFFICERS REQUEST POSTGRADUATE TRAINING

The advisory Board of the Bureau of Medicine and Surgery on March 24 approved the requests for postgraduate training of the following medical officers:

Capt. Charles L. Ferguson, Waynesville, N.C., course in internal medicine, University of Pennsylvania Graduate School of Medicine.
Capt. Edward S. Lowe, Long Beach, Calif., course in surgical anatomy, Cornell University Medical College.
Comdr. Peter J. Giotta, Bronx, N.Y., residency in ophthalmology, Naval Hospital, St. Albans, L.I., N.Y.
Comdr. Peter P. Machung, Manticoke, Pa., extension course of instruction in neurology, Jefferson Hospital, Philadelphia.
Comdr. Waite R. Griswold, Indianapolis, fellowship, Illinois Psychiatric Institute.
Comdr. William S. Baker Jr., Detroit, second year of residency in obstetrics and gynecology, Naval Hospital, San Diego, Calif.
Comdr. Ross P. Black, Amarillo, Texas, course in basic science in urology, University of Pennsylvania.
Comdr. Nelse O. Olson of San Francisco, course in ophthalmology, Washington University, St. Louis.
Lieut. Comdr. August R. Buerkle, Pittsburgh, two year residency in orthopedic surgery, New York Orthopedic Dispensary and Hospital, Columbia University.
Lieut. Comdr. Wilbur S. Lummis, Newark, N.J., residency in internal medicine at a Naval Hospital.
Lieut. Don L. Andrus, Arlington, Va., course in surgery, University of Pennsylvania Graduate School of Medicine.
Lieut. John W. Trenton, Petersburg, W. Va., residency in general surgery, Naval Hospital, St. Albans, L.I., N.Y.
Lieut. (jg) James F. Berry, Alexandria, Va., residency in internal medicine, Naval Hospital, Bethesda, Md.
Lieut. (jg) John W. Flynn, Washington, D.C., residency in internal medicine, Naval Hospital, Bethesda, Md.
Lieut. (jg) Martin Koeck III, Chicago, residency in surgery, Naval Hospital, Long Beach, Calif.
Lieut. (jg) Bruce F. Baisch, Little Valley, N.Y., residency in surgery, Naval Hospital, Bethesda, Md.
Lieut. (jg) Livius L. Lankford, Cisco, Texas, residency in orthopedic surgery, Naval Hospital, Philadelphia.
Lieut. (jg) Walter G. Leonard, Newton, Mass., residency in obstetrics and gynecology, Naval Hospital, Chelsea, Mass.

CORRECTION

Officers Request Graduate Training.--In the list of Naval medical officers under this head in THE JOURNAL, April 17, page 1054, Comdr. James W. Gustin Jr. should have been listed as taking a residency in surgery at the Naval Hospital, Long Beach, Calif., instead of at the Naval Hospital, St. Albans, N.Y.

VETERANS ADMINISTRATION

NUMBER OF PATIENTS AT ALL TIME HIGH

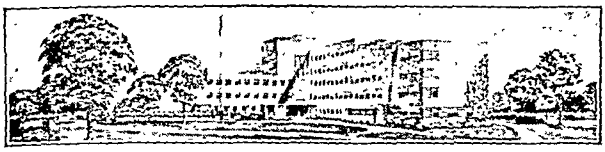
The number of veteran-patients hospitalized by the Veterans Administration reached the all time high of 109,325 on March 1, a gain of 1,874 over the previous peak of 107,451 on February 1. The number of veterans awaiting admission to hospitals also increased during February for the second straight month. The total on March 1 was 21,144, compared with 19,505 at the end of January and 4,329 in July 1945. The February increase was caused almost entirely by applications from veterans with nonservice-connected disabilities. Veterans Administration must provide medical care for veterans with service-connected ailments. Veterans with nonservice-connected disabilities may be hospitalized if beds are available and if they affirm that they cannot afford to pay for treatment elsewhere. Requests from veterans for physical examinations also reached an all time high on February 1 with a total of 256,000.

HOSPITAL AT OKLAHOMA CITY

President Truman and the Federal Board of Hospitalization have approved the acquisition of 9 acres of land in Oklahoma City for the site for a thousand bed Veterans Administration general hospital. The property adjoins Oklahoma University School of Medicine and the university hospital group. Locating the hospital on this site is in keeping with the Veteran Administration's policy of building large general hospitals close to medical schools and medical centers, so that the services of local medical personnel as residents, consultants and attendants may be available. All but three small parcels of land on the site are owned by the state of Oklahoma. The state's Board of Public Affairs has agreed to transfer its property, along with two of the privately owned lots on which it has options to purchase, to the Veterans Administration. The third privately owned lot will be acquired by the Veterans Administration.

HOSPITAL IN FORT WAYNE, IND.

On Sunday, February 29, ground-breaking ceremonies were conducted for the new Fort Wayne veterans' hospital, the construction of which is expected to start soon. The site of the two hundred bed general hospital is a 26 acre tract adjacent to the site of the new Methodist hospital which is to be built in the near future. The main building of the veterans' hospital will be a five story concrete structure with exterior walls of brick. There will be also recreational facilities for patients, radios with head phones or special pillow receivers for each bed, an auditorium, classrooms, shops, libraries and other facilities.



VETERANS ADMINISTRATION HOSPITAL AT FORT WAYNE, IND.

SPECIAL SPEECH TRAINING

About 100,000 veterans of World War II who suffered speech impairments in service may be eligible for special restorative training, the Veterans Administration announced. This training, which is available for veterans under Public Law 16, generally will be offered in speech clinics of medical centers, hospitals, colleges and public schools; in private speech correction clinics, in curative workshops and in speech clinics operating as adjuncts to mental hygiene clinics. The training is available when the speech impairment interferes with the employment of the veteran, when his mental and physical condition is such that the training may be pursued satisfactorily and when there is good promise that special training will overcome or reduce significantly the veteran's handicap.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ALABAMA

State Medical Elections.—At the annual meeting of the Medical Association of the State of Alabama in Mobile, April 15-17, Dr. J. Paul Jones, Camden, was elected president. Dr. Douglas L. Cannon, Montgomery, continues as secretary. The next annual meeting will be in Montgomery April 19-21, 1949.

Narcotic Violations.—The Bureau of Narcotics, Washington, D. C., has reported that two Alabama physicians pleaded guilty at Birmingham to information charging violation of the federal narcotic law. On February 27 Dr. William L. Drake, Fairfield, was fined $1,000 and placed on probation for five years, and on March 26 Dr. Robert B. Pryor, Mulga, was fined $2,000 and placed on probation for a period of three years.

CALIFORNIA

Society News.—The Los Angeles Society of Ophthalmology and Otolaryngology has elected Dr. Colby Hall, president, and Dr. Warren A. Wilson, secretary-treasurer.

Mental Health Institute.—A pilot institute on mental health for public health officers will be held in Berkeley July 5-18 under the auspices of the state department of public health and Commonwealth Fund. Lectures, seminars and supervised public health clinical experience in health department activities of the East San Francisco Bay region make up the program. Information may be obtained from the Director, California State Department of Public Health, San Francisco.

COLORADO

Rocky Mountain Cancer Conference.— The second Rocky Mountain Cancer Conference, sponsored by the Colorado State Medical Society, Rocky Mountain Cancer Foundation and Colorado Division of the American Cancer Society will be held at the Shirley-Savoy Hotel, Denver, July 14-15. Courses are designed particularly for the general practitioner. Among the speakers will be Fred W. Rankin, Lexington, Ky., on the colon and rectum; Herman L. Kretschmer, Chicago, urinary tract; Morris K. Barrett, Bethesda, Md., gastrointestinal tract; Alfred W. Adson, Rochester, Minn., brain and nervous system; Cly H. Hatcher, Chicago, bone; E. W. Alton Ochsner, New Orleans, lung; John H. Lawrence, Berkeley, Calif., isotopes; Richard H. Sweet, Boston, esophagus; John W. Budd, Los Angeles, laboratory diagnosis, and Archie C. Sudan, Denver, general practice. There is no registration fee as the conference is financed by contributed funds, mostly through the American Cancer Society.

FLORIDA

Personal.--Jesse Meuse, who has had many years of experience in the field of public health and teaching in public schools, has been appointed Negro health educator for the Florida State Board of Health. As a member of the division of health information he will work with various groups in the promotion of better health among the Negro population of the state.

State Medical Election.—Dr. Joseph S. Stewart, Miami, was installed as president of the Florida Medical Association at its annual meeting in St. Augustine April 11-14, and Dr. Walter C. Payne, Pensacola, was named president-elect. Dr. Robert B. McIver, Jacksonville, was reelected secretary-treasurer. The 1949 convention will be held at the Belleview Biltmore Hotel at Belleview.

Mobile Food Handlers School.--The Florida Food Handlers School program, which began in November 1947, is turning out about six hundred certified food handlers a month. Persons attending the mobile school must complete six hours' attendance before they receive their certificate as instructed food handlers. Thus far total attendance has been nearly 9,000. The school is a joint project of the Florida State Board of Health, Florida Hotel Commission and Florida Restaurant Association.

ILLINOIS

Dr. Huddleson Receives Bacteriologists' Award.—The Society of Illinois Bacteriologists at its spring meeting April 30 heard its first annual award lectureship delivered by I. Forest Huddleson, Ph.D., East Lansing, Mich., on "In Vitro and in Vivo Effect of Sulfadiazine and Normal Serum on the Brucella Antibody-Complement System." Dr. Huddleson was given the first annual award of the society for outstanding contributions to the science of bacteriology.

County Society Lectures.-- Lectures arranged through the Scientific Service Committee of the Illinois State Medical Society include:

May 20, Harry H. Boyle, Chicago, Effingham County Medical Society, Effingham, Nephritis in Childhood.

May 27, Franklin J. Corper, Chicago, Will-Grundy County Medical Society, Joliet, Infant Feeding.

May 28, Eugene L. Walsh, Chicago, McDonough County Medical Society, Bushnell, Chronic Bronchitis.

June 1, Leo K. Campbell, Chicago, Vermilion County Medical Society, Management of Diabetes Mellitus Complicated by Surgical and Obstetric Emergencies.

Chicago

Personal.--Adaline C. Hayden, formerly executive secretary of the American Association of Medical Record Librarians, has joined the staff at headquarters of the American Medical Association as associate editor of the Standard Nomenclature of Diseases and Standard Nomenclature of Operations.

Medical Society Sponsors Two Graduate Courses.—The Chicago Medical Society will sponsor two postgraduate courses in Thorne Hall on the Northwestern University Medical School campus this fall. A course in hematology and neurology will be given September 13-18 and one on cardiovascular and respiratory diseases September 20-25, with authorities from various parts of the United States teaching. Enrolment is limited to one hundred for each course. Applications may be sent to the office of the Chicago Medical Society, 30 North Michigan Avenue, Chicago 2.

County Hospital Appointments.—Dr. Oscar Felsenfeld, formerly of the Mount Sinai Medical Research Foundation, Chicago, has been appointed director of bacteriology at Cook County Hospital. Dr. Felsenfeld has just returned from the Caribbean area, where he spent seven months in a study of intestinal infections. He was stationed in San Juan, Puerto Rico. Miss Viola Mae Young, M.S., who has been working on parasitology at the School of Tropical Medicine at San Juan, Puerto Rico, has been appointed parasitologist. This position was recently created by the Board of County Commissioners.

Tuberculosis Centers.--Eleven of Chicago's seventy-five community areas contributed more than half the 4,296 cases of tuberculosis reported last year to the city health department. Dr. Earl E. Kleinschmidt, director of the Tuberculosis Institute of Chicago and Cook County, said that in addition to the cases reported there were about 10,000 Chicagoans who were infected with the disease during the year. The area from which the most cases were reported, 532, or 12.4% of the city's total, is on the near west side bounded by Kinzie and Sixteenth Streets, from the river west to Rockwell Street. The second ranking area with 354 cases is bounded by Thirty-Ninth and Fifty-First Streets, Cottage Grove Avenue, and the tracks of the Rock Island Railroad.

INDIANA

Resigns as Treasurer at Ninety.--Dr. Charles Hupe, aged 90, has resigned as treasurer of the Tippecanoe County Medical Society, Lafayette, after serving forty-six years in that capacity. Dr. Hupe, who has practiced medicine for sixty-four years, attends nearly all the meetings of the county medical society.

Centennial Celebration.--The council of the Indiana State Medical Association has selected Sept. 26-29, 1949 as dates for the Centennial Celebration of the association. The meeting will be held at Indianapolis, and one feature will be a "History of the Indiana State Medical Association" being prepared under direction of Dr. Charles N. Combs, Terre Haute, and Dr. Edgar F. Kiser, Indianapolis.

IOWA

Courses in Speech and Hearing.--The State University of Iowa College of Medicine, Iowa City, will offer two special courses on conservation of hearing during the 1948 summer session. The first, a four week intensive course in audiometry and the fitting of hearing aids, open to any one who can meet college entrance requirements, will run from June 21 to July 17. The second, an advanced seminar open to graduate students who have completed a first course in audiometry or who have had experience in public school or clinical testing, runs for eight weeks beginning June 9. In addition, a series of four lectures and round table discussions will be presented.

LOUISIANA

University News.--Drs. Carl Merrill Whorton and Frank C. Womack will join the faculty of the Louisiana State University School of Medicine, New Orleans, July 1 as assistant professors of pathology. Dr. Whorton is at present associated with the Mallory Institute of Pathology at Boston City Hospital and is on the staff of Tufts College Medical School. He was graduated at Vanderbilt University School of Medicine, Nashville, Tenn., 1940. Dr. Womack is an instructor in pathology at the Vanderbilt University School of Medicine, Nashville, Tenn. He received his M.D. at Vanderbilt in 1941 and served in the Navy during the war. A grant of $15,364 has been received from the War Department for continuation of studies on bacitracin in the department of surgery. The investigation was inaugurated on July 1, 1947 on a previous grant of $15,222 from the same source. The National Cancer Institute, U. S. Public Health Service, has awarded to the Louisiana State University School of Medicine a grant of $19,941 effective July 1, 1948 for development of the teaching and research programs in cancer. Dr. Walter J. Burdette, assistant professor of surgery, has been designated coordinator of the cancer program.

MASSACHUSETTS

Annual State Medical Meeting.--The annual meeting of the Massachusetts Medical Society will be held May 25-27 at the Hotel Statler, Boston, under the presidency of Dr. Edward P. Bagg, Holyoke. Guest speakers at the general sessions include:

Sumner L. Koch, Michael L. Mason and Harvey S. Allen, all of Chicago, Purposeful Splinting Following Injuries to the Hand.
Norman H. Jolliffe, New York, Nutrition in the Practice of Medicine.
Sir Reginald Watson-Jones, London, England, Significance of Rehabilitation in Medicine.
Robert B. Lawson, Winston-Salem, N.C., Recent Concepts on the Spread and Treatment of Poliomyelitis.
William S. Stone, M.C., U.S.A., Washington, D.C., Military Medical Preparations for the Future.
J. Rudolph Jaeger, Philadelphia, Subdural Hematoma.
Meyer Saklad, Providence, R.I., Operative Morbidity--Whose Responsibility?
Inglis F. Frost, New York, Endometriosis.
Eugene F. Traub, Burlington, Vt., Cutaneous Malignancies and Nevi.
Emery A. Rovenstine, New York, Management of Surgical Pain.
Hon. Forrest A. Harness, Kokomo, Ind., Government Propaganda and Socialized Medicine.

Guest speakers for the symposium on Liver Diseases Wednesday afternoon will be:

Henry G. Kunkel, New York, Liver Function Tests.
John R. Neefe, Philadelphia, Viral Hepatitis.
Stanley E. Bradley, New York, Variations in Hepatic Blood Flow.

The annual oration will be delivered by Dr. Allen S. Johnson, Springfield, Tuesday on "Responsibility of Medicine in the Propagation of Poor Protoplasm." The Shattuck Lecture will be given by Dr. C. Stuart Welch, Boston, on "Surgery in the Aged," on Tuesday evening at 8 p.m.

The guest speaker at the annual dinner Wednesday at 7 p.m. will be Mary Ellen Chase, Ph.D., Northampton, whose subject will be "The Country Doctor on the Maine Coast."

MICHIGAN

Hearing Testing Trailer.--The Michigan Department of Health has equipped a trailer to test hearing for use in its Hearing Conservation Program to school children in rural areas of the state. The 21 foot trailer has two rooms, one for controls and the other soundproofed for testing. More than 250,000 Michigan children have been tested for hearing loss under the Hearing Conservation Program since it was begun in 1942.

MINNESOTA

Chest X-Ray Survey in St. Paul.--During the chest x-ray survey carried out in St. Paul between October 22 and December 13, 1947, 694 cases of tuberculosis were discovered among 129,401 persons examined. The survey was conducted by the U. S. Public Health Service. St. Paul was the second of ninety-two cities of 800,000 or more population to take advantage of the offer. Twelve x-ray units were brought to St. Paul by the U. S. Public Health Service. Of patients whose tuberculosis was discovered by the roentgen examination and laboratory follow-up, 80 per cent were in the early stages of the disease.

Annual State Medical Meeting.--The Minnesota State Medical Association will meet in annual session at the Minneapolis Auditorium, Minneapolis, June 7-9, under the presidency of Dr. Archibald C. Cardle. A clinical-pathologic conference on cardiovascular-renal diseases and two panel discussions make up the opening general session program. The Russell D. Carman Memorial Lecture will be given by Dr. Paul C. Hodges, Chicago, on "The Role of X-Ray Pelvimetry in Obstetrics" Monday afternoon. The clinical-pathologic conference on Tuesday will be on acute abdominal pain, followed by panel discussions on nutrition in surgery and antibiotics. The Pediatrics Lecture on "St. Louis Encephalitis" will be delivered by Russell J. Blattner, Houston, Texas. On Wednesday's program there are a clinical-pathologic conference on uterine bleeding and the Arthur H. Sanford Lecture in Pathology by Benjamin J. Clawson, Minneapolis, on "Rheumatic and Bacterial Endocarditis." The general sessions will conclude with a public health meeting; among the speakers will be Senator Joseph H. Ball, on "National Health Legislation"; Robert L. Novy, Detroit, "Budgeting for Health Care," and Dr. Morris Fishbein, Editor of THE JOURNAL, on "Teamwork in the Conservation of Human Resources." A series of twenty-one round table discussions, each limited to forty, have been arranged, and scientific motion pictures will be shown each day. The annual dinner will be held at 7 p.m., June 8. The Physicians' First Annual Hobby Show will be held at the auditorium all during the convention. The Woman's Auxiliary will meet in conjunction with the state association.

NEW JERSEY

Research on Cell Growth.--Two recent grants totaling $71,450 from the New Jersey Division of the American Cancer Society, Inc., will be used at Princeton University, department of biology, Princeton, to conduct research on cell growth.

Personal.--Dr. William C. Williams, Rutherford, has been awarded the Russell Loines Memorial Award for Poetry of the National Institute of Arts and Letters. The award of $1,000 will be presented May 21 at the Academy Auditorium in New York. Dr. Williams, according to the *New York Times*, was recently appointed consultant of poetry in English by the Library of Congress.

NEW YORK

Receives Kaiser Medal.--The 1948 Albert David Kaiser Medal for outstanding medical service was awarded to Dr. John Aikman, assistant professor of pediatrics, University of Rochester School of Medicine and Dentistry, at a meeting of the Rochester Academy of Medicine May 4. Dr. Aikman has been in practice in Rochester for more than thirty years. He formerly served as chairman of the Section on Pediatrics of the American Medical Association.

Institute on Diarrhea of Newborn.—A regional Institute on Diarrhea of the Newborn will be held in the Buffalo Children's Hospital, Buffalo, May 24, 10:30 a.m. Sponsored by the Medical Society of the State of New York and the New York State Department of Health, the institute will serve the counties of Erie, Niagara, Chautauqua, Genesee and Wyoming. Hospital administrators, obstetricians and pediatricians, obstetric and pediatric nurses, laboratory directors and full time public health officers are invited to attend.

New York City

Harvey Lecture.—Dr. Frank A. Beach, professor of psychology, Yale University School of Medicine, New Haven, Conn., will deliver the eighth Harvey Lecture at the New York Academy of Medicine May 20, on "Nervous and Hormonal Mechanisms in Sexual Behavior."

Dr. Glenn Appointed Stimson Professor of Surgery.—Dr. Frank Glenn, assistant professor of clinical surgery, has been appointed Louis Atterbury Stimson professor of surgery at Cornell University and surgeon in chief of the New York Hospital to succeed Dr. George J. Heuer, who will retire. Dr. Glenn is a graduate of Washington University School of Medicine, St. Louis, and has been on the faculty at Cornell since 1932. He is the last of the Gorham Peters traveling fellows appointed by Dr. Harvey Cushing.

Dr. Price Retires from Department of Hospitals.--Dr. Thomas I. Price, general medical superintendent, Department of Hospitals, retired April 16 after thirty-nine years' service to the municipal hospitals. Employees of the central office of the department honored Dr. Price at a reception. A testimonial dinner also was held. During World War I he was assigned to the Army Medical College from 1915 to 1917; later, he became head of the Central Neurological Hospital. In 1922 he organized the New York City Cancer Institute with the late Dr. Isaac Levine, cancer specialist. He was medical superintendent of City Hospital on Welfare Island from 1938 to 1944 and on Feb. 1, 1944 was appointed general medical superintendent by Commissioner Edward M. Bernecker, M.D.

Doctor Composes Music for Doctors' Orchestra.--The Doctors' Orchestral Society of New York gave its annual concert at the Hunter College Auditorium on May 13. This symphonic group of seventy doctors, dentists and members of allied professions plays each year for some worthy benefit. This year the proceeds go to the charitable and educational program of the Physicians' Wives League of Greater New York. The feature of this concert was the world premiere of an orchestral suite called "The Hospital" composed by Dr. Herman M. Parris, University of Pennsylvania, Philadelphia, who has been composing orchestral and instrumental works for many years. "The Hospital" is written in ten movements depicting the reactions of a young woman who enters the hospital for an appendectomy. Her reactions at the information desk, with the nurse, the intern and the surgeon, and at the preoperative prayer, are described musically.

NORTH DAKOTA

Annual State Medical Meeting.—The North Dakota State Medical Association will meet in the Jamestown Armory, Jamestown, May 22-25 under the presidency of Dr. Philip G. Arzt of that city. The guest speakers will be:

Erling W. Hanson, Minneapolis, Stevens Johnson Syndrome.
John P. Caffey, New York, Roentgen Changes in Primary Tuberculosis.
Allan C. Barnes, Columbus, Ohio, Use of Female Sex Hormones in Clinical Practice.
Philip K. Arzt, St. Paul, Psychosomatic Medicine in General Practice.
Arthur Abt, Chicago, Diagnosis of Poliomyelitis.
Mavis P. Kelsey, Deport, Texas, Diagnosis and Treatment of Thyroid Disease.
Malcolm B. Dockerty, Rochester, Minn., Ovarian Neoplasms.

The annual banquet will be at the country club on Monday at 7 p.m. The Woman's Auxiliary will meet in conjunction with the state society.

OREGON

Southern Oregon Medical Society.—The annual meeting of Southern Oregon Medical Society will be held June 1 at the Oregon Caves Chateau near Grants Pass. Subjects under discussion include industrial accident commission practice and problems, newer concepts of electrocardiography in coronary artery disease, outlook for American medicine, obstetric problems met in premature labor, erythroblastosis and common surgical diseases of children. Members of the Oregon State Medical Society are invited. Reservations may be made by writing to the Oregon Caves, U. S. National Bank Building, Grants Pass.

PENNSYLVANIA

Survey of Public Health Activities.—The Pennsylvania Department of Health has requested the American Public Health Association to survey the public health activities of Pennsylvania. This survey was recommended last year by the Medical Society of the State of Pennsylvania. Important among the aspects of this survey will be the efficiency, scope and effectiveness of (1) the state department of health, (2) health service to local communities and (3) the relation of the state and local departments of health to voluntary agencies. A committee of public-minded citizens, to be appointed by Governor Duff, will serve in an advisory capacity. Dr. Roscoe P. Kandle, New York, field director of the American Public Health Association, is directing the study.

Philadelphia

Appoint Vice President and Deans of University.—Dr. Robin C. Buerki, dean of the Graduate School of Medicine and director of hospitals at the University of Pennsylvania School of Medicine, has been elected vice president of the university in charge of medical affairs. He will succeed A. Newton Richards, Ph.D., LL.D., who will retire after thirty-eight years of service. Dr. John McK. Mitchell has been elected dean of the School of Medicine as the successor of Dr. Isaac Starr, who asked to be relieved of administrative duties. Dr. William S. Parker will succeed Dr. Buerki as dean of the Graduate School of Medicine. A member of the medical faculty of the university since 1936, Dr. Parker has been assistant dean of the Graduate School of Medicine for two years.

TENNESSEE

State Medical Election.--At the annual meeting of the Tennessee State Medical Association in Nashville April 13-15, Dr. Hurley W. Qualls, Memphis, was installed as president and Dr. Nathaniel S. Shofner was named president-elect. Dr. William M. Hardy, Nashville, will continue as secretary.

Honor Dr. Hyman.—A portrait of Dr. Orren W. Hyman, dean of administration of the Memphis Division, University of Tennessee, Memphis, was presented to the university February 11, the gift of medical alumni and friends. Dr. Hyman received his LL.D. in 1938 from Southwestern College, Memphis. He has been with the University of Tennessee since 1913 and has been dean of administration and dean of medicine since 1925.

UTAH

Cancer Symposium.—A symposium covering advances in cancer etiology, diagnosis and therapy will be given May 28-29 at the University of Utah School of Medicine, Salt Lake City. Principal speakers include Dr. Austin V. Deibert, U.S. Public Health Service, Washington, D.C.; Dr. Frank B. Queen, Portland, Ore.; Dr. David A. Wood, San Francisco, and Dr. Andrew H. Dowdy, Los Angeles.

WASHINGTON

Appoint Professor of Obstetrics.—Dr. Russell R. DeAlvarez-Skinner, Portland, Ore., has been appointed professor of obstetrics and gynecology at the University of Washington School of Medicine, effective July 1. A graduate of the University of Michigan Medical School, Ann Arbor, he became instructor in the department of obstetrics and gynecology in 1938 and for several years served as consultant for the State of Michigan under the University's School of of Post-graduate Medical Education. Following service in the navy in the recent war, he engaged in private practice in Portland. Dr. Gordon G. Thompson, Seattle, has been appointed clinical professor of obstetrics and senior consultant in this department.

GENERAL

Society Elections.—The American Society for Pharmacology and Experimental Therapeutics, Inc., at the annual meeting March 16 in Atlantic City, N. J., elected Dr. Carl A. Dragstedt, Chicago, president, and Dr. Harvey B. Haag, Richmond, Va., secretary.

Headquarters of Academy of General Practice.—The American Academy of General Practice, organized a year ago at the convention of the American Medical Association, has established national headquarters at 231 West Forty-Seventh Street, Kansas City, Mo., with Mac F. Cahal, acting executive secretary.

Joint Orthopedic Meetings in Quebec.--The first combined meeting of the American, British and Canadian orthopedic associations will meet June 3-6 in Quebec, Canada. In addition to numerous papers by members of the associations, the speakers will include Drs. Malcolm B. Dockerty, Rochester, Minn.; Sten Friberg, Stockholm, Sweden; Philip C. Trout, Roanoke, Va.; Mary S. Sherman, Chicago, Ill.; Fuller Allbright, Boston; Arthur W. Ham, Toronto, William V. Cone, Montreal; and Kenneth G. McKenzie, Toronto. The Saturday afternoon program will be a round table discussion on undergraduate teaching in orthopedic surgery.

Section Meeting of Pathologists.—The Middle Eastern Region of the College of American Pathologists will meet in Washington, D.C., May 24-25 with headquarters at the Medical Society of the District of Columbia. The meeting is jointly sponsored by the local society of pathologists and the Section on Pathology and Laboratory Medicine of the district medical society. Various portions of the program are scheduled for the Naval Hospital, Bethesda, Md., Walter Reed General Hospital and the U.S. Public Health Service. Reservations should be sent to the Mayflower Hotel. Registration is open to all pathologists and other interested physicians. An attendance fee of $1 will be charged.

Gastroenterological Association.--The National Gastroenterological Association will hold its thirteenth scientific session in New York June 7-10. The program for the first three days will be at the Hotel Pennsylvania and will consist of symposiums on gastroduodenal ulcer; ulcerative colitis; jaundice and metabolism, and nutrition and allergy. The panel discussion will be followed by a " question and answer " period. At the banquet Tuesday evening, the winner of the National Gastroenterological Association's 1948 Cash Prize Award Contest for the best unpublished contribution on gastroenterology will be announced. Details may be obtained by writing to the Secretary, National Gastroenterological Association, 1819 Broadway, New York 23.

Science Writing Awards.--Competition for the George Westinghouse Science Writing Awards will terminate in July. The awards consist of two $1,000 grants, one to the author of the best newspaper science writing and the other to the writer whose work appears in a magazine of general circulation. The awards are administered by the American Association for the Advancement of Science from a grant by the Westinghouse Educational Foundation. Entries for this year's two awards must have been published in a newspaper between Oct. 16, 1947 and July 31, 1948 or in a magazine between October 1947 and July 1948. All entries must be in the judges' hands at the American Association for the Advancement of Science, 1515 Massachusetts Ave. N.W., Washington, D.C., by August 9.

Clinical Surgeons Annual Meeting and Tour.--The Southern Society of Clinical Surgeons will hold its eighteenth annual meeting at the Palmer House, Chicago, May 26, under the presidency of Dr. Emmett B. Frazer, Mobile, Ala. Subjects to be presented include heparinemia and hemorrhage, surgery of the stomach and the gallbladder, diagnosis of surgical jaundice and of congenital malformations of the heart amenable to surgical treatment. After a visit to the Veterans Hospital, Hines, Ill., the group leaves for Los Angeles, where they will attend sessions at the Los Angeles County Hospital; then on to Honolulu, where they will remain for a week during which the Honolulu Surgical Society will present a program. The group returns to San Francisco June 14, then goes to Portland, Seattle, Vancouver, Lake Louise, Banff and Winnipeg, participating in hospital clinics at various stops. They will return to St. Paul June 30.

Pan American Association of Ophthalmology.—Dr. Conrad Berens, New York, was elected president of the Pan American Association of Ophthalmology at the third Pan American Congress in Havana, Cuba, January 4-10. The next congress will be held in Mexico City in 1952. The Pan American Association of Ophthalmology was established as a continuing organization of the Western Hemisphere to promote measures to conserve eyesight and prevent blindness. The statutes provide for an Inter-American Federation of Ophthalmologic Societies and for a Bureau of Professors of Ophthalmology, who are to encourage the formation of centers for graduate study, to effect interchanges of professors and alumni among teaching centers, to arrange for and manage prizes and scholarships and to arrange for examinations and issue certificates of proficiency to physicians who seek them. The bureau's activities are not intended to interfere with independent examining boards already functioning efficiently.

American Surgical Association.—The American Surgical Association will meet at the Chateau Frontenac, Quebec, Canada, May 28-29 under the presidency of Dr. W. Edward Gallie, Toronto, Canada. In addition to numerous papers by members of the association, those invited to present papers are Warren H. Cole, Chicago; John H. Mulholland, New York; Laurence S. Fallis, Detroit; Frank H. Lahey, Boston; Frederick A. Coller, Ann Arbor, Mich.; Everett I. Evans, Richmond, Va.; Joe V. Meigs, Boston; Charles Huggins, Chicago; George M. Curtis, Columbus, Ohio; Ralph Colp, New York; Clarence Dennis, St. Paul; Gustav E. Lindskog, New Haven, Conn; George H. Yeager, Baltimore; Earle B. Mahoney, Rochester, N.Y.; Roy D. McClure, Detroit; Bradley L. Coley, New York; Jacob Fine, Brookline, Mass.; Howard C. Naffziger, San Francisco; Howard A. Patterson, New York; Loyal Davis, Chicago; John D. Stewart, Buffalo; Alfred Blalock, Baltimore; John S. Lockwood, New York; Lester R. Dragstedt, Chicago, and John H. Gibbon Jr., Philadelphia. There will be a formal dinner May 28 at 7:30 for fellows and guests of the association.

Awards in Mental Hygiene.--The 1948 Lasker Award of $1,000 for outstanding service in mental hygiene will be presented for a significant contribution to the education of the nonpsychiatric medical practitioner in the psychologic aspects of the practice of medicine. The work of candidates for the award must have been accomplished or generally accepted during the past year or two. Presentation of the award will be made at the annual meeting of the National Committee for Mental Hygiene, November 3-4 in New York. Any one may submit nominations, which should be forwarded by September 1 to the National Committee for Mental Hygiene, 1790 Broadway, New York 19.

National Safety Contest Winners.--The National Safety Council announced April 15 the winners in the National Traffic Safety Contest conducted by the council, in which six hundred and twenty-two cities of more than 10,000 population and forty-eight states participated. Oklahoma City and Wilmington, Del., tied for the grand award among the cities with a program which resulted in a reduction of 44 and 69 per cent, respectively, in 1947 traffic deaths as compared with 1946. Among cities of 500,000 and over Cleveland placed first, with Detroit and Washington, D. C., in second and third place. Oklahoma city won and Seattle placed second in the 200,000 to 500,000 class. Flint, Mich., placed second to Wilmington, Del., in the 100,000 to 200,000 group. In cities of 50,000 to 100,000 St. Joseph, Mich., won first place and Lakewood, Ohio, second. Dubuque, Iowa, was first in the 25,000 to 50,000 group with only two traffic deaths in 1947. Logan, Utah, won in the 10,000 to 25,000 group and maintained its previous two year record of no fatalities. Stillwater, Okla., second to Logan, completed its eighth year without a traffic fatality in 1947. Connecticut was the winner of the grand award for states with a mileage death rate (deaths per hundred million vehicle miles) of 4.3, half the national rate. Massachusetts and New Jersey tied for second place in the Eastern division. Virginia, Texas and Oklahoma, in that order, were winners of the Southern division, and Washington far outclassed other states in the Western region.

GREAT BRITAIN

International Postgraduate Courses. -- Roffey Park Rehabilitation Centre, Horsham, Sussex, is presenting international postgraduate courses on social and industrial psychiatry from June 28 to September 26. The first course extends from June 28 to July 4, the second from August 9 to 15, the third from August 23 to 29 and the last from September 20 to 26. Lectures and tours of rehabilitation centers make up the program. Accommodations for each course are limited to twenty-four persons, who will reside in a club on the estate. The fee, which covers tuition, residence and social activities, is $50. Early application for vacancies should be made to the Secretary, Roffey Park, Horsham, Sussex, England. Checks should be made payable to Roffey Park Rehabilitation Centre, Barclays Bank (Dominion, Colonial and Overseas), 120 Broadway, New York.

CORRECTIONS

Dr. Spurr Appointed Director of Hospital Clinic.—Dr. Charles L. Spurr, formerly on the faculty of the University of Chicago, has been appointed internist and director of the clinic at the M.D. Anderson Hospital for Cancer Research, Houston, Texas, not director of the hospital as stated in THE JOURNAL, April 17, page 1057.

Report of Officers.—In THE JOURNAL, May 8, among the "Reports of Officers," portions of other bureau reports were interposed between the two portions of the report of the Bureau of Health Education. On page 166, column 2, the report of the Bureau of Health Education apparently ends in the midst of a paragraph relating to "Pamphlets." This copy is continued on page 175, column 1, with the fourth paragraph which begins on that page, and it continues through to the end of the report of the Bureau of Health Education near the bottom of the second column of page 175. The latter portion of the report of the Bureau of Health Education was erroneously included in the report of the Bureau of Medical Economic Research.

Deaths

Neil Dugald Buie ⊕ Marlin, Texas; born in Scotland, Ark., April 11, 1879; Vanderbilt University School of Medicine, Nashville, Tenn., 1907; past president of the State Medical Association of Texas and the Falls County Medical Society; member and past president of the Federation of State Medical Boards of the United States; for many years member of the state board of medical examiners; member of the Association of Military Surgeons of the United States; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; member and past president of the local school board; member and past president of the Marlin Chamber of Commerce; past president of the East Texas Chamber of Commerce, of which he had been director and divisional vice president; owner of a hospital; chairman of the Falls County Foundation for Crippled Children; for many years health editor of the *Texas Outlook;* died February 9, aged 68, of heart disease.

Fred William Gaarde ⊕ Rochester, Minn.; born in Minden, Neb., June 20, 1887; Rush Medical College, Chicago, 1912; an instructor in medicine at his alma mater and an assistant on the attending staff at Presbyterian Hospital in Chicago from 1914 to 1920; joined the Mayo Clinic as an associate in medicine on Sept. 1, 1920; associate professor of medicine at the Mayo Foundation, where he served as head of a section of medicine and later as senior consultant in that section; a major in the medical corps of the American Expeditionary Forces during World War I; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the Institute of Medicine of Chicago, the Society of Internal Medicine of Chicago, Central Clinical Research Club and the Minnesota Society of Internal Medicine; died February 10, aged 60, of coronary insufficiency.

William Thompson Briggs ⊕ Lexington, Ky.; born in Nashville, Tenn., Aug. 19, 1881; Vanderbilt University School of Medicine, Nashville, 1909; past president of the Fayette County Medical Society; member of the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology; served during World War I; formerly a member of the faculty of his alma mater; for many years associated with the Lexington Clinic; on the staffs of Veterans Administration Hospital, Good Samaritan Hospital and St. Joseph's Hospital; formerly associate editor of the *Nashville Medical and Surgical Journal,* which later became the *Journal of the Tennessee State Medical Association;* died in St. Joseph's Hospital February 1, aged 66.

Walter Barclay Mount ⊕ Montclair, N.J.; born Feb. 5, 1880; Columbia University College of Physicians and Surgeons, New York, 1905; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and of the American Clinical and Climatological Association; fellow of the American College of Surgeons; served as secretary of the Society of Surgeons of New Jersey and as second vice president of the Essex County Medical Society; an officer serving during World War I; for many years affiliated with the Mountainside Hospital and the Montclair Community Hospital; died February 10, aged 68, of coronary occlusion.

John Alexander McCreery ⊕ New York; born in New York Oct. 19, 1885; Columbia University College of Physicians and Surgeons, New York, 1910; served as associate clinical professor of surgery at his alma mater; member of the founders group of the American Board of Surgery; member of the American Surgical Association; fellow of the New York Academy of Medicine and the American College of Surgeons; past president of the New York Surgical Society; served in France with the British and American Expeditionary Forces during World War I; for many years affiliated with Bellevue Hospital and the Greenwich (Conn.) Hospital, where he died January 31, aged 62, of pneumonia.

Charles Hume Baldwin ⊕ Utica, N. Y.; born in Medford, Mass., Dec. 23, 1876; Harvard Medical School, Boston, 1904; member of the American Academy of Orthopedic Surgeons and the Utica Academy of Medicine; fellow of the American College of Surgeons; served during World War I; chief of staff at the Children's Hospital Home since its founding; chief of staff of the Utica Dispensary and on the staffs of St. Elizabeth, St. Luke's and Faxton hospitals; visiting physician at the Pine Crest Sanatorium in Salisbury Center, and the Broadacres Sanatorium; died in Sanford, Fla., January 26, aged 71, of coronary thrombosis.

Hovsep Garo Adams, Fresno, Calif.; Boston University School of Medicine, 1914; affiliated with the St. Agnes Hospital, where he died January 28, aged 62, of heart disease.

Orville Lewis Adams, Aberdeen, Wash.; Rush Medical College, Chicago, 1906; member of the American Medical Association; served during World War I; affiliated with St. Joseph's Hospital; died January 28, aged 68, of intestinal hemorrhage.

Alex Eckel Bryan Alford ⊕ Bainbridge, Ga.; Columbia University College of Physicians and Surgeons, New York, 1909; medical director and owner of the Bainbridge Hospital; died January 14, aged 72.

H. Melvin Allen, Mount Penn, Pa.; Medico-Chirurgical College of Philadelphia, 1894; veteran of the Spanish-American War; on the staff of the Philadelphia General Hospital; died January 11, aged 78, of auricular fibrillation.

Nathan Johnson Bicknell ⊕ Detroit; University of Toronto Faculty of Medicine, Toronto, Canada, 1920; died in Harper Hospital January 28, aged 52, of hypertensive renal disease.

Oscar Henry Bohm ⊕ Yonkers, N.Y.; Columbia University College of Physicians and Surgeons, New York, 1901; past president of the Yonkers Academy of Medicine; formerly member of the board of education; served on the staff of St. Joseph's Hospital; died in the Yonkers Professional Hospital January 28, aged 70, of intestinal obstruction.

John Calhoun Boone, South Bend, Ind.; University of Louisville (Ky.) Medical Department, 1895; member of the American Medical Association; veteran of the Spanish-American War; served in France during World War I; died January 11, aged 82, of coronary thrombosis.

Bruce Hardy Brown, San Ysidro, Calif.; Barnes Medical College, St. Louis, 1910; served with the U.S. Department of Interior, in the medical Corps of the U.S. Army during World War I and two years with the U.S. Public Health Service; veteran of the Spanish-American War; died January 22, aged 66, of cerebral hemorrhage and hypertension.

Charles Wilson Conley ⊕ Columbus, Ohio; Eclectic Medical Institute, Cincinnati, 1895; Rush Medical College, Chicago, 1898; died in St. Francis Hospital January 28, aged 81, of cerebral hemorrhage.

Willis Frank Cotten ⊕ McComb, Miss.; University of Virginia Department of Medicine, Charlottesville, 1928; specialist certified by the American Board of Otolaryngology; served during World War I; past president of the Pike County Medical Society; affiliated with the McComb City Hospital and McComb Infirmary; served as president of the Chamber of Commerce, died in Baptist Hospital, New Orleans, January 19, aged 49.

James Rea Cowan, Van Nuys, Calif.; University of Southern California School of Medicine, Los Angeles, 1909; died January 19, aged 66.

Elijah Matthew Craighead Jr., Kimball, W. Va.; Meharry Medical College, Nashville, Tenn., 1928; assistant surgeon at the Welch Emergency Hospital; died in Lakin January 16, aged 43, of pneumonia.

Frederick Ellery Cruff, Norwell, Mass.; Harvard Medical School, Boston, 1920; member of the American Medical Association; served during World War II; died January 18, aged 55, of coronary thrombosis.

Paul Quincy Daniel, Grundy, Va.; Medical College of Virginia, Richmond, 1933; died in the Clinch Valley Clinic Hospital, Richlands, January 30, aged 41, of cirrhosis of the liver.

Eugene B. Dewees, Caneyville, Ky.; Hospital College of Medicine, Louisville, 1905; served as a member of the city and county board of education; died January 21, aged 68, of heart disease.

George Washington Dunn ⊕ New Britain, Conn.; Baltimore Medical College, 1909; past president of the Hartford County Medical Society; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; affiliated with the New Britain General Hospital, where he died January 31, aged 59, of cirrhosis of the liver and pernicious anemia.

Robert H. Flader, Webster Groves, Mo.; Missouri Medical College, St. Louis, 1897; died in the Deaconess Hospital, St. Louis, January 29, aged 73.

John W. Frizzell, Pasadena, Calif.; Homeopathic Hospital College, Cleveland, 1884; died January 19, aged 93, of bronchopneumonia.

Edward Henry Ganley ⊕ Methuen, Mass.; Tufts College Medical School, Boston, 1917; served during World War I; member of the Selective Service Board during World War II; affiliated with the Clover Hill and Lawrence General hospitals in Lawrence; formerly town physician; died January 23, aged 56, of congestive heart disease.

Lester Pierpont Gerrish ⊕ Lisbon Falls, Maine; Harvard Medical School, Boston, 1904; past president of the Maine Medical Association and of the Androscoggin County Medical Society; died recently, aged 72.

Andrew J. Glover, Guy, Ark. (licensed in Arkansas in 1903); past president of the Faulkner County Medical Society; died January 23, aged 78, of cerebral hemorrhage.

William Gregory Gunn ⊕ Versailles, Mo.; Barnes Medical College, St. Louis, 1909; fellow of the American College of Chest Physicians; died January 2, aged 62, of coronary thrombosis.

Allen P. Gurganious ⊕ Palatka, Fla.; St. Louis University School of Medicine, 1931; president of the Putnam County Medical Society; served during World War II; died in Elkton January 28, aged 41, of injuries received in an automobile accident.

George W. Haan ⊕ Aurora, Ill.; Illinois Medical College, Chicago, 1900; formerly city health commissioner; died in the Mercyville Sanitarium February 9, aged 83, of cerebral thrombosis.

Mary Gertrude Halton, New York; Cooper Medical College, San Francisco, 1900; member of the American Medical Association; died in Doctors Hospital January 25, aged 69, of pulmonary tuberculosis and pancreatic cyst.

John Ryland Harlow, Jonesboro, La.; University of Arkansas School of Medicine, Little Rock, 1935; interned at the Shreveport Charity Hospital in Shreveport; served overseas during World War II; died in a Kansas City, Mo., hotel February 7, aged 37, of pulmonary tuberculosis, cirrhosis of the liver and acute nephritis.

Edmund Henry Hedges ⊕ Lima, Ohio; St.Louis University School of Medicine, 1918; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; affiliated with Lima Memorial Hospital and St.Rita's Hospital, where he died February 11, aged 53, of coronary thrombosis.

George W. Heriot Sr., Savannah, Ga.; Atlanta Medical College, 1895; once served as city physician; died January 4, aged 79.

Verner George Heseltine, Taylors Falls, Minn.; L. R. C. P., London, and M. R. C. S., England, 1904; died in St. John's Hospital, St. Paul, Dec. 8, 1947, aged 71, of heart disease.

Patrick John Heston, Scranton, Pa.; College of Physicians and Surgeons, Baltimore, 1906; deputy county coroner; director of the women's division of the Pennsylvania State Sanatorium for Tuberculosis in Hamburg; on the staffs of the Mercy Hospital and State Hospital, where he died January 29, aged 61.

Frederick William Heyer ⊕ Nanticoke, Pa.; Medico-Chirurgical College of Philadelphia, 1912; specialist certified by the American Board of Surgery; member of the Radiological Society of North America, Inc.; fellow of the American College of Surgeons; chief surgeon at the Nanticoke State Hospital; died suddenly January 7, aged 61.

Joseph Howard Hodges, Martinsburg, W. Va.; University of Maryland School of Medicine, Baltimore, 1908; affiliated with the City Hospital; director and vice president of the Jefferson Security Bank of Shepherdstown, W. Va.; for many years medical examiner for the Baltimore and Ohio Railroad; died January 7, aged 65, of coronary thrombosis.

Walter Bayard Huey ⊕ Joliet, Ill.; Rush Medical College, Chicago, 1903; fellow of the American College of Surgeons; past president of the Will-Grundy Counties Medical Society; served as a member of the board of trustees of the Will County Tuberculosis Sanatorium; on the staff of Silver Cross Hospital, where he died January 25, aged 69, of arteriosclerosis and cerebral hemorrhage.

Virgil B. Jackson ⊕ Washington, D. C.; Columbian University Medical Department, Washington, D. C., 1894; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; member of the medical advisory board during World War I; at one time police surgeon; for many years on the faculty of his alma mater and on the staffs of George Washington University Hospital and Emergency Hospital, where he died February 15, aged 79, of prostatitis and renal calculi.

George Berlin Jastram ⊕ Aberdeen; Md.; Jefferson Medical College of Philadelphia, 1939; died January 31, aged 34, of cerebral hemorrhage.

Penicillin in Malignant Endocarditis Lenta

At a recent meeting of the French Society of cardiology, devoted to malignant endocarditis lenta, E. Donzelot, H. Kaufmann and J. Escalle reported 405 cases of this disease with treatment at the cardiologic clinic of the Broussais hospital. They classified these cases as of three types: (1) those with positive hemocultures; (2) those with negative hemocultures (25 per cent of the cases) and with parenchymatous lesions of the kidneys, spleen, liver and myocardium (in these cases treatment was particularly difficult, according to the authors, because of the behavior of the bacteria agglutinated on the vessel walls and in the visceral capillaries and also because of the lack of bacteriologic tests); and (3) those with subacute ulcers (often with negative hemoculture) and evoluting in several months toward cardiac insufficiency. The authors stress that the chief problem is estimation of the daily dose of penicillin to be given intramuscularly; it varies from 500,000 units in the more favorable cases to 50,000,000 units or more in more resistant cases In cases with positive hemocultures, three criteria are used to decide the dosage: (1) sensitivity of the organisms to penicillin; (2) hemocultures every fifth day during treatment, and (3) abrupt cessation of treatment twenty-five to thirty days after a negative hemoculture has been obtained and careful observation of the patient during the following month. Recovery resulted in 85 per cent of the cases with positive hemocultures and in 47 per cent of cases with negative hemocultures; there were 6 failures in the 6 cases of subacute primary endocarditis. In 8 cases with positive hemocultures G. Marchal obtained 5 apparent recoveries, lasting from four to thirteen months; 2 patients died from cardiac insufficiency and 1 from cerebromeningeal hemorrhage. The author stresses the necessity of improving the technic of hemocultures by modifying the culture mediums and increasing the number of sternal and splenic punctures. He thinks that impure fractions of penicillin may induce a functional myocardial insufficiency. G. Giraud emphasizes also the importance of myeloculture, which was positive in 2 cases with negative hemoculture. A. Camelin, A. Guibert, Noger and Tarel (Lyons) report 14 cases of subacute primary bacterial endocarditis with negative hemocultures and isolated aortic localizations, which were all penicillin-resistant. Sedillian and Monnet, in 25 cases of malignant endocarditis lenta, obtained 12 good results lasting from one to twenty-three months; they met with 10 failures, among which were 9 deaths in the course of treatment and 1 after an immediate good result but followed by an exacerbation. They, too, believe that penicillin is not without a harmful effect on the heart.

Endocarditis Due to Escherichia Coli

At the Claude-Bernard hospital, Morin, Dupont and Cavigneaux treated 2 patients with acute malignant endocarditis due to Escherichia coli, an uncommon affection (of which the world bibliography, studied by the authors, mentions 46 cases in sixty-two years). The first patient was a woman, aged 28, in whom five months after recovery from pyelonephritis due to Esch. coli, violent lumbar pain, hematuria, purulent urine and fever occurred suddenly. Blood culture was positive for Esch. coli. Despite sulfonamide therapy, the septicemia was complicated by icterus, azotemia and purulent meningitis, and there was a systolic murmur at the apex of the heart. Notwithstanding streptomycin therapy in a total dosage of 4,000,000 units given intramuscularly and of 500,000 given intraspinally, death occurred on the fourth day. Necropsy revealed large vegetations, in the form of a cauliflower, on the mitral orifice, and infarcts in the spleen and kidneys. The other patient was a woman, aged 38, in whom severe chills were followed by a temperature of 105.8 F. A definite menigeal reaction was noted, also an anemia with 2,600,000 red cells, azotemia and bronchitis. The patient received for five days a daily dose of 10 grains (0.65 Gm.) of sulfonamide compound, and for four days penicillin was given without any therapeutic effect; twelve days later, hemoculture was for the first time positive as regards Esch. coli. After hospitalization, hemoculture was again positive for the organism and 30 micrograms of streptomycin per cubic centimeter was necessary to inhibit its growth in vitro. After having been given during six days a total of 9 grains (0.58 Gm., 580,000 units) of streptomycin the patient died. At necropsy, on the wall of the right auricle, at a certain distance from the tricuspid orifice, a vegetation 1.5 cm. in diameter was found. The authors noted that the two patients had no rheumatic ancestors, and no prior cardiac condition. It is not possible to draw conclusions regarding the curability of endorcarditis due to Esch. coli, as the streptomycin therapy could not be used soon enough; higher doses, given under strict supervision, are to be recommended.

Medical Professional Developments in the Soviet Zone

In the Soviet-occupied zone of Germany certain developments in the medical profession reflect clearly the prevailing trend to do away with freedom of the individual for the sake of the totalitarian system. Within this system, the position of the physicians is not different from that of other persons, no better and no worse. One thing is clear: the physician in the Soviet zone of occupation has ceased to exercise freedom in his profession.

Registration Order for Physicians

On Jan. 15, 1947 a decree was issued by the Central Administration of Health in the Soviet zone of Germany, ordering the obligatory registration of all physicians with the stated purpose of organizing their proportionate distribution over the whole zone. The order appeals to voluntary cooperation by physicians in carrying out this plan but leaves no doubt that nonconformists have no other choice and must comply with the issued orders. All physicians within the zone have to register not only with local authorities but with the central agency. This registration is based on a questionnaire requesting a wide range of professional and personal data. The physician has to provide details concerning his training, qualifications, specialties and abilities in related fields. He must report within a week each material change in his personal circumstances, such as marriage, birth of a child, change of residence or professional activity, acquisition of a degree and the like. The duties to report such matters are so broadly worded that it is difficult to state their limitations, particularly in view of of the fact that, at the request of the Central Health Office, he has to appear at any time before that agency to answer in person any question deemed pertinent about his professional or personal life. The duty to report includes also the disclosure not only of his political past between 1939 and 1945 (as required by Control Council Directives 24 and 38) but of his present political activities. This is motivated by the desire of the central authorities of the Soviet zone to inquire into the extent to which the physician is participating in the political reorientation. Heavy penalties are provided for violation of the duty to provide information asked for by the order.

Medical Profession Part of Trade Union Organization

By circular letter of Nov. 28, 1946 the "Voluntary" organization of all physicians, dentists, apothecaries and veterinarians (irrespective of whether they exercise a free profession or are engaged on an employment basis) was established as *Fachgruppen* (professional groups) of the branch *Gesundheitswesen* within the provincial or territorial organization of the *Freier deutscher Gewerkschaftsbund*, the association of the Communist-influenced German trade unions. A local professional group may be organized in each town where there is a minimum of twenty members of the profession. Former nominal members of the Nazi party may be admitted but may not be office holders. These professional groups elect special committees for professional questions, scientific matters and economic problems, which cooperate with the provincial and central offices in carrying out the policies laid down by the official Health Administration.

Fair Play in Hospital Appointments

Nobody wants to cheat, but every one appreciates the advantage of a running start. Similarly, the old suspect and the young know that the other side is not endowed with the moral integrity of Caesar's wife. Hence the development in each of the three Scandinavian countries of a group of physicians with the title in Norway of the Association of Younger Doctors. As of January 1948 this group became a branch of the Norwegian Medical Association. In the annual report of this young association an account is given of some of the 346 instances in which it has intervened on behalf of its members. In as many as 243 of these cases the problem was one of salary or remuneration, and in 33 cases it dealt with complaints over hospital appointments. In 39 instances the problem concerned the working conditions, etc., of hospital physicians.

The situation becomes extremely delicate when the head of a public hospital indulges in preferences with regard to junior appointments which require the strictest impartiality. It is the duty of the head of the Norwegian Public Health Service, the health director, to make recommendations, but his is not always the last word. And even when it is, his decisions are sometimes challenged, although in his office a careful account is kept of the career and record of practically every physician in Norway. It is easy enough to allot points for terms of hospital service and the like, but how can one measure in figures such qualities as patriotism or the lack of it? It is easy enough to distinguish between a former quisling and a doctor whose patriotism entailed imprisonment during the German occupation, but in this field there are many other finer distinctions to be made. To many of these problems there is no clearcut solution, but the Association of Younger Doctors is at work to make hospital appointments as fair as possible in this hard and competitive world.

The Scandinavian Medical Press

A few years ago nearly all the really important medical journals in Denmark, Finland, Norway and Sweden joined forces in a conglomerate publication known as *Nordisk Medisin*. This weekly publication contributed much to the prestige of Scandinavian medicine abroad, but at home it did not give full satisfaction. It was objected that by keeping to national watertight compartments the editors had failed to produce a cohesive publication reflecting the universal character of medical science. Might not national grouping of the subject matter give place to a scientific grouping which paid no heed to national boundaries? This question and many others were discussed and a satisfactory compromise was achieved, resulting in the issue of this publication at the beginning of 1948 in a much changed form. *Nordisk Medisin* has now become *Nordisk Medicin*. A staff of specialists has been engaged to contribute unsigned editorials and comments, and the space allotted to each signed article has been strictly rationed. This rationing has been effectively applied also to the transactions of medical societies, and space has been found for short case records, therapeutic hints and a host of minor details likely to interest the general practitioner as well as the research worker. Original articles are grouped so that individual articles on the same subject treated from different points of view. Notes on persons as well as on things are particularly useful to the Scandinavian reader wanting to know who's who in neighboring countries.

The Fate of Objectors to BCG

In the tuberculosis department of Oslo's Municipal Public Health Service the rule has been practiced for several years of offering every tuberculin-negative youngster intracutaneous BCG vaccination when a radiologic examination of the lungs is negative. Those who object to BCG vaccination (and hitherto every one has been free to object, but no longer) serve as controls, both the BCG-vaccinated and the objectors being kept under supervision for years after leaving school. Dr. G. Hertzberg has recently published such a control comparison, his material concerning youngsters who, at the age of 13, accepted or refused BCG vaccination. Among the 127 boys and 106 girls who were vaccinated, there were only 1 boy and 1 girl in whom signs of tuberculosis subsequently developed, whereas among the 66 boys and 75 girls who refused BCG vaccination there were 34 boys and 43 girls who subsequently showed signs of tuberculosis. This investigation covered the period 1941 to 1946 and included all the youngsters belonging to the two categories studies. But the total BCG-vaccinated material of this tuberculosis department now amounts to well over 18,000 persons, whose careers will shortly be the subject of a comprehensive monograph on BCG vaccination.

Correspondence

CONTAMINATED DEXTROSE SOLUTION

To the Editor:—We are reviewing every procedure and record and testing every piece of equipment in the department involved, but at this moment we still do not know the cause of the contamination in some of the bottles of two lots of dextrose solution. The original tests were satisfactory, and retained samples and stocks remaining in our Berkeley warehouse were not contaminated. Some of the bottles returned from the field were unquestionably contaminated, a contamination which was apparent on visual inspection and viable on culture.

This laboratory has over a half century record of safety in the production of bioligicals and other products for parenteral injection. It is a record which neither management nor the men and women of unquestioned capability and integrity who staff the laboratories would wilfully jeopardize. Yet what was to us inconceivable happened. I need not protest of our extreme regret for this most unfortunate occurrence.

ROBERT F. CUTTER, M.D.,
President, Cutter Laboratories,
Berkeley, Calif.

Note.—The unfortunate experience of the Cutter Laboratories indicates the necessity for constant vigilance, particularly as relates to materials to be injected intravenously or otherwise into the human body. Apparently the Cutter Laboratories are doing everything possible to detect the source of contamination and to eliminate any such possibility for the future.—Ed.

THE EPILEPTIC DRIVER

To the Editor:—In the April 17 issue of THE JOURNAL, page 1062, Dr. Wartenberg of San Francisco commended the four states that require physicians to report cases of epilepsy to the state board of health in order that the drivers' licenses may be revoked. He hopes that other states will enact a similar law. I wish to register my vigorous objections to such a law.

It defeats its own purpose in that many epileptic drivers may hesitate to seek the medical advice that might rid them of seizures and make them safe drivers. There is a more important objection. The California law applies to persons who have "lapses of consciousness which may be chronic." Only a minute proportion of persons who answer to this description are epileptic. Probably a hundred times more numerous are those who have recurrent impairment of consciousness because of an excessive use of alcohol. If Boards of Health and Registrars of Motor Vehicles are genuinely interested in putting dangerous drivers off the road, let them require that physicians report their alcoholic patients and *persons subject to syncope or heart attacks*, as well as those with epilepsy. I understand that some at least of the states commended by Dr. Wartenberg enacted this law without prior consultation with medical authorities. The state of Massachusetts has followed a more sensible course. The Registry of Motor Vehicles has asked physicians belonging to the League Against Epilepsy for advice regarding the licensing of epileptic persons, the possibility of electroencephalographic examinations in doubtful cases and the willingness of these physicians to assist in judging individual cases. Everyone desires greater highway safety. No one condones the licensing of the active epileptic; but to pick this small group out of the large mass of persons whose physical condition makes them a highway hazard and to require that their diagnosis, regardless of all circumstances, be reported to a nonmedical public agency is both unwise and unjust.

WILLIAM G. LENNOX, M.D., Boston.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Life Insurance: Death of Insured Following Abortion.--The plaintiff, as beneficiary, sued to recover on three life insurance policies issued to the deceased by the defendant insurance company. From a judgment for the plaintiff, the defendant appealed to the court of appeal of Louisiana, Orleans.

Each policy sued on provided in effect that no benefits would be payable if the insured died as the result of a violation of the law. The death of the insured resulted from acute tetanus following a criminal abortion, to which she had voluntarily submitted.

The defendant first contended that the deceased was an accessory to the abortion, which is a crime, and that the aforementioned provisions of the policies therefore absolved it from liability. The definition of the crime of abortion as found in the Louisiana criminal code, the court said, indicates that it was the legislature's intention to make the person who feloneously administers a drug or potion or any other substance to a pregnant woman, or who uses any instrument or any other means whatsoever on a pregnant woman, for the purpose of procuring a premature delivery of the embryo or fetus, guilty of the crime of abortion. The language used in the definition is not broad enough to show an intention to include a woman who consents or submits herself to an abortion, however, even though such woman is guilty of a detestable and revolting offense against the laws of nature. The defendant is absolved from liability in this case only if an unlawful act perpetrated by the insured caused her death. If it was the intendment that the insurer would not be liable if the criminal act causing death was that of a third person, a case might arise in which an innocent policy holder, without provocation, was feloniously killed by another, in which event the insurance company would be relieved of paying the policy, as it could be said that the death arose from a criminal act, even though the insured played no part therein, except being the victim. A provision of a life insurance policy relieving the insurer from liability where death results from a violation of the law is to be given a reasonable and common sense construction. We believe, the court concluded, that the exclusion of liability clause in question was intended to apply only in cases where death resulted from a violation of the law by the insured herself.

The defendant next argued that the act causing the insured's death was of a heinous and abhorrent character and that public policy precluded insuring her against its consequences. The record does not show what relationship, if any, existed between the plaintiff and the deceased, nor is it shown that he had any knowledge of the deceased's intention to submit to the operation or played any part in it. The plaintiff is, however, the designated beneficiary and seeks the recovery individually and for his own account. The question presented, said the court, is therefore: Should the plaintiff here, who is the named beneficiary of life insurance policies, be allowed to enforce collection of the policies where the death of the insured resulted from a criminal operation, the policies not expressly providing against the insurer's liability for death from such a cause?

It seems to be the general rule, the court of appeal said, to take into account two different classes of life insurance policies, one class being those policies made payable to the assured's estate, or to his personal representative by some appropriate designation, and the other class being those policies in which some third person is nominated and designated as beneficiary. The weight of authority appears to be to the effect that a person or his estate should not profit as a result of his own wrongdoing, and that when the maturity of an insurance contract made payable to the estate, or to the personal representative, is hastened or accelerated by his wrongdoing, even in the absence of any prohibitory clause in the contract, no recovery can be had on the policy. It is otherwise in cases involving policies in the latter class, i.e., those running in favor of third persons as beneficiaries, on the theory that the beneficiaries, having acquired a vested interest in the policies, cannot be either divested thereof or jeopardized therein, after issuance of the policies, by any wrongful act of the insured not excluded from coverage, for which they are not responsible. Even though the deceased came to her death as a result of the illegal operation for abortion to which she had voluntarily subjected herself, such submission on her part, which was reprehensible and detestable, cannot be used by the insurer as a valid defense to absolve itself from the payment of the proceeds of the policies to plaintiff, as plaintiff appears individually and as the designated beneficiary, having a vested interest in the policies. His rights as beneficiary could not be affected, and were not affected, in any way by the act of the insured, for which he was in no way responsible; there is no reason for disregarding the terms of the contract of insurance and exonerating the insurer on the grounds of public policy. Accordingly the judgment of the trial court in favor of the plaintiff was affirmed.—*Payne v. Louisiana Industrial Life Ins. Co., 33 So. (2d) 444 (La., 1948).*

Medical Motion Pictures

FILM REVIEWS

Human Reproduction 825 feet (one reel), showing time twenty-three minutes.

The anatomy, physiology and general functioning of the human reproductive system is well shown in this film. Outstandingly successful is the explanation of ovulation and menstruation. The subject is explained with fine scientific accuracy and complete objectivity so that there should be no embarrassment in either sex, though it would appear wise to show this film to college men and women in segregated groups. The essential facts that college men and women should know about the structure and function of the reproductive system are shown in such a way as to be easily understood. This film should be useful in the instruction of college groups, selected high school groups, nurses and teachers. A silent follow-up film strip, consisting of scenes selected from the corresponding motion picture over which questions are superimposed, accompanies each motion picture. Photography is excellent and the animation is well done.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Castle's Intrinsic Factor in Human Stomach.—Landboe-Christensen and Plum made dried powdered preparations from the fundal and from the pyloric parts of the wall of the human stomach. Feeding of 100 Gm. of dried powdered and defatted stomach wall from the anatomic fundal part of the human stomach to a patient with pernicious anemia produced a striking therapeutic effect. This demonstration of high antipernicious anemia activity of human fundus powder agrees with the observations of Fox and Castle and corresponds with the localization of the pathologic changes in the stomach of patients with pernicious anemia. The effectiveness of human fundus powder is in contrast, however, to the total ineffectiveness of hog fundus. The feeding of 80 Gm. of powdered stomach wall from the pyloric part of the human stomach to a second patient with pernicious anemia produced a moderate therapeutic effect. The effect was less than in the case treated with fundus powder. The authors conclude that antipernicious anemia activity occurs not only in human fundal glands, but also in human pyloric glands.

Experimental Heat Pyrexia.—Daily and Harrison use the term heat pyrexia synonymously with heatstroke. They produced heat pyrexia in dogs, rats and mice by exposure to high environmental temperatures. Except for differences related to the sweating mechanism, and the more rapid course of events in smaller animals, the clinical picture of heat pyrexia in animals resembles closely that seen in man. On the basis of the studies in animals, the author suggests a treatment for human subjects with heat pyrexia. If the patient is comatose, or if body temperature is above 41 C. (106 F.), he should be immersed in ice water. Milder instances may be treated by evaporative cooling. The oral temperatures should be followed minute by minute during the process of cooling. At an oral temperature of about 38.5 C. (101 F.) the patient should be moved to a tub of water at about 38 C. After the body temperature has stabilized at a normal level, hydrotherapy may be discontinued. If manifestations of shock—gray skin, slow filling of blanched areas, poor filling of veins behind a tourniquet and severe hypotension—are present, infusions must be given with great caution, the venous pressure, state of breathing and breath sounds being continously observed. Rapid digitalization is probably indicated if pulmonary edema or rising venous pressure develop. Oxygen therapy may be valuable when either peripheral failure or pulmonary edema is present. The patient's temperature must still be watched after the emergency state has passed. Attention should be given to fluid and electrolyte requirements.

Thiouracil and Propylthiouracil in Management of Thyrotoxicosis.—Grauer and his associates report the clinical effects and the laboratory response to thiouracil and propylthiouracil observed in 100 thyrotoxic patients treated over a period of almost three years. The galactose thyroid function test was helpful as a therapeutic guide and as a diagnostic supplement to the basal metabolic rate in 70 per cent of the patients. The proplylactic use of "solubilized" liver as a source of folic acid failed to prevent the occurrence of 1 case of agranulocytosis, 1 case of granulocytopenia and 2 cases of leukopenia in thiouracil-treated patients. Neither the use of pyridoxine intravenously nor large doses of folic acid stimulated granulocytosis. Propylthiouracil is less toxic and more potent than thiouracil and apparently can be used with relative impunity in thiouracil-treated patients. Ten of the 15 thyrotoxic patients treated medically with thiouracil showed a remission of from seven to twenty-three months. The presurgical preparation of thyrotoxic patients with the antithyroid drugs lessens the mortality rate and decreases the period of hospitalization.

Evolution of Silicotic Lesions.—Costero says that earlier descriptions of the microscopic appearance of silicotic lesions are based on the classic staining technics with aniline dyes. He studied 35 cases of pulmonary silicosis with the silver impregnation technics of Rio-Hortega and has described a number of little known structural details, which may contribute to a better understanding of the evolution of the silicotic nodule and which explain presence of those other nonnodular lesions that are constantly observed in the lungs of patients with silicosis. The histologic basis of all lesions induced in the human lung by siliceous dust is proliferation of reticular fibers. These fibers are partially or wholly transformed into collagen and undergo hyalinization and retraction. The silicotic node continues its growth as long as there are reticular fibers; growth is arrested when collagenization is complete. In addition to the typical silicotic nodule there also appear diffuse sclerotic plaques, peribronchial sclerosis and proliferative pleuritis. These three lesions have special characteristics which can be related to the different types of lymphatic drainage in each region; however, their histogenesis, structure and evolution are similar to those of the typical silicotic nodule.

Vitamin A Deficiency and Thyroid Function.--The lack of agreement concerning the effects of vitamin A deficiency on thyroid function induced Lipsett and Winzler to investigate this problem with the use of radioactive iodine (I^{131}) as a tracer. They found that despite the increase in size of the thyroid glands of the viatmin A-deficient rats the total uptake of radioactive iodine was the same as in the control animals. In vitamin A deficiency the percentage of inorganic I^{131} in the thyroid gland reached higher than normal values and decreased more slowly than in the controls. Vitamin A deficiency decreased the rate of formation of thyroxine. These results indicate that iodine metabolism is abnormal in the vitamin A-deficient rat.

Vitamin K Tolerance Test and Hepatic Function.—This study by Unger and Shapiro is an extension of the study of Shapiro and Richards embodying the principle of imposing a load on the liver by the parenteral administration of large doses of vitamin K. This same principle is utilized in other liver function tests such as sulfobromophthalein sodium retention, bilirubin clearance, dextrose tolerance and galactose tolerance tests. Reaction to injection of vitamin K is correlated in patients with hepatic disease and in normal controls with the results of other liver function tests and liver biopsy or postmortem observations. A standardized vitamin K tolerance test estimating the prothrombin response to parenteral administration of large test doses of vitamin K has been used. One hundred and thirteen tests were made on 110 persons. Of these, 47 were interpreted as negative, 9 doubtful and 57 positive. The authors found the test to be a sensitive indication of hepatic function. It is of considerable sensitivity in measuring hepatic function of prothrombin formation and serves as a good index of the presence or absence of hepatic disease. Excellent correlation with clinical observations indicative of impaired hepatic function were obtained.

Involvement of Liver in Mononucleosis.—Evans compared results of the cephalin-cholesterol flocculation test in the serum of patients with infectious mononucleosis without jaundice and with results of other liver function tests. Serial determinations were made in 19 consecutive cases of infectious mononucleosis without jaundice. Results indicate that demonstrable hepatic impairment occurs in many such cases. The cephalin cholesterol flocculation test may be a more sensitive indicator of this disturbance than the thymol turbidity test. Use of the cephalin cholesterol flocculation and the thymol turbidity tests may be helpful in distinguishing infectious mononucleosis from uncomplicated upper respiratory infections. The author directs attention to the hepatic involvement in infectious mononucleosis and infectious hepatitis.

Current Problems in Aviation Medicine.--Grow states that new methods of propulsion, jet and rocket engines, which make possible flight at hitherto unattainable altitudes and at supersonic speeds, have brought with them the problem of supplemental oxygen. Above 42,000 feet (12.8 kilometers) 100 per cent oxygen must be supplied under pressure. This so-called " pressure breathing" is necessary for unpressurized cockpits and cabins. An alternative is to seal the cabin or the cockpit and introduce a maximum of oxygen and nitrogen under pressure to supply the pilot with an atmosphere equivalent to a lower altitude. Cabin pressurization is now included in Air Force specifications. Extreme cold at high altitudes requires some form of cabin heating, but the temperature control is further complicated by the fact that at supersonic speeds the friction of air on the surface of the aircraft increases the temperature inside the aircraft, so that it may be necessary to refrigerate rather than heat the cabin. Another great problem is acceleration experienced in rapid takeoff of high speed aircraft. Research is required to solve these many problems.

Cancer Potential in Involuting Organs.--Crossen discusses potential danger of development of cancer in the involuting uterus and ovaries and indicates that primary ovarian carcinoma is the most insidious of the pelvic cancers and the one most frequently overlooked until it has reached a hopeless stage. To reduce deaths from carcinoma of the ovary the author recommends removal of the involuting ovaries whenever the abdomen is opened in the age period of involution (42 or later). Radical surgical procedures instead of conservative measures in noncancerous conditions, which occur in the age of involution, such as uterine myoma, pelvic endometriosis, nonmalignant ovarian enlargements and the chronic inflammatory lesions of uterus and adnexa, are recommended. With regard to prevention of cancer in the endometrium, the author states that circumstantial evidence points to the prolonged action of endogenous estrogen after the menopause as an important factor. He believes that it is better to stop estrogenic activity at approximately age 50, or sooner, if the periods are abnormal, rather than run the risk of continued endometrial stimulation at a time in life when the endometrium should be atrophic. This can be done by radium therapy, and early carcinoma can be ruled out by curettage. Warning is given with regard to the use of estrogenic hormones in the menopause and in cases of hyperplasia. Large doses of estrogenic substances during menopause are considered unwise. Troublesome symptoms can be controlled by small doses of thyroid plus phenobarbital.

*Congenital Extrinsic Duodenal Obstruction in New Born: Report of 2 Cases. J. S. Stewart.—p. 15.

Duodenal Obstruction in the Newborn.—Stewart directs attention to the high mortality in congenital duodenal obstruction of the newborn and shows that it is always associated with abnormalities of position and fixation of the intestines. He reviews the embryologic stages of rotation of the intestines and in particular of the midgut, in an attempt more clearly to understand the anatomic arrangement of the intestines which is found when there has been interference with normal rotation. He demonstrates the importance of delivering the intestines onto the abdomen as a technical step in the surgical managament of this type of obstruction. Vomiting is the chief complaint in intestinal obstruction of the newborn. Abdominal distention is not a symptom; the only distention that is usually seen is that of the stomach itself, and then only when it has not emptied itself by vomiting. The absence of abdominal distention is probably the chief reason for delay in diagnosis, the physician being loath to make a diagnosis of intestinal obstruction in the absence of something that he can see or feel. The differential diagnosis between hypertrophic pyloric stenosis and extrinsic duodenal obstruction is that the former seldom occurs before the second week of life and bile does not appear in the vomitus, whereas in the latter vomiting begins early, even on the first day, and the vomitus usually contains bile. The authors describe 2 hitherto unpublished cases of extrinsic duodenal obstruction in the newborn.

Book Notices

A Practical Textbook of Leprosy. By R. G. Cochrane, M.D., Ch.B., F.R.C.P., Principal, Missionary Medical College, Vellore, S. India. With a foreword by George R. McRoberts, C.I.E., M.D., F.R.C.P. Oxford Medical Publications. Fabrikoid. Price, $11.50. Pp. 283, with 186 illustrations. Oxford University Press, 114 Fifth Ave., New York 11: Amen House, Warwick Square, London, E. C. 4, 1947.

Dr. Cochrane has been an outstanding student of leprosy for many years, having had large experience with clinical, administrative and research phases of this disease. Scarcely any one has had better opportunity to become familiar with all aspects of the infection. This large experience has nearly all been in British India, and throughout the book this limitation is reflected.

Of the twenty-two chapters, six are devoted to treatment, two to prevention, and the remaining fourteen cover the other fields of interest. It may be said that this is a very useful volume; indeed it would be indispensable for those required to deal with the problem on any considerable scale and of great value to the physician called on but seldom to be responsible for the care of cases. From the point of view of public health it may be said the author is progressive and sound. He advocates dealing with cases on a rational basis, considering the clinical type and the danger of infection from the individual case and the environment in which the patient is to live. While he believes in the great danger of infection in childhood, he recognizes that the danger may exist into the period of youth. He believes that the key to successful preventive measures is to be found in avoiding exposures of children. The author objects to use of the word "leper" and hopes that the book will aid in dispelling the widespread repugnance to the disease which even some physicians entertain. The chapter on pathology deals largely with early lesions and the subject as related to clinical changes and immunologic phenomena. The author does not accept the view that there is a recognizable primary or initial lesion.

Leprolin, or lepromin, about which so much is being written, Cochrane regards as not of importance in diagnosis. However, he considers a positive reaction as an evidence of successful tissue defense, therefore of prognostic importance. There is a useful and detailed account of the technic of taking specimens from cutaneous lesions for microscopic examination, but the illustration shows a skin incision of much greater extent than that required to obtain necessary material. There is a needed caution about regarding the nose as a place for securing specimens for early diagnosis and a warning respecting nonpathogenic acid-fast bacilli likely to be found in the nose. There is a timely warning in regard to "enlarged" nerves and a caution that when in doubt it is better not to regard the nerve as enlarged. The author discourages the use of the expression "incubation period," preferring to use "latency."

In these days when so much thought is being given to psychosomatic medicine one should not be greatly surprised to find the author laying stress on the importance of Christian faith on the part of the doctor as well as on the part of the patient, but this attitude does not blind him to the need for rational therapy. Dr. Cochrane recognizes the tendency of the disease to undergo spontaneous arrest or cure, but he also believes in the use of therapeutic agents. He considers chaulmoogra oil the most useful. Although in the text the author speaks of chaulmoogra oil as the sheet anchor in therapy, in the foreword Dr. George R. McRoberts, professor of medicine at Madras, states that "too much success has been claimed for chaulmoogra oil and its derivatives, and irresponsible optimism with regard to their value has deflected attention from the acute need for more active search for effective chemotherapeutic weapons." The author is well acquainted with the newer drugs in use; however, he states that not enough experience has been had with "promin" and "diasone" for a final appraisal of these drugs. The surgical management of complications is fully discussed. He thinks that patients should be treated in general hospitals when circumstances do not demand or warrant special institutional care. Considerable space is given to reactions that occur during the course of the disease. There is some evidence of careless proofreading—thus we find Langham's where Langhans' is intended. In a legend under an illustration, a lesion is designated as on the left back whereas it is on the right; specific names are not italicized and sometimes not capitalized. On page 41 it is stated that lepromin cannot be standardized, while on page 42 it is said to be difficult to standardize. There are a few other points to which exception may be taken. The date of the "black death" is given as 1340. The one usually accepted is 1348. Some therapeutic agents are referred to by trade names.

A Neuro-Vascular Syndrome Related to Vitamin Deficiency. Door Hendrik Smitskamp. Academisch proefschrift ter verkrijging van de graad van Doctor in de geneeskunde aan de Universiteit van Amsterdam. Paper. Pp. 111, with illustrations. Scheltema & Holkema's Boekhandel en Uitgeversmaatschappij N.V., Rokin 74-76, Amsterdam, 1947.

From his experience in the careful study of 347 cases of burning and painful sensations in the extremities, loss of vision and signs of disturbance of the vestibular apparatus occurring in European prisoners of war interned by the Japanese in Java, the author believes that he has uncovered a new syndrome mainly due to a deficiency of the vitamin B components. It is to be distinguished from the three main groups of vitamin B deficiencies; beriberi, pellagra and hyporiboflavinosis. It is thought most probably to be due to a deficiency of pantothenic acid, in combination with an unusual composition of the diet. Ocular changes occurred in 42.8 per cent of the patients and consisted of the development of scotomas, blurring of vision and occasionally an irreversible optic atrophy. The otoneurologic aberrations occurred in 27.8 per cent of the patients and were characterized by complaints of vertigo, loss of hearing and hyperexcitability of the vestibular apparatus. This symptomatology is supposed by the author to be caused by a dysfunction of the autonomic nervous system. The lesions are probably located in the sympathetic ganglions and perhaps in higher centers of the cord and brain. The arguments in favor of naming this a syndrome are cogent and helpful in straightening out the confusion that exists regarding beriberi and the allied conditions Those interested in nutrition, ophthalmology and otology will find much of value in this well written monograph.

Hematomas subdurales: Generalidades, sintomatologia, bibliografia. Por el Dr. Alfonso Asenjo. Second edition. Paper. Price, 300 pesos. Pp. 251, with 49 illustrations. Stanley, Manuel Rodriguez N. 852, Santiago, Chile, 1947.

In this small book fifty of the two hundred and fifty pages are occupied by a lengthy bibliography. The remainder contains extensive extracts from the literature, numerous case histories and statistics concerning the 67 cases in the author's personal experience. From this material the author finds that about 1.5 per cent of traumatisms of the head are complicated by a hematoma. Ipsilateral symptoms were observed in 12 instances, confusion or obnubilation in 40, papillary edema in 16, motor pareses in 45 and epileptic attacks in 20. There was usually a slight increase in pressure of the spinal fluid, xanthochromia and slight pleocytosis. The electroencephalographic findings were not helpful. Arteriography was not used. Radiography was found useful. One might find signs of intracranial hypertension in children, displacement of the pineal body, old fractures or, infrequently, unusual calcifications. Ventriculography demonstrated displacement, distortion of the ventricles or partial lack of filling of ventricles or subarachnoid space. In general the observations in this report vary only in minor statistical details from generally accepted opinions.

Mainspring: The Grassroots Story of Human Progress, What It Means to You and Me and How Not to Prevent It. By Henry Grady Weaver. Paper. Price, $1. Pp. 236, with illustrations by Robert F. Irwin. Talbot Books, 6432 Cass Ave., Detroit 2, 1947.

This paper bound pamphlet is a polemic. Mr. Weaver, who describes himself as a businessman, states in a note that he believes certain books should be rewritten and given wider circulation. This he attempts in "Mainspring" with Miss Rose Wilder Lane's "The Discovery of Freedom."

Mr. Weaver has filled his book with many ideas, most of them of the level of the cliché. He falls into the trap of all venturers into a new field—he attributes all things to a single "cause." In his view the only important problem in social relations is the understanding of human energy, which he does not define.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SMALLPOX VACCINATION

To the Editor:—In accordance with Navy practice, I maintain that if the result of vaccination is "primary" (or "take") the patient should be revaccinated seven to ten days later in order to ascertain whether the original vaccination stimulated complete or partial immunity. If the second vaccination results in an "accelerated" reaction, I should revaccinate until an immune response occurs. I contend that all patients who do not show an "immune" reaction should be revaccinated at seven to ten day intervals until an "immune reaction" occurs. My colleagues contend that a "primary" reaction (one vaccination) is adequate for protection. Please discuss.

M.D., California.

ANSWER.—Theoretically your contention is correct that a person who is not susceptible to an attack of smallpox should have an immune reaction when vaccinated with potent smallpox vaccine. Actually the procedure which you suggest is neither practical nor necessary. If an unvaccinated susceptible person is vaccinated within three days of exposure to smallpox and the vaccination is successful it is almost absolutely certain that smallpox will not develop. Instances of this kind have been observed repeatedly in a smallpox hospital.

A successful vaccination in a person who has not been vaccinated successfully at any previous time is termed a "primary vaccination." If vaccination is repeated there should be a reaction of immunity. The duration of immunity resulting from a primary vaccination cannot be foretold accurately. Ordinarily a primary vaccination will afford protection against smallpox from five years to life. A loss of immunity can be determined by obtaining either another successful vaccination or an accelerated reaction. In considering an immune reaction it must be remembered that a proper interpretation rests on the knowledge that the vaccine lymph used in the procedure is potent. A "no take" or failure to secure any reaction from a vaccination should not be confused with an "immune reaction."

SPIDER VARICOSITIES

To the Editor:—Please discuss obliteration of the superficial, spider nevus type of varicosities that some women have on their legs. Is there a satisfactory intradermal injection?

James I. Knott, M.D., San Diego, Calif.

ANSWER.—If the central pool can be found this may be injected; however, others may appear and the results are generally unsatisfactory. Besides, there is danger of sloughing. The experienced operator soon learns to let this variety alone.

INCIDENCE OF CANCER

To the Editor:—What are the latest figures on the incidence of cancer in relation to the organs of the body? On what proof is cancer metastasis based?

Floyd Thurber, M.D., Hollywood, Calif.

ANSWER.—See Reprint 2537 from the *Public Health Reports,* entitled "Illness from Cancer in the United States," by Harold F. Dorn; also see the New York State Department of Health Annual Report, 1944, volume 1.

Cancer metastasis is based on the presence in regional lymph nodes and distant organs of tumor foci having histologic features similar to the primary growth.

REPIGMENTATION OF HAIR

To the Editor:—A diabetic woman aged 74 seems to experience a change in the color of her hair from gray to that normal in her middle age after taking insulin. Are there other such cases on record? She is not taking other medicament and is not using hair dye or rinse.

Elmer W. Clarke, M.D., Norton, Mass.

ANSWER.—Apparent repigmentation of gray hair is observed not infrequently in diabetes mellitus after good nutrition and control of unbalanced sugar metabolism are restored. The reason for it is not known. Theories to account for it are: (1) improvement in nutrition and hydration; (2) correction of avitaminosis caused by diuresis or restriction of dietary intake; (3) restoration of endocrine balance, which has been altered along with the progress of the diabetes, and (4) xanthochromia affecting the color of the hair in much the same manner as it colors the skin a faint orange when diabetic diets are used, possibly by carotene which is not metabolized to yield vitamin A, possibly by deposit of other-pigments such as those contained in butter and cream.

CLINITEST TABLETS

To the Editor:—Is the tablet method ("clinitest tablets," made by Ames Company, Inc., Elkhart, Ind.) acceptable to insurance companies in testing for urinary sugar? Is this method as reliable as using Benedict's or Fehling's solution?

R. C. Sadler, M.D., Whiteville, N. C.

ANSWER.—The use of "clinitest tablets" is approved by a number of the larger life insurance companies. Recently Blatherwick and Dworkin of the Metropolitan Life Insurance Company laboratory (Blatherwick, N. R., and Dworkin, J. H.: A Rapid Test for Albumin and Sugar in the Same Measured Sample of Urine, *J. Lab. and Clin. Med.* **32**:1042 [Aug.] 1947) have suggested the use of these tablets. Kasper and Jeffrey (Kasper, J. A., and Jeffrey, I. A.: A Simplified Benedict Test for Glycosuria, *Am. J. Clin. Path.*, Tech. Sect. **8**:177 [Nov.] 1944) found that the results obtained with the two methods were comparable. Both reagents contain copper sulfate, with the addition of sodium carbonate and sodium citrate in the case of Benedict's reagent and sodium hydroxide, sodium bicarbonate and citric acid in the "clinitest tablets." Sodium hydroxide is the alkali employed in Fehling's solution. The sodium hydroxide has an additional special use in the "clinitest tablets," since the heat for the reaction is provided by its heat of solution. Mixing is brought about by the evolution of carbon dioxide. In an answer to a query in THE JOURNAL (Oct. 10, 1942, p. 491), checks with Benedict's reagent and "clinitest tablets" were reported as good. The user was cautioned against allowing the tablets to come in contact with the skin. If a simultaneous test for albumin is desired an "albutest tablet" (Ames Co.), which contains sodium molybdate, citric acid and a small amount of effervescent base, may first be employed.

PENICILLIN PREVENTIVELY

To the Editor:—There is a practice among surgeons in this area of giving patients a single massive dose (100,000 to 500,000 Oxford units) of penicillin in isotonic sodium chloride solution (not oil and wax) following elective minor surgery with or without general anesthesia. This is used for the prevention of infection and postoperative complications.

How long will a suitable blood level of penicillin be maintained? Will this therapy prevent postoperative infection or is it a waste of penicillin?

M. D., Kentucky.

ANSWER.—A single dose of penicillin, 100,000 to 500,000 units in isotonic sodium chloride solution would maintain a detectable blood level of penicillin from four to six or eight hours. It is highly questionable whether a single dose of penicillin will prevent a postoperative infection. It would be sounder therapy to continue the injections at intervals of eight to twelve hours for three to seven days in order to prevent susceptible infections.

ROENTGEN THERAPY

To the Editor:—How does roentgen therapy in dermatology work? What does it do to the skin and its disease? Is it cumulative in effect, and if so for how long? Can it be recommended in the acute pyodermas?

M.D., Rhode Island.

ANSWER.—Roentgen rays appear to reduce the activity of cells in all their various functions. Just how this is accomplished is still an unsettled question, some attributing it to an ionization effect, others to a coagulation effect on the protein molecule analogous to the action of heat; still another explanation combines features of the two concepts to account for an altered concentration of intracellular and intercellular fluid. Much depends on the dosage. When the dose of rays is small, the cells are not perceptibly influenced. After a larger dose, there is a temporary increase in cellular division and cellular metabolism. Larger doses act to inhibit mitosis and to induce cellular degeneration, the degree of which depends on the variety of cells and the dose of rays, for tissues vary in their response to radiation. This period of depressed cellular activity is followed by a compensatory phase of hyperactivity and then by a return to normal. Radiations, however, are always injurious to cells which absorb them; the effect of repeated irradiation is cumulative, the degree of accumulation depending on the size of the dose and the interval between treatments.

Desjardins explains the effects of radiation on inflammatory conditions by assuming that "radiation by destroying some of the infiltrating leukocytes causes the protective substances in these cells to be liberated and to be made even more readily available for defensive purposes than when they were in the intact cells. This, and the increase in phagocytosis which follows the disintegration of the cells, represents the main effects of exposure to x-rays and irradiation." The majority of cutaneous diseases represents some form of acute or chronic inflammation with varying degrees of leukocytic infiltration, cellular hyperplasia, hyperemia and proliferation of connective tissue, with or without associated products of cellular degeneration. Herein lies the rationale for radiation treatment of certain diseases of the skin, including particularly the deep seated pyodermas.

"LIPIODOL" IN SPINAL CANAL

To the Editor:-The diagnosis of a ruptured intervertebral disk would be made easier in obscure cases if radiography of the spinal canal with iodized poppy seed oil 40 per cent "lipiodol" was safe. Has any one using this procedure ever attempted to remove the injected iodized oil through a caudal anesthesia needle inserted into the sacral canal and intentionally made to penetrate the dura? Then with the patient in Fowler's position the iodized oil could slowly be withdrawn and replaced with sterile saline solution. If this procedure has not been attempted, is there any reason why it would not work, since the heavier iodized oil will settle to the lowermost portion of the spinal canal?

Michael Carlozzi, M.D., Brooklyn.

ANSWER.—Opaque oil has been removed from the spinal canal by puncture of the dural sac through the caudal canal. It has been removed by trephining the posterior wall of the sacrum and aspirating the dural sac or incising the dural sac. These procedures are not necessary, in that the opaque oil can usually be removed through the lumbar puncture needle utilized for the introduction of the oil.

XANTHINE CONTAINING BEVERAGES IN GOUT

To the Editor:—What is the present feeling in regard to the use of coffee in gout or uric acid diathesis, and what is the recommendation with regard to substitution of caffeine-free coffees?

R. B. Hemphill, M.D., Oak Park, Ill.

ANSWER.--Coffee, tea and cocoa have sometimes been eliminated from the diet of patients with gout because they contain xanthine bases which were assumed to produce an excess of uric acid and an increase in tophaceous deposits. Actually, no increase of true uric acid results from the dietary use of these beverages. Early studies on the conversion of methylated xanthines to uric acid were unreliable because (1) experiments were carried out on rabbits and species of dogs whose chief end product of purine metabolism is allatoin, not uric acid, and (2) methods were not available to differentiate xanthine from other urate substances.

It has now been determined that in human beings the xanthine bases of coffee, tea and cocoa are converted by partial demethylation to methylurates. This methylated derivative reacts, as does uric acid, with phosphotungstic acid and silver preparations to form reduction products which are indistinguishable by colorimetric methods of analysis from uric acid. By use of uricase, a method has been developed to measure urinary uric acid in the presence of methylurates. This uricase method has has shown that ingestion of caffeine, theophylline or theobromine does not increase the excretion of "true uric acid"; neither are methylurates deposited in tophi. Hence, coffee, tea and cocoa are allowed in the diet of patients with gout.

BILATERAL CRYPTORCHISM

To the Editor:—A man aged 21 (weight 194 pounds [88 Kg.], height 68 inches [173 cm.]) with bilateral cryptorchism, first became aware of this when in January 1945 the army induction doctors called it to his attention. The testes cannot be felt in the inguinal canal. There are no evidences of hypogonadism and the patient has normal ejeculations. On two occasions examination of the ejaculatory specimen revealed complete aspermia. Is hormone therapy advisable? Is surgery indicated, since the incidence of tumors in ectopic testes is much greater than in normally situated ones?

Milton Canter, M.D., Brooklyn.

ANSWER.—Unless the patient has some evidence of endocrine dysfunction, there is no indication for any hormonal therapy. A bilateral orchiopexy is indicated.

THROMBOEMBOLISM IN CHILDREN

To the Editor:—The problem of thromboembolism is receiving more and more attention. What are the possible explanations for the rare occurrence of this phenomenon in children as compared to adults, particularly in the surgical patients? Give references regarding relative rates of venous blood flow in children as compared to adults.

M.D., New Jersey.

ANSWER.—The rare occurence of thromboembolism in children as compared to adults has probably never been satisfactorily explained. At present the best explanation seems to be on a morphologic basis. Veins, as arteries, develop sclerosis with age. Just as the arteriosclerotic artery develops spontaneous thromboses due to atheromatous plaques and roughening of the intima, this occurs probably in the major veins also and is the best explanation of why thromboembolism is seen in the older age group. As far as can be determined, there is no difference in the coagulability of the blood in the young and the aged. As far as known there are no data on the rate of venous blood flow in children as compared to adults. In patients with severe peripheral arteriosclerosis there is undoubtedly less blood flowing through the veins of the lower extremities, since there is less blood entering the extremities. The incidence of thromboembolism is probably not really higher in the patients with deficient arterial circulation compared with those with normal arterial blood flow.

SYPHILIS

To the Editor:—On May 22, 1946 I examined a man, aged 42, for employment. Results of his examination were negative but the laboratory reported positive responses to Kolmer (Wassermann), Kahn and Kline tests. He gives no history of venereal infection. Tests of his wife, the second, are negative. I started treatment June 7, 1946, giving him weekly treatments as follows: ten injections of oxophenarsine hydrochloride ("mapharsen") 0.06 Gm.; then six of bismuth subsalycilate, 0.13 Gm.; ten of "mapharsen"; ten of bismuth and five of "mapharsen." During this time his Wassermann, Kolmer and Kline tests have remained positive, and after the last two injections of oxophenarsine hydrochloride he had loose stools. Am I warranted in giving this man any more antisyphilitic treatments? He has had twenty months of continuous treatments.

M.D., Iowa.

ANSWER.—It is unfortunate that in the beginning you did not get a titered serologic test on this patient and then follow him along with a monthly titered test. Moreover, there is even a possibility that this man may have a false positive reaction. One should always be suspicious of low titered reactions. A lumbar puncture should have been done in the beginning but may still be done; be sure that there is no involvement of the central nervous system. He may have an asymptomatic syphilis of the central nervous system. Only after all these precautions have been taken would it be possible to properly evaluate this patient's true situation.

If his lumbar puncture reveals that he has involvement of the central nervous system, it would be well to hospitalize him and give him crystalline penicillin G intramuscularly, 40,000 units every three hours, day and night, for three weeks. On the other hand, if his lumbar puncture reveals normal conditions and if careful examination of the cardiovascular system disclose nothing, it would be considered that the patient has a late latent syphilis and that further treatment is unnecessary.

Heavy metal therapy is more and more looked on with less favor than penicillin therapy. It is true that there are situations in which the former may be used as an accessory treatment, but first dependence is placed on penicillin.

INDICATIONS FOR THERAPEUTIC ABORTION FROM THE POINT OF VIEW OF THE SURGEON

SAMUEL C. HARVEY, M.D.

New Haven, Conn.

The instances in which the surgeon who does not practice in the field of gynecology has to consider the indications for therapeutic abortion or other interference with the anatomic and physiologic components of pregnancy are few. So much is this the case that no one person is likely to accumulate an experience and knowledge in this subject at all comparable to that of the obstetrician and gynecologist. Nevertheless, the surgeon may at any time find himself in a situation where the well-being of the pregnant mother or the fetus or both are imperiled and a crucial decision must be made.

This may be the case with certain surgical diseases which are urgent or of an emergency nature and require immediate operative intervention in order that both mother and child not succumb, even though this may entail some risk of an abortion. Examples of these are intestinal obstruction, perforation of the intestine, acute appendicitis and massive hemorrhage. Other diseases for which the ultimate therapy is operative, but in which the danger is neither immediate nor great, may be handled conservatively until normal delivery occurs, or at least until a viable fetus can be obtained. In instances of these, as hernia of the abdominal wall or hemorrhoids or varicose veins, the mother may suffer discomfort but no damage from delay. Only rarely and under indications not purely surgical would a therapeutic abortion be advisable in these various situations.

Certain common chronic diseases amenable to surgical therapy may cause some minds to weigh the question of therapeutic abortion, only to dismiss it on serious consideration. As an example, the coincidence of thyrotoxicosis and pregnancy is not unusual and is best treated as it would be were it not complicated by pregnancy, or rather as it would have been before the introduction of thiourea and thiouracil. This last reservation is made until further study has determined the effect, if any, of these drugs on the fetus. In any case, to introduce abortion in a patient with hyperthyroidism would be asking for trouble, and were it necessary for other reasons the toxicity should be obviated by medical or surgical means as indicated in the particular patient, before it is attempted.

Another even larger group of diseases is that of malignant new growths and, of particular pertinence to this discussion, the carcinomas in the female. Those associated with the female organs specifically concerned with reproduction, namely the genitalia and the breasts, comprise approximately one half of the morbidity and mortality in the female of what is commonly known as "cancer," the frequency being divided between the two with a small predominance in the breast. It is with the latter that the surgeon is concerned in this discussion, and particularly when carcinomas of the breast are concurrent with pregnancy or lactation.

Fortunately, this association is relatively rare and for several reasons. Only approximately one third of these tumors of the breast occur during the age when nearly all pregnancies take place, namely from puberty to 45; a second third from 45 to 55 is associated with the menopausal changes, and the last third with the involution that goes on with aging.[1] Of the 4,628 patients operated on for carcinoma of the breast and reported by Stewart W. Harrington,[2] there should have been about 1,500 instances in the child-bearing age when the association with pregnancy might be expected to be frequent. The number and distribution of pregnancies in this group was not known, but there were 92 instances of carcinoma of the breast associated with pregnancy or lactation, or about 2 per cent of all the operations, or approximately 6 per cent of those that may be expected to have been below 45 years of age, in all probability indicating a relatively lower incidence of this lesion in pregnancy and lactation than in those women not carrying a child. This agrees of course with the well established understanding that carcinoma of the breast is more frequent in the nulliparous. However, as Grantley Taylor has shown, while the incidence is not increased in young women, the degree of malignancy is, as indicated by the fact that metastases occur earlier and to a greater degree and that therefore postoperative recurrences take place more promptly. This same situation is exaggerated in the pregnant woman as indicated by Harrington's data,[2] according to which in 88 instances of radical mastectomy for carcinoma during pregnancy or lactation 85 per cent had spread beyond the breast and only 15 per cent not. The survival rates in those having axillary metastases were, at three years, 17.3 per cent and at 5 years 5.5 per cent, while for those with the growth confined to the breast the rates were 65.5 per cent at both three

[2] Harrington, S. W.: Carcinoma of the Breast: Results of Surgical Treatment When the Carcinoma Occurred in the Course of Pregnancy or Lactation and When Pregnancy Occurred Subsequent to Operation (1910 1933), Ann. Surg. **106**: 690-700, 1937.

and five years. Whatever significance this may or may not have as regards therapeutic abortion, it does indicate that the obstetrician and surgeon during pregnancy should examine the breasts frequently and carefully in the hope of detecting a tumor early, when it may be still confined to the breast. If it proves to be malignant, then a radical mastectomy must be done.

Only when these data are at hand should a decision be made as to an abortion. It is clear, as Grantley Taylor[3] has pointed out, in young women that once the malignant lesion is established, therapy of any nature will not change its biologic characteristics, and I think one may include in this the removal of the fetus and placenta. Certainly when there is a spread beyond the "breast" it would be illogical to destroy one life in order to attempt to retrieve a nearly hopeless situation in the parent, particularly in view of the fact that there is no evidence that doing this would in any way change the course of the disease. When the growth has not extended beyond the breast, probably indicative of its relatively lower malignancy, and when the outlook is much more favorable, there is still less reason to terminate the pregnancy, and particularly if it is beyond the third month. There may be adequate reasons for doing so previous to this time, other than malignant disease, but these do not fall within the province of the surgeon.

As regards nursing the baby, it is largely an academic question, for with one breast removed it is unlikely in these days that the remaining breast will be so employed. In fact, it is not certain that it is either beneficial or dangerous. In any case, during pregnancy and lactation it is necessary to follow closely the residual breast, for under these conditions the frequency of involvement is probably somewhat increased.

As regards pregnancy following a radical mastectomy for carcinoma not occurring in conjunction with pregnancy, Harrington's[2] experience is of interest. There were 55 such instances, of which he was able to follow 37. Of these patients 33 lived one or more years after the birth of the baby, and, of the 12 patients who had live babies fifteen or more years previously, 7 were living. He advised those having had carcinoma of the breast not to go through further pregnancies, and if they had children not to nurse them. In fact, there is not sufficient factual information to be certain that this advice is necessary. On the other hand, it might be well for the patient to avoid pregnancy for three or four years subsequent to a radical resection, in order to obviate the possible simultaneous occurrence of a pregnancy and a recurrence. So far this discussion because of its bearing on therapeutic abortion has been governed by the "curability" of established carcinoma of the breast, which involves, so far as is known at the present time, the detection and destruction of the primary focus before spread has occurred. Once this is accomplished, further measures are unnecessary, but if the disease is elsewhere, then the treatment is palliative, in the hope of slowing up its progress and of ameliorating the distressing symptoms. While a "cure" should always be striven for and is an end devoutly to be desired, at the present time in the majority of instances of carcinoma of the breast it still remains true that the therapy is palliative.

For many years it had been suspected that changes of the breast were dependent on ovarian function. With the discovery and intensive study of the estrogens and of their effect on the development of the breast in the experimental animal, particularly the production of "cancer of the breast" in the male mouse of a tumor-susceptible strain, the hope of effecting a cure or of producing palliation by the cutting off of estrogens, or by their "neutralization" with the androgens, has come to the fore. That the former can be accomplished seems extremely unlikely in view of present knowledge, for, as Nathanson[1] said, "the estrogens in themselves are not carcinogenic, but merely provide the substrate upon which an exciting agent may act." Furthermore, while they may have a great deal to do with the initial change from benignity to malignancy, once the growth becomes autonomous and is capable of growing on heterologous transplantation in either male or female animals, it is obvious that changes in either estrogen or androgen are unlikely to destroy it. Nevertheless, the ablation of the testicles or the administration of estrogens in carcinoma of the prostate as initiated by Huggins has demonstrated in many instances at least definite palliation.

Consequently, at the present time there is a recurrent interest in the "sterilization" of the female with carcinoma of the breast, by radiation of the ovaries or by their ablation when cessation of menses has not occurred. As long ago as 1905 Hugh Lett[4] in England reported 99 instances of "incurable carcinoma of the breast in which bilateral oophorectomy was done; with marked improvement in 22 and distinct improvement in an additional 35." These beneficial results he described as "relief of pain, improvement in health, diminution or disappearance of growth, healing of ulcers and prolongation of life." He was probably over-optimistic in his interpretation, and others who followed his lead did not obtain so good results or became discouraged at palliation, which in the end arrived at the same ultimate result.[5] Similar findings are now being obtained in perhaps a third of those patients who are suffering from pain due to metastases to bone. In addition to the cutting down of the production of estrogen in this manner, which is by no means complete, the use of testosterone[6] is being tried out, with apparent beneficial results in some instances.

These attempts at hormonal therapy are as yet experimental and directed at palliation of existing disease. There is no indication at the moment that they will effect "cures" or prevent cancer, and, indeed, in careless hands it is possible that they may do more damage than good. It would be better to leave their use to those having adequate clinical material, sufficient knowledge of these hormones and critical judgment, until the proper indications and methods of application are fully developed.

Thoracolumbar Sympathectomy.—The surgical treatment of hypertension had its origin in the pioneer work of Crile, Adson and Craig, Page and Heuer, Peet and others, but it was not until 1940 when Smithwick first reported his clinical studies that an efficient operative procedure was made known.—Hinton, J. W.: *Bulletin of the New York Academy of Medicine*, April 1948.

THERAPEUTIC ABORTION FROM THE POINT OF VIEW OF THE INTERNIST

HORACE M. KORNS, M.D.

Dubuque, Iowa

From the point of view of the internist, diseases of the cardiovascular system far outweigh any other possible indications for therapeutic abortion. This is a corollary of the fact that pregnancy tends to increase both cardiac output and blood volume. As Burwell[1] has observed, pregnancy produces cardiodynamic changes similar to those which characterize arteriovenous fistula. Within certain limits, these changes are reversible in both instances.

Let us first consider hypertension which grows steadily worse as pregnancy proceeds. This includes hypertension which existed prior to conception, as well as that which appears during gestation. Certain observations[2] have indicated that many women with hypertension, even when they have albuminuria, edema or headache, bear children without immediately discernible ill effects to themselves or their offspring. In such cases, however, the probabilities are that the hypertension is fundamentally benign and that it will abate to a considerable extent after delivery. It is another matter when the diastolic pressure manifests an ever increasing upward tendency, especially during the first trimester. Hypertension of this variety, with a diastolic level rising above 110 mm. of mercury, must be considered actually *or potentially* malignant, and therefore should constitute an indication for abortion. This indication becomes imperative as soon as impairment of the function of either the heart or the kidneys can be demonstrated.

It is well known that women with old cardiac valvular lesions, including mitral stenosis, often bear one or more children uneventfully. In these cases the lesion must be minimal from the dynamic point of view, or the patient must have lived such an elaborately sheltered life that having a baby was the only real work she ever did. In deciding which patients with valvular heart disease should be allowed to go to term, one must consider the age of the patient, how much cardiac hypertrophy she has, evidence of congestive heart failure, past or present, and the mechanism of the heartbeat.

Age need not be discussed, for it is obvious that, other things being equal, the younger the patient, the better her chances.

The amount of cardiac hypertrophy is particularly important. Generally speaking, hypertrophy develops in direct proportion to (1) the degree of mechanical embarrassment produced by the valvular lesion and (2) the extent to which the myocardium was involved in the original inflammatory process. This generalization, however, is beset with disconcerting exceptions which tax the resourcefulness of the cardiologist. Chief among these is the conjunction of a mechanically severe lesion with minimal hypertrophy. If, in addition, the auscultatory signs are misleading or wanting, the disease is virtually undiagnosable by ordinary clinical methods and recourse must be had to special procedures which cannot be described here.

In all cases in which ventricular hypertrophy is present, the amount of the hypertrophy is much more important than the valvular lesion, regardless of its severity or location. It is impossible to overemphasize the old observation that the greatly hypertrophied heart is a severely damaged, and therefore a seriously weakened, heart. Cardiac hypertrophy not only encroaches directly on the myocardial reserve, but also greatly diminishes the efficiency of the heart by increasing the amount of cardiac residual blood. This increase may amount to as much as 1,000 to 1,200 cc., which means, of course, that each systole can do no more than skim the surface of the pool.

The pathologist quickly ascertains the degree of cardiac hypertrophy by weighing the heart, but the clinician must rely on indirect methods. If, in the absence of congestive failure, the heart is demonstrably enlarged, hypertrophy is presumably present, but this is strictly inferential, and, if the hypertrophy is more concentric than eccentric, its extent will always be underestimated. Furthermore, simple hypertrophy alone probably constitutes less of a hazard to the patient than hypertrophy plus an increase in cardiac residual blood. Therefore, in order to improve the clinical estimate of the degree and kind of hypertrophy and to ascertain as accurately as possible the amount of cardiac residual blood, careful measurements of the arm to tongue circulation time must be made. Discounting *the changes in circulation time caused by pregnancy* itself, the greater the prolongation, the larger the risk.

Congestive heart failure which tends to progress in spite of treatment and is characterized by an increase in systemic or pulmonary venous pressure, or both, constitutes a clearcut indication for therapeutic abortion, regardless of whether the failure antedated the pregnancy. If the patient has had congestive failure in the past, as attested by the history, permanent cardiac enlargement and enlargement of the liver, without hepatic pain or tenderness, pregnancy may be allowed to proceed only if extraordinary precautions are taken and the patient is kept under close observation. Some patients with a chronic, nonprogressive form of heart failure, in which there is no increase in venous pressure and moderate edema is the principal manifestation, often tolerate pregnancy surprisingly well.

Some of the disturbances in the mechanism of the heartbeat are dynamically or symptomatically so serious and so intractable that they may constitute an indication for therapeutic abortion. Included among these are acquired auriculoventricular heart block and bundle branch block, and chronic and paroxysmal auricular fibrillation, auricular flutter and ectopic tachycardia, particularly ventricular tachycardia. If the patient also has chronic valvular heart disease, the indication often becomes *urgent. Congenital* auriculoventricular heart block or bundle branch block, if unaccompanied by other lesions, introduces no maternal risk whatsoever.

If acute rheumatic heart disease or subacute bacterial endocarditis develops during pregnancy, the indication for abortion is imperative and immediate, despite the fact that, in the case of the latter, modern chemotherapeutic methods often effect a cure. Fortunately, the incidence of these diseases during pregnancy is extremely low

Before leaving the subject of cardiovascular disease as an indication for therapeutic abortion a few ghosts which seem to survive only in textbooks of obstetri

---

Read in a Panel Discussion on Modern Indications for Therapeutic Abortion before the Section on Obstetrics and Gynecology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

1. Burwell, C. S.: The Placenta as a Modified Arteriovenous Fistula Considered in Relation to the Circulatory Adjustments of Pregnancy, Am. J. M. Sc. 195: 1, 1938.

2. Sharkey, J. A., and Hess, C. B.: The Effect of Essential Hypertension on Pregnancy, Am. J. Obst. & Gynec. 52: 672, 1946.

should be laid. There is nothing to substantiate the assertion that the maternal heart undergoes hypertrophy as a result of pregnancy, as any internist who has examined many mothers of many children knows well. Dilatation of the right ventricle occurs under certain circumstances, but it has nothing specifically to do with pregnancy. A pulsation in the veins of the neck is normal when the patient is recumbent. If it occurs in the sitting position, it indicates an increase in systemic venous pressure, which is one of the signs of congestive heart failure. This subject has already been discussed. Geographic location is unrelated to the incidence of rheumatic heart disease, as Army and Navy reports have shown. It has often been said that many pregnant women have "functional" heart murmurs. If a murmur did not function, it could not be heard, and therefore all murmurs are "functional," but some which appear to be endocardial are extracardial. Making the distinction is a problem for the student of physical diagnosis, not for the accoucheur. Finally, digitalis is not indicated in all cases of heart disease or heart failure and must not be prescribed indiscriminately.

In cases of pulmonary tuberculosis, pernicious anemia and diabetes mellitus, abortion may occasionally be indicated, but not as a rule, for the treatment of these diseases is now so successful that pregnancy may safely be allowed to proceed to term. Severe hepatitis or ulcerative colitis may make abortion advisable, but diseases such as leukemia, lymphoma and polyneuritis obviously do not.

PANEL DISCUSSION ON MODERN INDICATIONS FOR THERAPEUTIC ABORTION

S. A. Cosgrove, M. D., N. J., Moderator

Dr. Catherine MacFarlane, Philadelphia: I was much interested in Dr. Harvey's discussion of the need for therapeutic abortion in women with cancer, particularly with cancer of the breast. I was reminded of Dr. Bittner's demonstration some years ago of the milk factor as an agent in the transmission of cancer in strains of susceptible mice. Applying this to women, it would seem that complete elimination of nursing with cancer of the breast or other organs would be indicated. Perhaps this procedure would eliminate the necessity for considering the production of abortion in these women who happen to be pregnant and also have cancer of the breast.

Dr. Marie Pichel Warner, New York: The woman physician is besieged with more requests for abortion for real or imagined therapeutic indications than the male physician. There are many cases in which the indications for therapeutic abortion are not clearly defined. What, for example, should be one's attitude in advising a patient who requests a therapeutic abortion because she had suffered from a depressive state for which she had been institutionalized and had been treated with shock therapy? A normal woman has a strong maternal drive. Is it not possible, then, that the very fact that a woman appeals to a physician for therapeutic abortion is an indication of sufficient mental and emotional imbalance to warrant a therapeutic abortion followed by psychotherapy? The mental reaction and future of the unmarried pregnant woman in terms of personal shame and disgrace to the family, when she is forced to have a child which she places for adoption, should be the subject of serious consideration as a psychiatric indication for therapeutic abortion. There is at present no satisfactory solution to this problem. There is also the problem of the woman of menopausal age who becomes pregnant. She may not have a serious organic indication for therapeutic abortion, but psychologically develops a severe anxiety state about her middle age. When strong fears exist regarding the outcome and delivery at middle age, and her feeling of inability to handle an infant and a belief that her age restricts a normal parent-child relationship, what should be advised? The saddest cases are those of married women who are not yet ready to have babies for economic or other reasons. They have an illegal abortion and then soon after, because of the psychologic reactions, are driven to desire a pregnancy and find that they have become sterile after the recent abortion. One tends to think of the child in all these cases, but still one owes something to the woman. At least, one should try to help her constructively and not just evade the question by saying, "I'm sorry, I can't help you. Go elsewhere. You have to do the best you can. Abortion is illegal." All of these replies are not helpful. I should like more constructive advice and help with the problem of handling the case of the single girl who is in the early months of her pregnancy. The prevention of illegal abortion with its concomitant maternal morbidity and mortality can be helped best by broadening and liberalizing the interpretations of medical indications to include the social and mental hygiene problems of each particular case. Sex education, a biologic understanding of conception and premarital marriage information are preventives for unplanned pregnancies, which eliminate the question of abortion, both therapeutic and illegal.

DEPRESSIVE STATE

Dr. E. W. Busse, Denver: Dr. Warner's questions concern problems which physicians frequently encounter and on which they are asked to make decisions. The first case which Dr. Warner cited was of a young girl who had a depression, was given electric shock therapy, is now illegitimately pregnant and wants an abortion. This is a case which rests on the careful evaluation of the patient by the psychiatrist for the simple reason that he first must decide how severe this depression is or was. For instance, at the institution with which I am associated we do not ordinarily believe in giving electric shock therapy to patients with psychoneurotic depressions. Some psychiatrists do. If it were merely a neurotic depression, I would not recommend a therapeutic abortion. However, if the depression was a recurrence and was rather severe, and if the pregnancy allowed to go to term would prevent her eventual recovery, I would recommend a therapeutic abortion.

THE ECONOMIC FACTOR

The second problem presented involves a woman who comes in wanting an abortion, stating that she is not economically ready to have a child. This is not a question for the physician to decide, whether a person is economically able or not. An abortion is certainly not justified. Some persons want a lot more financial security than do others before starting a family. A psychiatric problem is frequently present when a person asks for an abortion and gives as an excuse poor economic conditions. I believe it is best to talk not only to the potential mother but also to the husband and to find out where he fits into the picture. It is often the husband who is at fault, insisting on an abortion. He may be a poorly adjusted person, and if he can be helped a difficult marital situation may be improved.

INCEST

Question: What would be your attitude and the attitude of your committee in a case of incest?

Question: One of my patients had a daughter who was impregnated by the father.

Dr. Busse: I would probably recommend a therapeutic abortion. It has been my experience that a girl who is in such a situation, where the father will force her into sexual activities, is in an extremely poor home environment. That child is often a candidate either for a psychosis or for a life of antisocial behavior. Final opinion, of course, would rest on the child's mental condition, but often a therapeutic abortion is justified. The patient should have the benefit of psychiatric care, to do something about her future and to prevent a major mental illness.

RAPE

Question: Would that situation apply also to rape?

Dr. Busse: I believe that the justification of therapeutic abortion depends on the patient's mental condition and her attitude regarding her unwanted pregnancy.

MENOPAUSE

Question: What about the woman in menopause? Don't you think that the woman is afraid not because she is pregnant but because of the fact that the neighbors will talk about her since she is 43 or 45 years old and is pregnant? Don't you think that by means of radio, education, newspapers, etc., a woman could be helped to hold the baby?

Dr. Busse: The point has been raised that if a woman is going through the menopause, or is near it, and becomes pregnant she frequently worries about how the neighbors will feel and wonders what to do about it. Certainly proper education by any means is desirable. I certainly would not, off hand, recommend a therapeutic abortion unless the patient is faced with a psychotic break from which she might never recover. Otherwise, I do not believe that I would be justified in doing anything, especially if she has been a perfectly well integrated person up to that time.

GERMAN MEASLES

The Moderator: A number of inquirers are specifically interested in the recently much discussed necessity for therapeutic abortion in mothers who have had German measles in the early part of their pregnancy.

Member: I think there is a bit of confusion. It is chickenpox, not German measles.

The Moderator: German measles; several have inquired about that. I myself cannot answer that question. I feel that we have too quickly gone overboard on the inadequate evidence that has been accumulated thus far as to what proportion of women suffering from German measles early in pregnancy are going to have defective offspring. Until that question is answered by a greater accumulation of experience, I am afraid that none of us can answer the question as to the necessity of abortion for every woman who has German measles during the early part of her pregnancy. That is an inadequate answer, but it is the only answer that I feel competent to make at this time.

VACCINATION

Question: Recently in New York city, in connection with the epidemic of smallpox, the Health Department was asking whether women in early pregnancy should be vaccinated. The Health Department decided not to vaccinate during early pregnancy for fear that these women might possibly have defective children.

The Moderator: There has recently been in the New York metropolitan area not an epidemic but several sporadic cases of smallpox which have been fatal. The Health Department of the city and state thereupon properly seized upon that circumstance in an effort almost to coerce the population into widespread vaccination. Every pregnant woman within 50 miles of New York City Hall wanted to know about the advisability of vaccination. Inasmuch as German measles is a virus disease, many physicians thought that if a woman is inoculated with another active virus the effect on her offspring might be similar to that which is supposed to result from German measles. Many physicians, including myself, advised their pregnant patients to have it done. The Health Department did not have the courage to make it obligatory on such women. I think that within the next two or three years the results will be available of what constitutes a great mass experimentation in regard to this matter which no one has heretofore had opportunity to observe. We should all anticipate the conclusions to be drawn from the observations of that great mass experiment.

BUERGER'S DISEASE

Question: Should abortion be induced in a woman with Buerger's disease?

Dr. H. M. Korns, Dubuque, Iowa: Buerger's disease is extremely rare in women, but, if this question should arise, it could not be answered without careful study of the entire cardiovascular system, for Buerger's disease often involves visceral, as well as peripheral, arteries and veins.

THERAPEUTIC ABORTION CAUSE OF STERILITY

Moderator: What about the woman who has procured a therapeutic abortion, the indication for which is not specified, who thereafter is unable to conceive and becomes desirous of having a child? I think that Dr. Busse touched on that in his original discussion. Do you want to elaborate on it, Dr. Busse?

Dr. Busse: I will go over that question as I understand it. I may be wrong. The woman had a therapeutic abortion and thereafter wanted a child but was unable to conceive. What is going to happen? Such a woman may develop guilt feelings and become depressed and suicidal. These patients are difficult to handle. Frequently the psychiatrist has no way of treating them other than use of electric shock therapy. After the depression has begun to improve, then it often becomes a matter of prolonged psychotherapy. In the cases of less severe depression it is sometimes possible that the patient will eventually become capable of accepting an adopted child as a substitute. However, that is an individual problem, and I am afraid that I cannot generalize because each patient must be separately evaluated.

The Moderator: I think that all the essayists have sufficiently developed the important point that every case in which therapeutic abortion is proposed must be carefully individualized. Some of the questions cannot be answered categorically, inasmuch as individual considerations would vary greatly.

HYPERTHYROIDISM

Question: A patient a year ago had a thyroidectomy for hyperthyroidism. She quieted down and had a perfectly normal basal metabolic rate after the thyroidectomy. Within a year she became pregnant. After she became pregnant there was a recrudescence of her hyperthyroidism with a high basal metabolic rate comparable to that which she had prior to the operation.

Dr. S. C. Harvey, New Haven, Conn.: It is not unusual to have hyperthyroidism in conjunction with pregnancy. My reaction to it would be exactly as I have said previously, that that patient should be treated as if she were not pregnant, by medical means. If you induce an abortion, you are likely to precipitate the thyroid storm and have much more difficulty with the thyroid situation as a result of the abortion.

TUBERCULOSIS OF BLADDER

Question: A patient whose ureters have been transplanted because of tuberculosis of the bladder is now four months pregnant, and has an attack of pyelitis. Should abortion be induced? She has no children and would like to have one.

Dr. Harvey: That is distinctly a situation that has to be decided with all the factors in hand. Certainly a person who has so severe tuberculosis of the bladder as to require transplantation in all probability has tuberculosis of the kidneys, also. The pregnancy would be a rather dangerous business. On the other hand, if she wishes to take the risk and insists on it, that, after all, is her own decision.

The Moderator: Emphasizing what Dr. Harvey has said, although in this situation even the urologist would not apply urethral drainage in the same way as he would in a normal woman, there is still enough resource in the use of antibiotics and other modern drugs to keep her pyelitis under control, so that it would seem to me worth while at least to attempt to save for her this baby.

TOXEMIA

Question: A patient is 41 years old. She had had her first pregnancy at 33. She had toxemia at the seventh month in that pregnancy, characterized by porphyrinuria, hypertension and edema. She was allowed to go to term and delivered a healthy baby. In her second pregnancy at age 38 she had toxemia with similar symptoms but beginning earlier, this time in the fifth month. She was carried through that pregnancy also by four months of continuous bed rest, survived the pregnancy and was in good health. Her baby lived. Now, at 41, when she is only two months pregnant, she again shows toxemia characterized by headache and a blood pressure of 160 systolic and 110 diastolic. What should be done in this case?

Dr. Korns: I think that the obstetrician could help answer that question. I would have to examine the patient and form an estimate of her myocardial reserve. I have seen such patients, however, who I thought could continue with the pregnancy safely if they were closely watched.

The Moderator: I am glad to see that Dr. Korns, assuming that this woman did not have any pronounced cardiac impairment or impairment of renal function, would be moderately encouraged to attempt to carry this woman through her pregnancy, even though the toxemia has appeared so early. That refers to some of the things which he said in his paper about hypertension per se. I certainly concur with him and would be glad to attempt to carry this patient through to a third successful termination.

RH INCOMPATIBILITY

QUESTION: A patient has lost 2 infants—presumably because of Rh incompatibility between husband and wife. What is the prognosis in this situation?

DR. HUDNALL H. WARE JR., Richmond, Va.: We had had the experience of seeing a patient who lost her first baby, apparently from an Rh incompatibility. The second baby was born alive and lived. The third baby again was lost through an Rh incompatibility. The patient's husband was Rh positive and heterozygous as determined at the third pregnancy, and the wife was Rh negative. In the fourth pregnancy a rather severe toxemia developed at the seventh month with edema and elevation of the blood pressure, but no urinary changes. She was put to bed and her condition improved. She was carried to term and delivered of a living baby this time. In commenting on the case which Dr. Cosgrove has referred to me, I recognize that Dr. Levine and Dr. Diamond, both authorities on this subject, do recommend for abortions certain selected patients who have had proved Rh incompatibilities. Studies to determine whether the husband is heterozygous or homozygous would be helpful. I would try to carry this patient to term if her condition remained good, hoping that she might be one of the lucky ones. I would have her blood examined regularly and watch for an increase in the antibody titer. I would consult one of the experts on Rh studies for advice in treating the patient.

MULTIPLE SCLEROSIS

QUESTION: Should abortion be induced in the patient with multiple sclerosis? She is now in the midst of a four year remission, is 32 years old and is apparently in good health.

DR. BUSSE: In my brief experience, patients with multiple sclerosis are apt to have an exacerbation during pregnancy. I would base my decision on the severity of the condition and the period of time which has elapsed since the last exacerbation. If the patient's symptoms are mild and she is anxious to have the child, I can see no reason for terminating the pregnancy. If she is rather ill and it is probable that the pregnancy will make her condition worse, I would recommend a therapeutic abortion.

THE MODERATOR: A colleague in a nearby city has just successfully brought such a patient through her pregnancy who had no relapse during pregnancy and no sign of deterioration, after the faculty in the local medical college had refused to take the responsibility of carrying her through. Again there is the need for individualization and care in acting too much on strictly didactic principles.

TUBERCULOSIS IN HUSBAND

QUESTION: A man, bedridden with tuberculosis, gets his wife pregnant. She is the only one to take care of him. Should an abortion be induced?

THE MODERATOR: No; as an obstetrician I refuse to be the habitual mechanician of fools who are too selfish and ignorant to take care of themselves.

SPOTTING

QUESTION: How does the panel feel concerning the interruption of pregnancy because of frequent spotting during the first trimester? Many subscribe to the theory that the bleeding may be a natural effort to rid the patient of pregnancy with defective germ plasm and subsequent defects are proved by the condition of the baby.

QUESTION: Let's go a little further and say these patients have had two successive pregnancies, with malformation of the fetuses, hairlip or hydroencephalus. We have had four requests in the past year for therapeutic abortion for such patients. Let's go further and ask whether a patient has had two successive malformations—not one, because it is known sometimes that the next will be a perfectly normal baby, but two—should we consider a therapeutic abortion at their request because they do not want to go through with the third pregnancy?

THE MODERATOR: I do not think so. I have seen such patients repeatedly have perfectly normal babies. One never knows what kind of baby he is destroying when he does an abortion. It may be the best baby that patient has ever had. He has no means of knowing.

My answer to that would be categorically no.

CESAREAN SECTIONS

QUESTION: How many cesarean sections should be allowed before a therapeutic abortion should be done?

THE MODERATOR: Well, what a foolish thing it is to do a therapeutic abortion just because a woman has had two or six or ten previous cesarean sections. Let her go ahead and have this further one by section. Sterilize her then, if you like.

SUMMARY BY THE MODERATOR

There is a phase of this situation that none of the discussers touched on, which is important. Both Dr. Korns and Dr. Harvey have indicated that in spite of the number of situations in which they recognize the necessity for therapeutic abortion, women with all kinds of impairments, in their experience, can be carried safely through pregnancy, no matter what the precise nature or degree of severity of the symptoms which may present themselves, if one can give them extremely careful medical and surgical attention. Medical and surgical treatment costs money. The vast majority of these patients who could afford the costs of an ordinary parturition cannot afford the cost of four to six months' hospitalization. They do not all live in great metropolitan centers where the public hospitals can subsidize that cost through facilities already provided out of tax funds. Eleemosynary sources are not available or are inadequate to do it. And yet, if medicine is going to do its job, if it is going to conserve human life unborn with just as much assiduity and conscience as it devotes to conserving adult human life, a means must be found to subsidize the patient with rheumatic heart that has to be kept in bed, for instance, all during pregnancy. We have a broad problem attending this matter of the conservation of fetal life; that is, the provision of subsidy from public funds at some level—municipal, state or federal—for persons suffering from numerous complications of pregnancy, in the same sense that the campaigns against tuberculosis, syphilis, poliomyelitis and cancer are being subsidized by governmental funds in addition to great voluntary popular subscription. Rheumatism and rheumatic heart disease particularly are next on the list of the great scourges of mankind that will have to be so subsidized. Call that state medicine, if you will; I do not care; I have long since learned not to shy too much at the bugaboo of state medicine, because we have state medicine with us in a large degree and have had for half a century. But if we are going to answer this whole question satisfactorily, the sufferers from many of these diseases must be helped, and the only source of help that I can envisage as available to them on a large scale is public money. It is the duty of this Association to give serious thought to the means of seeing that that great want is supplied. I should like to summarize in a personal fashion, without any reflection on the opinions of these fine men who have provided us with so much worth while thoughtful material this morning. The medical profession from the nature of its work and obligation is and must continue to be a highly ethical group. A high sense of this ethical obligation must be thoroughly instilled in members of the medical profession during their undergraduate experience. The responsibility for this ethical training resides in medical teaching faculties. This responsibility entails organized, positive efforts toward its fulfilment. Nowhere does this ethical sense have more direct bearing than in relation to abortion. Widespread and indiscriminate abortion is a major factor in puerperal mortality. It is believed to be best controlled by retention of the ethical recognition that the fetus is a human being with all the potentialities of every human being; that its destruction is murder, only justifiable in the most extreme circumstances involving direct and imminent threat to the mother's life; that corollary improvement in the whole situation must depend on the wide development of one of the four freedoms given as the goal of our national development, that of freedom from want, and that in the preservation of the ethical sanctity of fetal life and the development of this freedom in all its phases lies more hope of eventual betterment of the general abortion abuse situation than a reversion to the amoral and unethical plane of the most primitive and debased societies. It is the duty of medical bodies to formulate and supply a specific code for the ethical guidance of the members of our profession in relation to this problem.

HEALTH SERVICES FOR THE RURAL CHILD

Availability of Hospitals, Physicians and Dentists in Service Areas

JOHN P. HUBBARD, M.D.
MARYLAND Y. PENNELL, M.SC.HYG. and
ROLLO H. BRITTEN, M.A.
Washington, D. C.

The "National Health Program" of the American Medical Association states that "every child should have proper attention, including scientific nutrition, immunization and other services . . ." Those members of the American Medical Association who have special interest in the field of child health and who belong to the American Academy of Pediatrics have, through an official statement of the Academy, endorsed a similar objective of better medical care and health supervision for all children. Not only private medicine but government and farm groups as well are committed at national, state and community levels to an objective of more and better health services for the rural child.

Convinced that physicians, who are caring for children in their daily practice, must assume a greater share of the responsibility for planning for the improvement of child health, the Academy has undertaken an active program to provide better and more evenly distributed health services for all children irrespective of race, economic status or geographic location. As a first step, the Academy set out to learn the facts concerning existing health services for children so that, with a full knowledge of present conditions, well considered opinions and recommendations might be reached.

A nationwide study of child health services was therefore instituted with the cooperation of the United States Public Health Service and the United States Children's Bureau. During the course of this study, which is now nearing completion, an intensive survey has been made of hospitals, private practice of physicians and dentists, community health agencies and the pediatric training given by medical schools. Much of the information has been collected by personal visits to hospitals, health centers and medical schools. Mail questionnaires to physicians and dentists have brought an exceptionally high percentage of response. The study has been both broad in scope and detailed in its investigation. At the national, state and local levels, facts have been gathered with a definite purpose in mind: to provide the tools with which to improve child health, not only for the country as a whole but for every local community. Therefore, certain of our data are being tabulated for each of the 3,076 counties.

SERVICE AREAS BASED ON COUNTY GROUPS

Inequalities are known to exist in health services for the rural child in comparison with those for the urban child. We undertook to determine the extent and nature of these inequalities in specific detail. But at the outset we accepted the fact that the usual differentiation between rural and urban is unsatisfactory for comparisons in medical services. Many persons living in rural areas are at the same time near enough to urban centers to permit easy access to the facilities of those centers. However, in rural areas far removed from urban centers, services received are, for the most part, restricted to those which can be obtained locally.

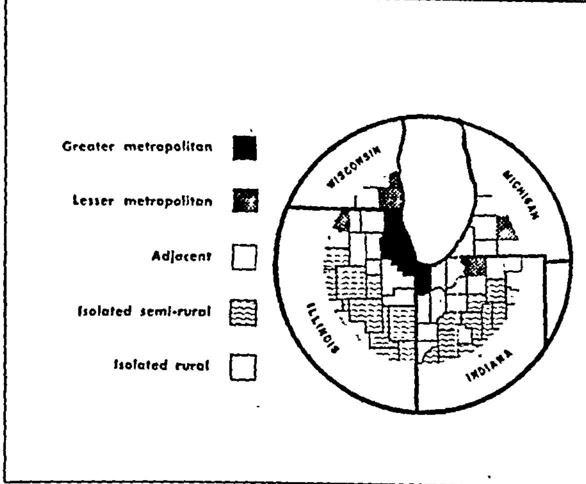

Fig. 1.—Example of county grouping.

Therefore, service areas have been established recognizing two fundamental characteristics: *(a)* population and *(b)* proximity to densely populated areas. In this way, consideration is given to areas which, although they themselves may be sparsely populated, are nonetheless relatively close to metropolitan areas and the medical facilities ordinarily available in such centers.

For practical purposes, service areas have been established so as not to cross county lines. Five groups of counties have been created. Metropolitan counties, which include the metropolitan districts of cities of 50,000 or more persons, have been subdivided into "greater metropolitan" and "lesser metropolitan," the former being in or around the twelve major cities of the United States. Counties geographically contiguous to any of the metropolitan counties are classified as "adjacent." The remaining counties have been subdivided into "isolated semirural" and "isolated rural," depending on the presence or absence of an incorporated place of 2,500 or more inhabitants.[1]

From the American Academy of Pediatrics Study of Child Health Services and the Division of Public Health Methods of the United States Public Health Service.

Read at the third annual meeting of the National Conference on Rural Health of the American Medical Association, Chicago, Feb. 6, 1948.

Because of lack of space this article has been abbreviated in The Journal by the omission of tables 4 and 5. The complete paper will be found in the authors' reprints, which the authors will be pleased to send on request to the American Academy of Pediatrics Study of Child Health Services, 2346 Massachusetts Ave., N.W., Washington 8, D. C.

[1] A county is classified as metropolitan if it has at least one city of 50,000 or more inhabitants. Counties are also classified as metropolitan if they include *(a)* densely populated areas touching metropolitan counties (adjacent and contiguous minor civil divisions which have a population of 150 or more per square mile), and *(b)* 50 per cent or more of the population of the county or at least 50,000 people within such densely populated areas. A greater metropolitan county is one in which there is located any part of metropolitan districts of 1,000,000 or more inhabitants in and around the cities of Baltimore, Boston, Chicago, Cleveland, Detroit, Los Angeles, New York, Philadelphia, Pittsburgh, St. Louis, San Francisco and Washington. Lesser metropolitan counties are all other metropolitan counties. Counties that touch a metropolitan county but are not themselves metropolitan have been classified together as adjacent counties, unless the nearest point of the county is more than 50 road miles (80.5 kilometers) from a city of 50,000 or more population. (A few nearby counties were classified as adjacent, on the basis of travel habits of the people, although these counties did not actually touch a metropolitan county.) Counties that do not touch any part of a metropolitan county have been subdivided into isolated semirural and isolated rural counties. An isolated semirural county has at least one incorporated place of 2,500 or more inhabitants, and an isolated rural county has no incorporated community of 2,500 or more inhabitants.

Figure 1 illustrates the county groups in and around the city of Chicago. The classification of each county in the United States is given in table 6.

The unusual feature of this manner of classification is in the use of the adjacent category.[2] It is recognized that a large hospital in an urban center serves not only the county in which it is located but also the surrounding counties. It is for hospital services and the services of specialists that the use of the term "adjacent" is particularly suitable. By grouping metropolitan and adjacent counties together, we have established a reasonably reliable service area for hospitals and specialist service so that comparisons may be made with the combined isolated counties. On the other hand, it is fair to assume that physicians and dentists in general practice tend to limit their practice to the communities in which they live or the immediately surrounding territory. Therefore, data for these physicians and dentists are discussed separately for each of the five county groups.

According to this classification, two thirds of the 3,076 counties in the United States are isolated; that is, predominantly rural and also far removed from metropolitan centers. Relatively few counties, 240, are metropolitan (table 1). The metropolitan and adjacent counties combined represent the areas which we have assumed are served by or are readily accessible to large urban medical centers.

Table 1.—*Counties in the United States by County Group and Size of Largest Urban Place*, 1940

		Counties with an Incorporated Place of		
	Total counties	50,000 or More Persons	2,500 to 50,000	Less than 2,500
Greater metropolitan ...	63	34	29	0
Lesser metropolitan	177	130	47	0
Adjacent	668	——	472	196
Isolated semirural	1,116	——	1,116	——
Isolated rural	1,052	——	——	1,052
Total	3,076	161	1,664	1,248*

Many of the adjacent counties (almost one third) are in themselves entirely rural by definition of the United States Census; that is, they have no incorporated place of 2,500 persons or more. However, since their inhabitants have the advantages of living near medical centers, they are much more favorably located than persons who live in the counties which are isolated as well as rural.

Table 2.—*Rural Population and Density of Population in the United States, by County Group*, 1940[*]

	Percentage of Total Population That Is Rural	Persons per Square Mile
Greater metropolitan	11	1,136
Lesser metropolitan	24	193
Adjacent	68	42
Isolated semirural	64	26
Isolated rural	100	10
Total	41	41

[*] From: Sixteenth Census of the United States: United States Department of Commerce, Bureau of the Census, 1. Population, United States summary, table 17, 1940.

Table 2 shows for each county group the proportion of the total population that is rural. In our classification, the only county group which is 100 per cent rural by definition is our isolated rural. About two thirds of the population of the isolated semirural and of the adjacent counties are rural, while even the population of the group of greater metropolitan counties is 11 per cent rural. Expressed in terms of density of population, the contrast is even more striking among the five county groups.

Analysis for individual states shows that there is a high degree of correlation between our county classification and counties grouped according to the size of their largest urban place.[3]

In any study of the availability of medical care, consideration must be given to the economic status of the community and to the individual's ability to pay. We have found a close correlation between our classification of counties and average per capita income. Figure 2 shows the average per capita income for the five county groups based on effective buying income.[4]

The average per capita income in isolated rural counties is about one third of that in metropolitan counties. The income level rises sharply between isolated rural and isolated semirural counties, and between adjacent and metropolitan counties. Adjacent and isolated semirural county groups have about the same average income per capita.

In general, the same pattern of association between per capita income and the county group classification holds within individual states.

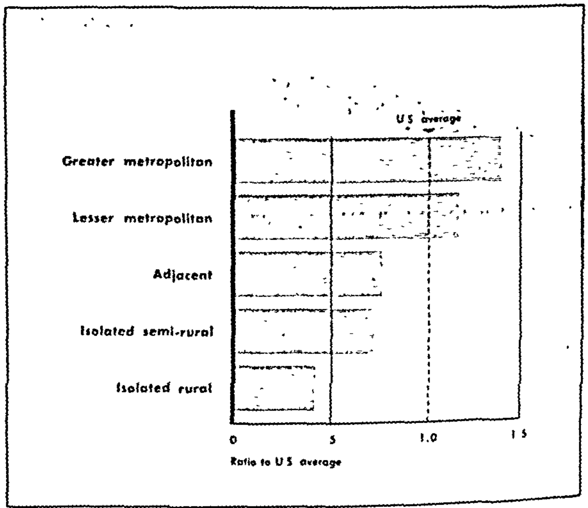

Fig. 2.—Average per capita income in the United States, by county group, 1940.

CHILD POPULATION, 1945

Since this study has been developed in order to determine health services currently available for children, it became necessary to have recent population data, at least for children. With the large shift in population during the war years, it was considered essential to determine the number of children county by county for 1945—figures which were not available elsewhere for this inter-census year.

---

[2] The basis of this classification was furnished by Elliott H. Pennell and the staff of the United States Public Health Service.

[3] For example, when the 100 counties in North Carolina are divided into 16 cells (4 by size of largest urban place times 4 by our county classification), the value of the coefficient of mean square contingency, c, is 0.76. The maximum value of c for a 4 by 4 table is 0.87.

[4] This is based on estimates of effective buying income in 1940, made by Sales Management and published in Sales Management 48: no. 8 (April 10) 1941. The estimates were made on the basis of money actually paid for goods and services, federal allotments, money paid out of savings and surpluses by business and financial institutions, plus the nonmoney income of farm and village residents. The income is gross income before taxes are paid. The estimate is based upon a formula devised by Sales Management. Per capita figures were computed on the basis of population as reported in the United States Census of 1940.

[5] North Carolina may again be used as an example. When the 100 counties are divided into 4 income classes and 4 county groups, the value of c, coefficient of mean square contingency, is 0.71 in this 4 by 4 table.

A method was devised for estimating population under 15 years of age as of July 1, 1945 for each county in the United States.[6]

According to these estimates, there were 36,000,000 children under 15 years of age in the United States as of July 1, 1945. Table 3 shows that 13,000,000 children—37 per cent of the total—are in isolated counties.

TABLE 3.—*Children in the United States, by County Group,* 1945

	Children under 15		
	Number	Percentage	
Greater metropolitan	8,371,690	23)	
Lesser metropolitan	8,635,100	24)	63
Adjacent	5,847,352	16)	
Isolated semirural	9,659,071	27)	
Isolated rural	3,199,573	10)	37
Total	36,005,795	100	100

It is this group of 13,000,000 children living in isolated counties with which we are particularly concerned in this discussion, for these are the children who are far removed from the health services and facilities of large urban centers. Children in these isolated counties do not have the same opportunities for medical care as do those children who happen to be living in more favored localities. Deficiencies appear in all aspects of health services and facilities: hospitals, physicians and dentists and community health services.

HOSPITALS, PHYSICIANS AND DENTISTS

Hospitals.—In surveying hospital facilities it has been impossible to obtain any count of the total number of beds used by children. Except in pediatric hospitals and those with separate pediatric units set aside exclusively for children, many beds are used interchangeably for children and adults according to need and circumstance. Therefore, for present purposes, we have based our calculations on the total number of beds[7] in all general hospitals which admit children, defining children as of the ages between birth and 15 years.

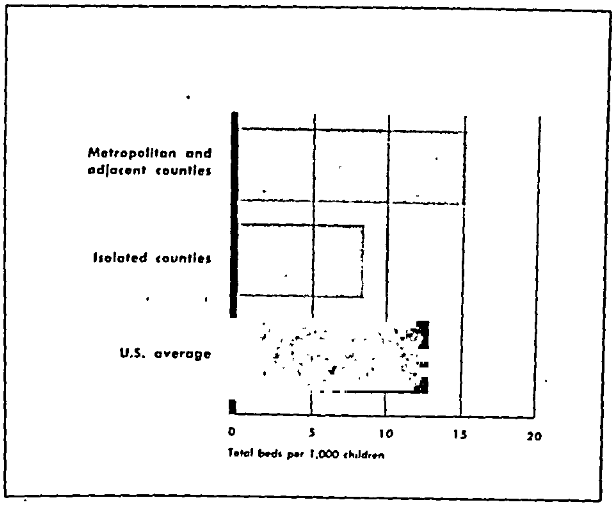

Fig. 3. Beds in general hospitals in the United States, by county group, 1946.

In 1946, there were approximately 463,000 such beds in the United States, a ratio of 3.3 to 1,000 persons.[8] When related to child population, the ratio becomes 12.8 beds to every 1,000 children.

As shown in figure 3, the ratio in the service areas made up of metropolitan and adjacent counties is 15.4; in isolated counties, 8.4. Thus children in isolated areas have only about half the relative number of hospital beds available locally for their care as have the children in or near large urban centers.

Physicians.—Of all physicians in the United States in 1946, 116,000 were recorded as in private practice.[9] This number excludes retired physicians and those in full-time academic, administrative, research or institutional positions, and those employed by federal, state and local health agencies. For the country as a whole, the number of physicians in private practice in relation to population is 0.8 per 1,000 persons (1 practicing physician per 1,200 persons).[8] Relating the total number of practicing physicians to child population, the rate becomes 3.2 per 1,000 children.

---

[6] Population under 5 years of age, as of July 1, 1945, was estimated for each county on the basis of the number of births for each of the five calendar years 1940 through 1944. Survival rates for each year of age were applied to the number of births occurring in each of the years. The rates used were those for each of the three major geographic regions of the United States and for white and nonwhite population separately in the South. The figures obtained by the application of survival rates to the births occurring in each of the five years 1940 through 1944 were added for each county, and these totals were corrected for under registration of births. The county estimates of total living population under 5 years of age were then adjusted to tally with the estimated population of the entire United States under 5 years of age as of July 1, 1945. The number of children aged 5 to 14 years, as of July 1, 1945, was estimated for each county on the basis of changes in school enrollment since 1940. The ratio of elementary public day school enrollment as of June 1945 to that of June 1940 was used to project to 1945 the 1940 census population in this age group for each county. The county estimates of population were then adjusted to tally with the estimated population of the United States for the ages 5 to 15 years as of July 1, 1945. Child population under 15 years of age was obtained by combining these two estimates. Sources were as follows:

[7] Beds in general, maternity and pediatric hospitals, both those registered by the American Medical Association and those unregistered, provided that they: *(a)* report five or more beds and *(b)* admit at least 10 children or 10 obstetric cases annually. Beds in general hospitals operated by the Bureau of Indian Affairs are included on the assumption that they represent facilities operated on a local area basis, but other federal hospitals are excluded. Also in the excluded group are maternity nursing homes, hospitals in jails, prisons and reformatories, school hospitals and infirmaries and health camps.

[8] Based on total population as of July 1, 1946. Child population by counties as of July 1, 1945, is used as the basis for rates by county group.

[9] A list of physicians in private practice was prepared in each state on the basis of all available sources of information, including the American Medical Directory: II. Physicians, Chicago, American Medical Association, 1942; membership lists of the state and county medical societies; records of the Procurement and Assignment Service, of the State License Bureau, of the State Health Department and of the Internal Revenue District offices. Schedules, sent to each physician listed, asked, "Are you engaged in private practice? If NO, state reason." For those physicians failing to return schedules, information as to whether or not each was engaged in private practice was obtained through local health officers, state and county medical societies or by telephone or postcard. This inquiry also served to determine whether or not these physicians considered themselves as specialists. Thus a final corrected list of all physicians in private practice was obtained. It should be noted that there was no exclusion of physicians who do not treat children. The lists were prepared between April and December 1946, except in the following states: North Carolina (November 1945), Mississippi (January 1947), Oklahoma (March 1947) and Wyoming (July 1947).

When we analyze the physician-child ratio according to county groups, pronounced inequalities are revealed. In figure 4 it is seen that the physician-child rate in isolated counties is one half of that in metropolitan and adjacent counties (1.8 as compared with 4.0 per thousand children).

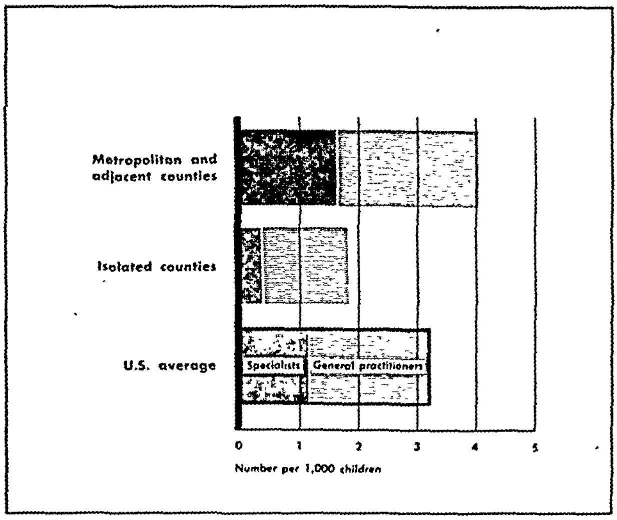

Fig. 4.—Physicians in private practice in the United States, by county group, 1946.

In analyzing the distribution of physicians, we should consider specialists and general practitioners separately. All physicians who reported that they limited their practice to a recognized specialty are defined as specialists. They tend naturally to concentrate in or near medical centers. The service areas around urban centers include 89 per cent of all specialists. The 13,000,000 children in isolated counties have relatively little specialist care available locally—0.3 specialists per thousand children as compared with over five times that rate (1.6) in the metropolitan and adjacent counties.

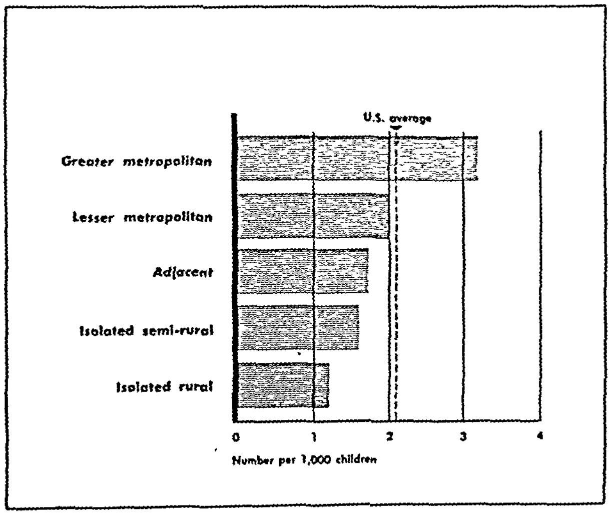

Fig. 5.—General practitioners in private practice in the United States, by county group, 1946.

All children should have equal opportunities to benefit from the highly skilled knowledge and technic of specialists. However, in a large proportion of cases, specialist care does not constitute an emergency. The child may be taken to the specialist or the specialist brought to the child, even though he lives far away in an isolated rural county.

In the case of the general practitioner, however, the situation is different. Just as many *general* practitioners are needed to care for 1,000 children in isolated rural areas as in the metropolitan areas. In fact it may be argued that more general practitioners are required in proportion to population in isolated areas, since the specialists are fewer and also distances are greater. The ratio of general practitioners is shown therefore for each of the five county groups in figure 5. There are 3.2 general practitioners for every 1,000 children in the greater metropolitan counties, but only 1.2 in isolated rural counties.

Dentists.—The scope of our study has included dental care for children. Dental caries shares with the common cold the unenviable honor of the commonest disease of children as well as adults. Any survey of child health services must therefore give serious attention to the distribution of dentists and the care they render to children.

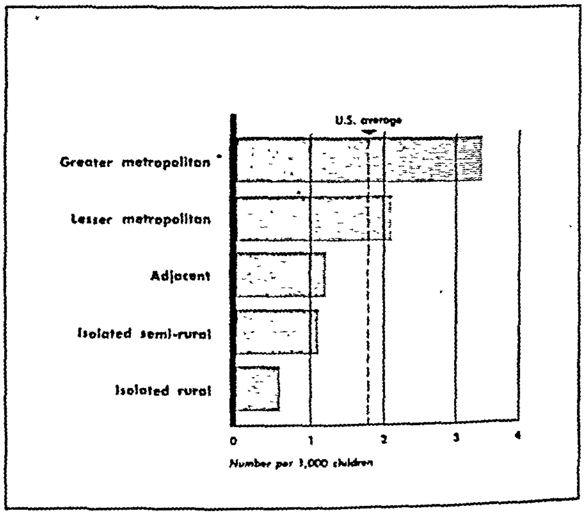

Fig. 6.—Dentists in private practice in the United States, by county group, 1946.

In 1946 about 66,000 dentists were reported in private practice in the United States.[10] Since our data do not show how many of these dentists accept children as patients, we have used the total number in relation to child population and, for the purposes of this discussion, have not separated specialists from those in the general practice of dentistry. As in the case of physicians in general practice, inadequacy of care and neglect of health results if dentists are not readily available. The rural child who must travel far to see a dentist gets inadequate dental care or none at all.

Figure 6 shows that there are 1.8 dentists per thousand children in the United States. In the isolated rural counties the rate is 0.6, or less than one fifth that in the greater metropolitan counties (3.4). Thus the distribution of dentists follows the same pattern as that of physicians, with a concentration in or near large urban centers. As in the case of the medical general practitioners, the rates in adjacent and in isolated-semirural counties are nearly identical and much lower than in lesser metropolitan counties.

---

[10] A list of dentists in private practice was prepared in each state using similar methods to those described for physicians in footnote 9. The lists were prepared between April and December 1946, except in the following states: North Carolina (January 1946), Indiana (January 1947), Mississippi (January 1947), Oklahoma (March 1947) and Wyoming (July 1947).

DEFICIENCY IN HOSPITAL BEDS, PHYSICIANS AND DENTISTS IN ISOLATED COUNTIES

A graphic summary of the deficiency in hospital beds, physicians and dentists in relation to the population in the isolated counties is shown in figure 7. About one third of the total population

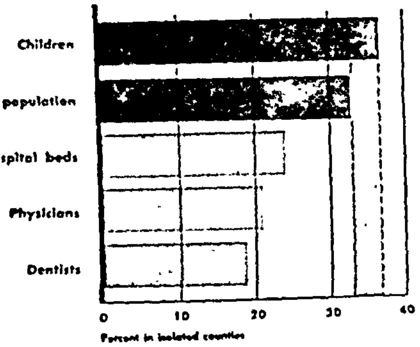

Fig. 7.—Summary for isolated counties in the United States.

live in these isolated counties.[11] Locally available to this third of the population are 24 per cent of the hospital beds, 21 per cent of the physicians and 19 per cent of the dentists. As shown in figure 7, the gap between the lengths of the columns for hospital beds, physicians and dentists and that for total population is an indication of the deficiency in these three categories of health services.

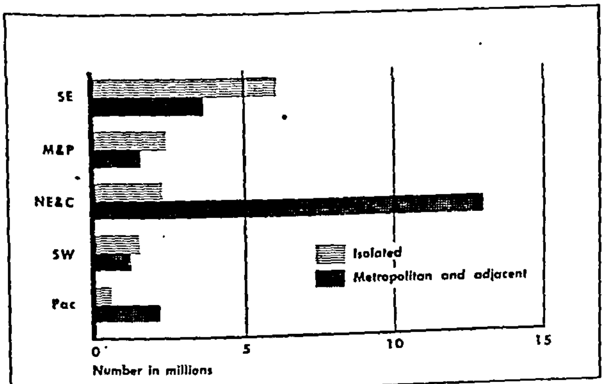

Fig. 8.—Summary for regions in the United States, by county group, 1946: children.

In respect to children, the deficiency is even greater. Rural families are on the average larger than those in cities, so that in these isolated counties the proportion of children is relatively greater. The 13,000,000 children in the isolated counties, who constitute 37 per cent of the children of the United States, get distinctly less than their share of the service of hospitals, physicians and dentists located in their own areas.

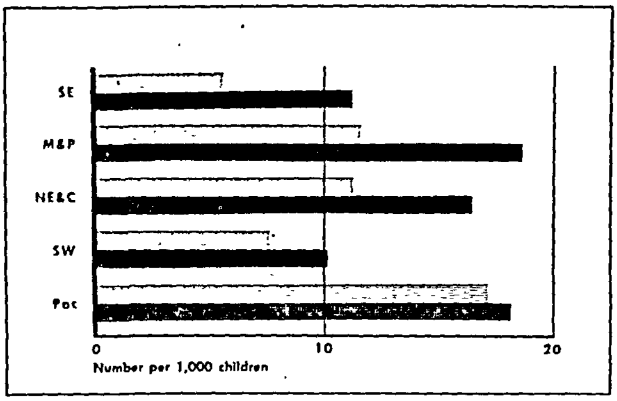

Fig. 9.—Summary for regions in the United States, by county group, 1946: beds in general hospitals.

It is recognized that sparsely settled communities actually require within their boundaries fewer hospital beds for every thousand persons than are needed in cities. In cities, with their medical centers, specialists and highly skilled professional services, hospitals not only serve the patients among their own urban populations, but also admit for diagnosis and treatment many of the patients with more difficult cases referred from nonurban areas. This difference in the number of beds required in urban areas as compared with rural areas has been taken into account in the standards recommended by the United States Public Health Service. On the basis of their proposed allotments among hospital districts, it is estimated that the number of general beds in isolated counties would have to be increased by at least 50 per cent.[12]

In respect to physicians and dentists, serious deficiencies exist in isolated areas. It has already been stated that isolated counties need as many, if not more, general practitioners for every 1,000 persons as are needed in the greater metropolitan counties if children in these counties are to have equal opportunity for medical care and health supervision. In order to assure that children in isolated counties have available to them in their own areas general practitioners at a rate available to

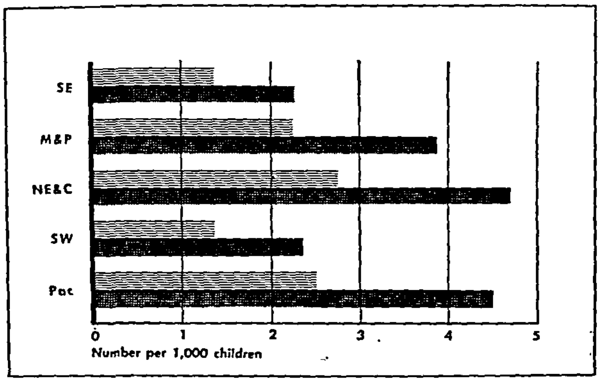

Fig. 10.—Summary for regions in the United States, by county group, 1946: physicians.

---

[11] Although, as indicated previously, estimates of child population for each county as of July 1, 1945 were made in connection with this study, no corresponding estimates were practicable for the population of all ages. Tabulation of data from the 1940 Census, however, show that 33 per cent of the total population and 38 per cent of the children live in isolated counties:

	Children Under 15	Total Population
Greater metropolitan	7,565,504	36,402,167
Lesser metropolitan	7,281,471	31,813,041
Adjacent	5,442,993	20,284,884
Isolated semirural	9,125,551	31,999,012
Isolated rural	3,556,562	11,170,141
Total	32,972,081	131,669,275

[12] Based on a special tabulation of the data, in Mountin, J. W.; Pennell, E. H., and Hoge, V. M.: Health Services Areas—Requirements for General Hospitals and Health Centers, Public Health Bulletin no. 292, Federal Security Agency, United States Public Health Service 1945.

the children in the greater metropolitan counties of the United States, the present count of 19,600 general practitioners in these counties would have to be doubled. On the same basis, the present number of 12,700 dentists in isolated counties would have to be tripled.

Regional Differences.—So far comparisons have been made between county groups for the country as a whole. If now the country is divided on a regional basis, glaring deficiencies in health services are revealed in some sections of the country in comparison with others.

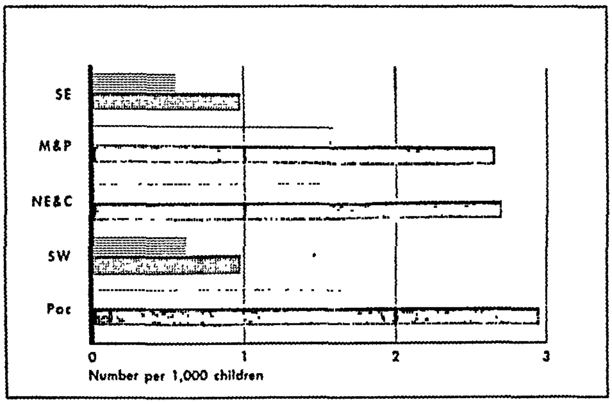

Fig. 11.—Summary for regions in the United States, by county group, 1946: dentists.

For the purpose of this study the states have been grouped into five regions. Without attempting to give a full description of regional differences at this time, we may call attention to certain deficiencies in the Southeast region. This is an area which is predominantly rural, with a large proportion of the country's rural children. In our group of isolated counties in the Southeast region, there are 6,000,000 children—almost half of the total 13,000,000 children of the United States living in isolated counties (fig. 8).

These isolated counties in the Southeast region show the lowest rates of general hospital beds, physicians and dentists of any of the five regions presented in figures 9, 10 and 11. Hospital facilities are available at a rate only half of that for metropolitan and adjacent counties in the same region. Children in isolated counties in the Pacific region, the region with the highest rate, have three times as many hospital beds per child. Discrepancies of about the same magnitude are apparent for physicians and for dentists.

When a comparison of facilities and personnel is made state by state, the lowest rates are usually found in the twelve states of the Southeast region (table 6).

Community Health Services.—It is sometimes assumed that, although children in rural areas have less than their share of the services of physicians in private practice, this is at least in part compensated by an increase in community health services such as well-baby clinics, public health nurses and dental clinics. Such, however, is not the case. In fact the reverse is true. We have already reported[13] that the amount, distribution and character of community health activities are also weighted heavily in favor of children in urban areas.

CONCLUSION

These facts, only a few of the many which are being sharply defined by the Academy's study, reveal in specific detail inequalities in the amount of medical care received by children in rural areas. Children living in these areas are handicapped particularly in specialist care, clinic care and the highly skilled diagnostic and treatment services received in hospitals—those very services which have been agreed on as the right of every child.

Now that the facts have been obtained, the American Academy of Pediatrics, with the continuing cooperation of the United States Public Health Service and the United States Children's Bureau, has undertaken an action program for the improvement of child health not only for the country as a whole but for every state, county and local community. The field is limitless in its scope, but already certain specific projects have been planned. Most prominent among the projects for first consideration are: (1) to strengthen pediatric teaching in order

to provide more physicians who are well trained in the medical care and health needs of children, especially in remote areas, and (2) to develop and implement recommendations made by state and local communities in order to provide better and more evenly distributed health services for all children, particularly in rural areas where adequate services are now deficient.

AORTIC PULMONARY ANASTOMOSIS IN CONGENITAL PULMONARY STENOSIS

Report of Forty-Five Cases

WILLIS J. POTTS, M.D.
and
STANLEY GIBSON, M.D.
Chicago

In November 1946, Potts, Smith and Gibson[1] reported a new surgical procedure for the relief of congenital pulmonary stenosis. The operation consists of a direct anastomosis between the aorta and a pulmonary artery. The use of the aorta was made possible by the invention of a clamp which permits blood to flow through this vessel while the anastomosis is being performed. This technic differs from the Blalock and Taussig[2] method only in the fact that the aorta itself rather than one of its branches is used to direct additional blood to the lungs.

Anastomosis between the aorta and a pulmonary artery has been performed on 45 patients, and in addition 7 patients have been explored in whom the anastomosis was not undertaken. We shall first discuss the criteria used in the selection of these patients for operation.[3]

DIAGNOSIS

In 48 of the 52 patients submitted to operation, the preoperative diagnosis was the tetralogy of Fallot. This syndrome is by far the most frequent condition in which the circulation to the lungs is inadequate. It consists of pulmonary stenosis, defect of the interventricular septum, aorta overriding the septal defect and hypertrophy of the right ventricle.

The characteristic clinical picture is that of a patient who is cyanotic, especially about the eyes, nose, mouth and tips of the fingers and toes. The eyes are suffused. The fingers and toes are clubbed. The patient is usually unhappy and irritable, and the state of nutrition is often poor. In some instances there is retardation in mental development. Physical examination reveals the heart to be normal in size or only slightly enlarged, with a systolic murmur best heard along the left sternal margin at about the second or third left interspace. Roentgenologic examination shows a heart that is boot shaped, the apex being blunt and rounded and the heart appearing to lie more or less transversely in the chest. The pulmonary fields show little vascularity. Fluoroscopic examination fails to reveal pulsations in the hilar regions, and in the left anterior oblique position the pulmonary window is abnormally clear. The electrocardiogram is characterized by pronounced axis deviation to the right. The red cell count and hemoglobin are elevated. The arterial oxygen saturation is diminished.

Such is the classic picture of the tetralogy of Fallot, and under such circumstances the diagnosis can be made with confidence. There are, however, many variations from this typical pattern, and on this account we shall discuss briefly a number of the diagnostic points which have been mentioned.

The degree of cyanosis varies widely. In some of the children, cyanosis was scarcely noticeable when the patient was at rest. There was likewise a wide variation in the red cell count and hemoglobin. In our series the red cell count varied between 5,000,000 and 10,000,000. Nor was there as close correlation between the red cell count and hemoglobin as one might expect. Moreover, the degree of cyanosis, the number of red blood cells or the amount of hemoglobin did not necessarily show a close relationship to the patient's limitation of activity. Some who were decidedly cyanotic with high red cell counts and hemoglobin were able to walk several blocks before becoming breathless. Others, who from their general appearance and blood examination would appear to be less severely handicapped, were able to walk only a few yards. The inability to exercise would seem to be the most important criterion in deciding whether operation is urgently indicated.

Examination of the heart usually reveals a systolic murmur which is best heard along the left sternal margin at about the second and third interspaces. Sometimes it is long, harsh and rasping, while in other instances it is short and of slight intensity. A thrill may or may not be palpable. Absence of a murmur is a cause for anxiety. Operation has been performed on 2 children in whom no murmur could be detected. In 1 a satisfactory anastomosis was completed, and the patient made an uneventful recovery. In the other, the pulmonary artery was too small to allow the anastomosis to be effected, and the patient failed to survive the exploration.

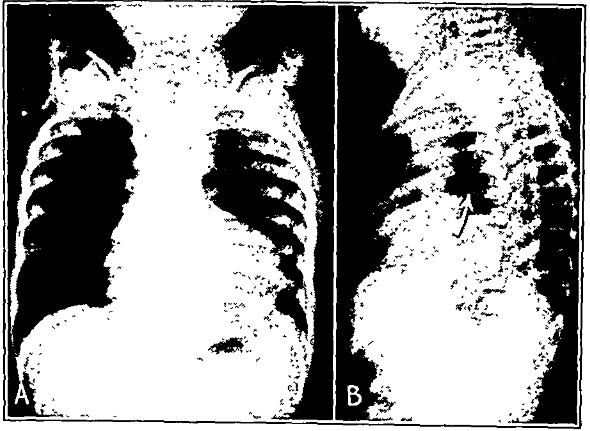

Fig. 1.—*A*, typical boot-shaped heart. *B*, left anterior oblique view, showing clear pulmonary window (indicated by arrow).

Autopsy revealed the characteristic features of the tetralogy save that pulmonary atresia rather than stenosis was present. A large interventricular septal defect was present, but in this instance at least, its presence had not resulted in an audible murmur. It is our belief that the first of these 2 patients also had pulmonary atresia, but was fortunate in that the pulmonary branches were sufficiently large to allow the anastomosis. Failure to hear a murmur should put one on his guard both as to diagnosis and prognosis, in the event that operation is decided on.

Roentgenologic study is perhaps the most important single feature of the examination. A 2 M. roentgenogram of the chest in the anteroposterior position almost

[2] Blalock, A., and Taussig, H. B.: The Surgical Treatment of Malformations of the Heart in Which There Is Pulmonary Stenosis or Pulmonary Atresia, J. A. M. A. **128:** 189-202 (May 19) 1945.

[3] In this connection we wish to state that Dr. Helen Taussig and her co-workers at the Johns Hopkins Clinic have taught us much in our frequent visits there.

always reveals a heart that is normal in size or only slightly enlarged. Gross cardiac enlargement militates strongly against the diagnosis of the tetralogy of Fallot. In no case in our series has the heart been estimated as more than 25 per cent enlarged.

The shape of the heart is subject to considerable variation. It is gratifying if the roentgenogram shows a heart that is boot shaped, appearing to ride high on the diaphragm, lying more or less transversely in the chest (fig. 1 *A*). However, the heel of the boot is often inconspicuous, and the heart may be found in its normal position with little blunting of the apex. In several instances our roentgenologist has pronounced the heart to be of normal size and shape. A slight concavity is usually present in the pulmonary area, or the contour may appear normal. Prominence in the region of the pulmonary conus indicates a large pulmonary artery and should immediately cast doubt on the diagnosis of the tetralogy of Fallot. The appearance of the hilar regions must also be noted. If there is evidence of increased vascularity, it is an important sign that the lungs are receiving a sufficient amount of blood.

Fluoroscopic examination is important in determining the amount of blood flow through the pulmonary arteries. With the eyes thoroughly accommodated search should be made for expansile pulsations in the hilar regions. Absence of pulsations is the rule in pulmonary stenosis. Their presence means that the flow of blood to the lungs is adequate. Fluoroscopic study of the patient in the left anterior oblique position is obligatory. In this position one is able to determine whether there is an abnormally clear area beneath the aortic arch; in other words, whether the pulmonary arteries are carrying less than the normal amount of blood. An abnormally clear pulmonary window is one of the most reliable signs of pulmonary stenosis (fig. 1 *B*).

The electrocardiogram usually shows an extreme degree of axis deviation to the right. In most instances QRS_1 is practically altogether downward with QRS_3 upright. P waves, particularly in lead 2, are high and pointed (fig. 2 *A*) Once the diagnosis of the tetralogy of Fallot has been made, it is still necessary to determine the position of the aortic arch before operation is undertaken. In 15 to 20 per cent of cases, the aorta descends on the right. In order to do the anastomosis one must enter the chest on the side on which the aorta lies. In our series a right aortic arch was encountered in 7 instances.

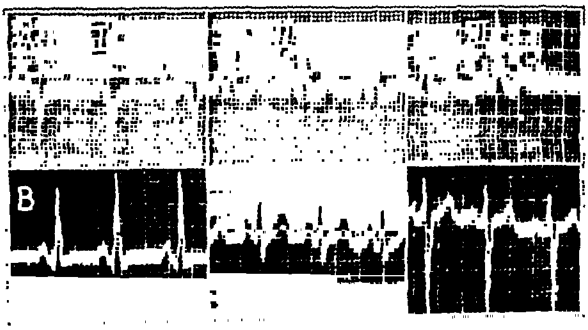

Fig. 2.—*A*, axis deviation to the right in tetralogy of Fallot. *B*, axis deviation to the left in tricuspid atresia.

The position of the arch can often be determined by simple inspection of the anteroposterior roentgenogram of the chest, particularly when it lies on the left. The aortic knob and the descending aorta may be well outlined. In other cases, one must use a barium swallow, and observe under the fluoroscope the deflection of the barium to the right or left. Indentation of the esophagus on the left indicates a left arch, and vice versa. In a number of young, uncooperative patients, we have found it helpful to administer a thick barium mixture with the patient lying supine and the foot of the fluoroscopic table elevated. A roentgenogram is made just after the patient has swallowed (fig. 3). In this way, the entire course of the esophagus can frequently be well outlined. (Some confusion has arisen from the use of the terms "dextroposition of the aorta" and "right aortic arch." Dextroposition of the aorta refers to the position of the aorta at its origin, and means that the aortic orifice is shifted to the right, overriding the accompanying interventricular septal defect and thus arising from both ventricles rather than the left ventricle alone. Dextroposition of the aorta is an integral part of the tetralogy of Fallot and carries no implication as to the position of the aortic arch, which may be either on the right or left.)

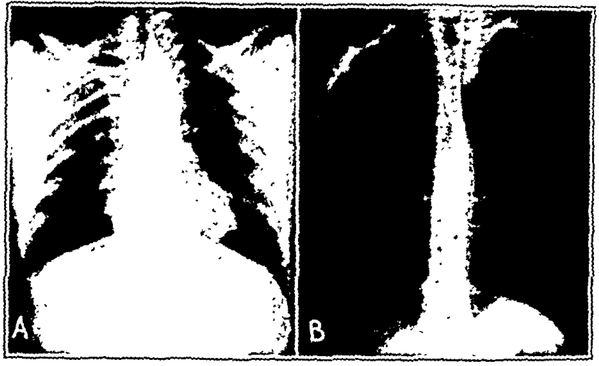

Fig. 3.—*A*, barium-filled esophagus with indentation on left indicating left aortic arch. *B*, indentation on right indicating right aortic arch.

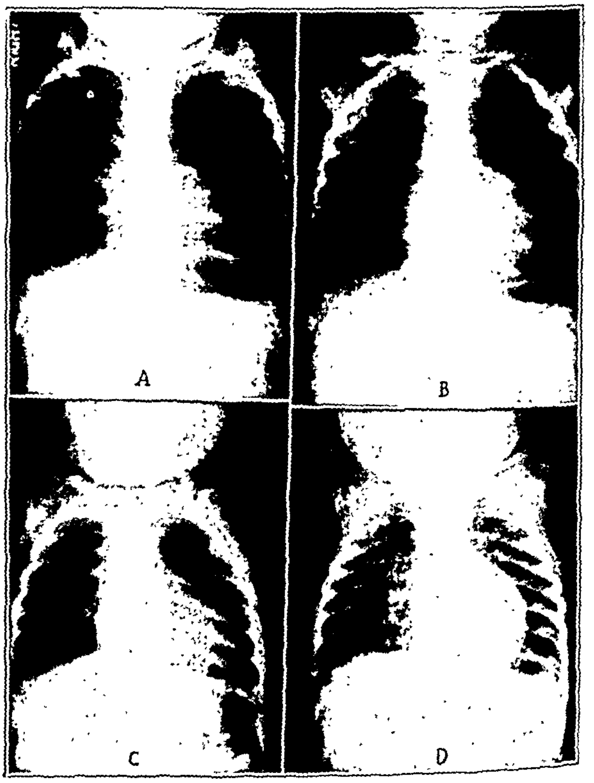

Fig. 4.—Anteroposterior roentgenograms of the 4 patients in whom a diagnosis of tricuspid atresia was made.

In 4 of the patients who came to operation, the clinical diagnosis was tricuspid atresia. A number of other characteristic defects usually accompany this lesion: namely, interauricular septal defect, defect of the interventricular septum, rudimentary right ventricle and hypoplasia of the pulmonary artery. The course of the flow of blood from the right auricle is as follows: through the interauricular septal defect into the left auricle, thence to the left ventricle, where a portion of the mixed blood from the left ventricle passes through an interventricular septal defect into the diminutive right ventricle and on into a more or less narrowed pulmonary artery.

The physical signs are identical with those encountered in the tetralogy of Fallot. There are the same cyanosis and clubbing, the same findings with respect to the blood and the same systolic murmur over the precordium. There are, however, two important features which serve to distinguish tricuspid atresia from the tetralogy. The roentgen silhouette in the anteroposterior view shows a gentle rounding of the left cardiac border due to hypertrophy of the left ventricle and an absence of the normal fulness of the region of the right ventricle (fig. 4). The second diagnostic feature is axis deviation to the left in the electrocardiogram (fig. 2 *B*). These features were present in all 4 of our patients. Three of the patients had a pulmonary artery sufficiently large to permit a satisfactory anastomosis, and all 3 made a satisfactory recovery with striking improvement. In the fourth case, the pulmonary artery was rudimentary, and no anastomosis could be done. The patient survived the exploratory operation.

In some cases of tricuspid atresia, there is no communication between the two ventricles and blood must reach the lungs by way of a patent ductus arteriosus. Such was not the case in any of our 4 patients. Inasmuch as the anastomosis is done in the immediate vicinity of the ductus, the question of its patency can be determined by inspection during the operation.

OPERATION

From Sept. 13, 1946 to Aug. 15, 1947, aortic pulmonary anastomosis for relief of cyanosis due to congenital pulmonary stenosis has been performed on 45 patients.* In addition, 7 patients were explored.

Although the technic of operation remains substantially the same as originally outlined, emphasis on important steps, clarification of misunderstood points and a description of slight modifications in technic will be reviewed.

In addition to careful selection of patients suitable for operation, skilful anesthesia is essential for operative success. The rather severe grades of anoxemia allow these patients a narrow margin of safety over which an expert anesthetist must carry them. Without the services of a well trained anesthetist, capable of giving intratracheal anesthesia, resourceful in emergencies and conscious of the significance of the slightest change in pulse, respiration and blood pressure, the mortality will rise appreciably. In no operation is the work of the anesthetist more important.

The child is placed in a lateral position on the operating table and the chest is entered through a posterolateral incision in the left fourth interspace if the arch of the aorta curves normally to the left (fig. 5 *A*). In case of a right aortic arch the incision is made in a similar manner on the right side.

Identification of the right or left pulmonary artery is usually not difficult. In some cases it is small and buried in masses of small tortuous thin-walled veins and fibrous tissue. Since the loss of blood is less hazardous to these plethoric children the veins are dissected from the pulmonary artery with a fair degree of confidence. The large veins are tied with fine silk; bleeding from the tiny veins is disregarded.

We use no sponges in the chest. The blood is lavaged away from the operative site with a stream of isotonic solution of sodium chloride removed with an aspirator. The chloride solution, delivered with an ordinary 50 cc. bulb syringe, not only is nontraumatic, but also is effective in removing the dark blood caught in the meshes of adventitia, thus making important structures identifiable.

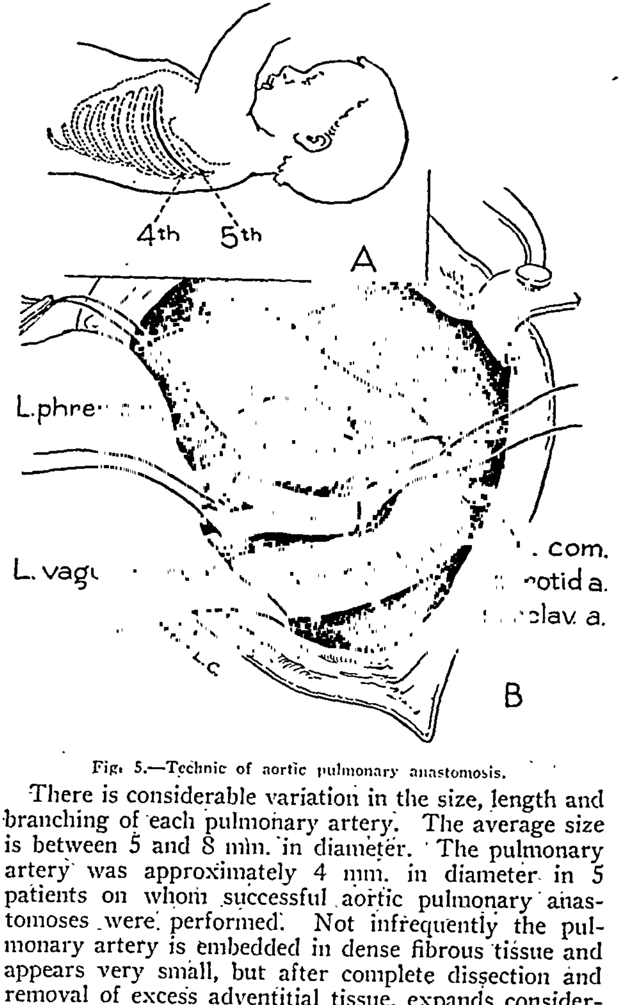

Fig. 5.—Technic of aortic pulmonary anastomosis.

There is considerable variation in the size, length and branching of each pulmonary artery. The average size is between 5 and 8 mm. in diameter. The pulmonary artery was approximately 4 mm. in diameter in 5 patients on whom successful aortic pulmonary anastomoses were performed. Not infrequently the pulmonary artery is embedded in dense fibrous tissue and appears very small, but after complete dissection and removal of excess adventitial tissue, expands considerably. In 1 patient the pulmonary artery was actually 18 mm. in diameter, measured with a caliper, twice the size of the adjacent aorta. The intrapulmonary pressure was practically zero and a successful anastomosis was performed with good results.

The left pulmonary artery is longer than the right and usually does not break up into branches before entering the hilus of the lung as does the right. The left pulmonary artery lies fairly near the aorta and courses in almost the same plane, whereas the right pulmonary artery lies near the inferior portion of the hilus of the lung and courses in a plane almost perpendicular to the aorta. It was feared that anastomosis of a pulmonary artery to an aorta lying at right angles to it would result in kinking and obstruction of the newly formed channel. This has not been true in 7 patients in this series who had right aortic arches and on whom successful anastomoses were performed. The pulmonary artery is very elastic and easily adjusts itself.

Worries about intrapulmonary pressure are for the most part needless. By observation of partial or complete absence of pulsations in the pulmonary artery and by palpation of the faintly beating vessel it is possible in most instances to decide promptly that the intrapulmonic pressure is below normal. If any question arises, the pressure can be determined easily by a simple water manometer consisting of a needle attached to rubber tubing to a calibrated pipet.

Doubly encircling ligatures of no. 00 oiled silk are placed around each branch of the pulmonary artery as it enters the hilus of the lung and around the pulmonary artery as far proximal as possible (fig. 6 *A*).

These ligatures are laid aside until ready for the actual anastomosis. The method of temporarily obliterating the pulmonary artery and fixing it with these ligatures to the aortic clamp during the anastomosis has been modified (fig. 6 *A*). One end of the ligature doubly encircling the distal branch of the pulmonary artery lying nearest the aortic clamp is threaded through the posterior flange of the distal portion of the clamp in one direction and through the anterior flange in the opposite direction. The other end of this same ligature is threaded through the flanges of the clamp in the opposite direction. The ends of the ligature are then drawn up snugly to appose the pulmonary artery to the aorta in the best possible position for anastomosis and tied just tightly enough to occlude but not injure the vessels. The ligature around the proximal portion of the pulmonary artery is attached to the flanges of the other end of the clamp in the same manner.

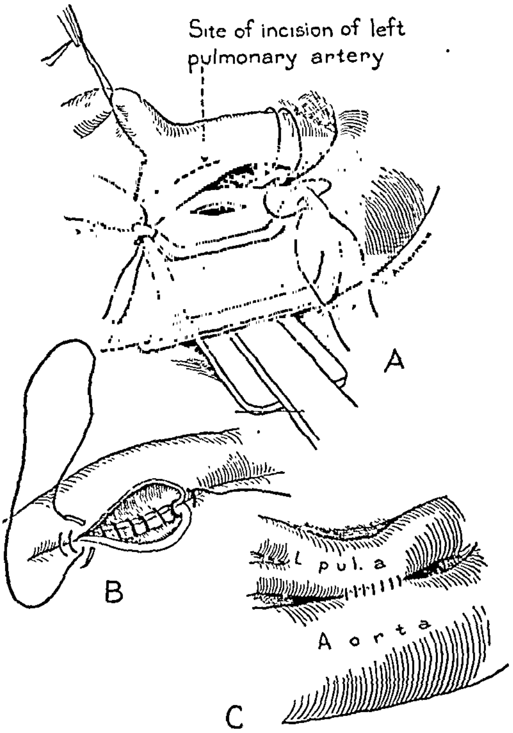

Fig. 6.—Technic of aortic pulmonary anastomosis.

There have been no changes in the aortic clamp. It is made in three sizes, small, medium and large. The medium-sized clamp is used for most patients. For children below 1 year of age, and for a few older children with rather small aortas, the small-sized clamp was used. The large clamp was used on 2 rather large children, both aged 12. It is imperative after the clamp is applied to the aorta and closed that a thrill be palpable in the aorta distal to the clamp in order that sufficient blood flow to the spinal cord is assured.

The site of anastomosis to the aorta is determined by the position of the pulmonary artery. This point is usually about 2 cm. distal to the origin of the subclavian artery.

The length of the incision in the aorta and pulmonary artery has been the subject of much discussion and concern. The desirable size of the final anastomotic channel will be dealt with later.

The technic of continuous, over and over suture with no. 5-0 Deknatel silk has not been changed (fig. 6 *B*)

On completion of the anastomosis and release of the ligatures and clamp, there has been in each case a continuous palpable thrill over the site of the new channel, indicating that blood was flowing through (fig. 6 *C*). In 3 patients one extra stitch was necessary to stop bleeding from the suture line.

On completion of the operation the lungs are carefully and fully expanded. In the sixth intercostal space a small stab wound is made in the chest and a de Pezzer catheter, so cut as to leave only a flange, is pulled through the chest wall from the inside out to provide drainage. The ribs are apposed with two heavy catgut sutures encircling adjoining ribs. The periosteum is dissected from the lower margin of the rib at the point where the catgut is to be introduced so as to avoid pressure on the intercostal nerve. The muscle layers are closed with running surgical gut sutures and the skin with silk.

The child is returned to its room and placed in an oxygen tent for a day or two. The chest drain is connected with a water seal and left in the chest three days. Penicillin, 30,000 units every three hours, begun two days before operation, is continued after operation for seven to ten days routinely.

Postoperative complications have been few. One or two aspirations of fluid and/or air from the chest were necessary in 4 patients. All occurred in the early cases before it became routine to place a drain in the chest at the close of operation. Severe tracheobronchitis with laryngeal edema necessitating tracheotomy occurred in 2 patients. Three patients had mild tracheobronchitis which was relieved by a day or two in the steam room. One of these children had an associated collapse of the upper lobe of the left lung which reexpanded without difficulty. Cerebral anoxia in 1 patient caused total paralysis for three days. Recovery was complete. The average period of hospitalization after operation was fifteen days.

MORTALITY

Aortic pulmonary anastomosis has been performed on 45 patients, of whom 4 died, a mortality of 8.8 per cent (the table). Of 10 children in the first group, 3 were below 1 year of age—4, 6 and 8 months respec-

Mortality Statistics

Ages	Number of Patients	Deaths	Mortality, Percentage
4 mo. to 2 yr.	10.	1	10
2 to 5 yr.	19	2	10.5
5 to 13 yr.	16	1	6.3
Total	45	4	8.8

tively. In the first 11 patients operated on there were 3 deaths; in the next 34 patients there was 1 death.

The first death, in a child aged 11 years, previously reported, was due to cerebral thrombosis. She had had hemiplegia since infancy. The second death, in a child aged 1.5 years, was likewise due to cerebral thrombosis. This child also had had a cerebral accident four months before operation. The third death, in a child aged 2.5 years, was due to postoperative shock and tension pneumothorax consequent to apical tuberculosis unrecognizable preoperatively. These 3 children died within twenty-four hours after operation. Hemorrhage into the hypothalamus was the cause of the fourth death, which occurred three days after operation.

Seven operations proved to be exploratory only. One child had an unrecognized Eisenmenger complex not remediable by surgery. The other 6 were hopeless from a surgical point of view because only strandlike pulmonary arteries carrying no blood were found at operation. Three of this group of 7 failed to survive the unavoidable increased anoxemia attendant on opening the chest. In fact, 2 died on the operating table and the third died in two days without regaining consciousness. Two of these children were in no worse condition preoperatively than many in the previous group on whom an anastomosis could be performed and who made uneventful postoperative recoveries. The third was a very poor surgical risk. Postmortem findings in all were essentially similar, confirming the operative diagnosis of undeveloped nonfunctioning pulmonary arteries due to pulmonary atresia. Bronchial arteries arising from the ascending and descending portions of the aorta were the only carriers of blood to the lungs.

Considering the patients who died after exploration only, in contrast with patients in similar preoperative condition who survived aortic pulmonary anastomosis, this observation presents itself: The child who has a pulmonary artery suitable for anastomosis has postoperatively an increased flow of blood to the lungs and can survive the shock of an open chest and temporary occlusion of a pulmonary artery, whereas the child who has an inadequate pulmonary artery and consequently cannot receive the benefit of anastomosis and increased blood flow to the lungs withstands the shock of an open chest poorly.

COMMENT

Of 41 patients who survived surgery, 39 have been tremendously improved; i. e., they are relieved of cyanosis, have gained weight and are able to live fairly normal lives. Two patients are improved; their cyanosis is only partially relieved and on exertion they still become somewhat cyanotic. It is only a year since the first child was operated on, so that no conclusions can be drawn as to ultimate prognosis. No child has died since discharge from the hospital. To date endocarditis has not developed postoperatively. That the anastomotic channels are remaining open and functioning is known from the persistence of a soft systolic and diastolic humming top murmur heard in all children examined and from the fact that cyanosis has not recurred.

Selection of patients for operation has been on the basis of diagnosis alone. No child has been refused surgical treatment regardless of a seemingly hopeless prognosis if the preoperative diagnosis indicated a decreased flow of blood to the lungs probably remediable by surgical treatment. Six of the patients operated on were in such a severe state of anoxia that they could barely sit up in bed, and 3 had to have intermittent or continuous oxygen. Anastomosis was possible in all these children, and oddly enough all survived.

It must be appreciated that children who have had an aortic pulmonary anastomosis for pulmonary stenosis have not been restored to normal. The basic pathologic condition remains in their hearts and extra work is added by the creation of an artificial ductus arteriosus. However, the children are comfortable and happy and their mothers have been relieved of constant anxiety.

The average preoperative red blood cell count was 7,930,000. Two weeks after operation it had fallen to 5,620,000. The hematocrit reading dropped from an average of 64.4 per cent preoperatively to 51 per cent two weeks after operation. The oxygen saturation level of arterial blood was raised an average of 30 per cent. The greatest change was in the tolerance of exercise. Before operation many children were unable to walk more than a few yards. After operation they could walk as far as their undeveloped legs would carry them. Some of the clubbing of the fingers and toes disappears during the first two weeks after operation, and the balance is gone by four to six months.

It has not been possible to follow all the children postoperatively, because many live far from Chicago. In those that have been followed there has been in every instance some enlargement of the heart. This enlargement has not been progressive but seems to become fixed within a month or two. In 3 children there has been pronounced enlargement of the heart. No signs of heart failure have developed but we are fearful that they may appear in the relatively near future.

How large should the anastomotic channel be made? Should it be smaller in a 1 year old than in a 12 year old child? Will the opening grow larger as the child grows? The final answer to these important questions awaits years of clinical experience and further experimental work. The objective sought is a ductus large enough to divert sufficient blood to the lungs to relieve cyanosis but not so large as to cause undue cardiac strain. Originally, we decided on 5/16 inch (8 mm.) as the proper length for the incisions in the aorta and pulmonary artery. Obviously the length of the incision is not the diameter of the final opening. By multiplying 5/16 inch (8 mm.) by 2 and dividing by 3.1416 we arrive at the final diameter of the newly formed ductus, or *slightly less than 1/5 inch* (5 mm.). All measurements are made with a caliper.

Recently we shortened the incisions to 1/4 inch (6.3 mm.), thus forming a final anastomotic channel of approximately 4 mm., or slightly less than 1/6 inch, *in diameter*. When one is dealing with structures which vary in elasticity and thickness it is improper to assume that mathematical accuracy is possible. Furthermore, accuracy of suturing, especially at the corners, is a large factor in determining the size of the newly formed ductus arteriosus.

SUMMARY

Essential points in the diagnosis of the tetralogy of Fallot and tricuspid atresia are discussed. Important features of the technic of aortic pulmonary anastomosis are reviewed. Aortic pulmonary anastomosis has been performed on 45 patients with 4 deaths, or a mortality of 8.8 per cent.

GUEST PASSENGER INJURIES

CLAIRE L. STRAITH, M. D.
CHIEF, PLASTIC SURGERY DIVISION
HARPER HOSPITAL
Detroit

Accidental injuries to occupants of the front seat of automobiles are so typical that they can be classified into two groups. The injuries sustained by the driver have become known as "steering post injuries" and those sustained by others in the front seat are classified as "guest passenger injuries."

Steering post injuries are caused by sudden stops when the driver is forced against the steering wheel. Frequently the chin is lacerated, the mandible may be fractured, and in more severe injuries the maxilla and nose may be involved. Chest, knee and ankle injuries are also common.

Drivers nevertheless occupy the safest seat in the car; protected by the steering wheel, they escape injury in many severe accidents.

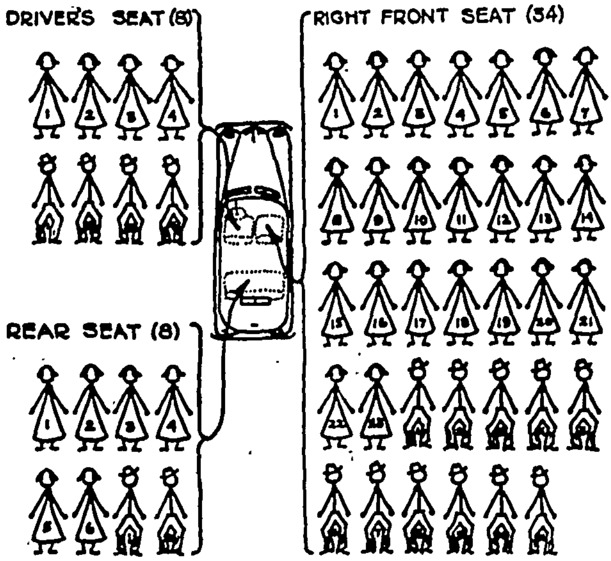

Fig. 1.—This chart shows the position in the car of 50 consecutive persons that consulted me for treatment of facial injuries. Eight were drivers; 8 were in the rear seat; 34 were in the guest passenger seat. Twenty-five of these were women.

"Guest passengers" in the front seat beside the driver are on the contrary in the most dangerous seat in the car because of their unprotected position in case of sudden stops. Children sitting on mothers' laps or standing in the front are frequently injured and occasionally killed when sudden stops cause crushing injuries on the dashboard. Occupants of the "death seat" are injured in the proportion of about 3 to 1, as compared to drivers (figs. 1 and 2). Some years ago I investigated 50 consecutive patients with facial injuries from automobile accidents who came to the clinic for plastic surgery. About 70 per cent were young girls and women who had been riding beside the driver in the front seat. They had various types of "guest passenger" injuries (fig. 1).

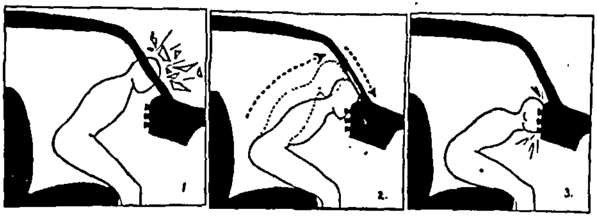

Fig. 2.—Three typical types of guest passenger injuries: Type 1. The head is thrown up forward breaking the windshield; head and neck cuts usually result. Type 2. Combination windshield cuts and crushing facial injuries result from these glancing blows. Type 3. Crushing and tearing injuries result from contact with gadgets on the instrument board.

With the advent of better roads and high speed transportation, guest passenger injuries are becoming even more numerous and severe, and deaths more common. To determine more accurately the seriousness of the problem, I secured the cooperation of Inspector Louis J. O'Brien, head of the Accident Prevention Bureau of the Detroit Police Department, who kept a record of all the passenger car accidents involving personal injuries during September 1947. These statistics support former conclusions (as derived from a study of figure 1) and show an even more serious picture from the passenger's standpoint (table 1).

TABLE 1.—*Comparison of Injuries to Drivers and to Passengers in Private Passenger Cars, September 1947**

Accidents 444 Cars Involved 480 Injured 633

	Number Cars	Drivers Injured	Passengers Injured
Driver Alone	178	178	---
Driver with Passengers	13	13	0
	219	0	260
1. Passenger	168	52	159
2. Passengers	62	15	81
3. Passengers	44	11	71
4. Passengers	15	2	26
5. Passengers	9	2	20
6. Passengers	3	1	11
7. Passengers	1	0	4

*Compiled from a report of the Accident Prevention Bureau, Detroit Police Department.

According to Detroit traffic engineer surveys, in normal traffic, in 61 per cent of cars the driver was alone. No one had ever kept statistics (so far as I can determine) on the number of cars involved in accidents that were driven alone. This information was vital in the study of the guest passenger problem and therefore was considered in the one month survey made for me by Inspector O'Brien.

The One Month Survey of Accidents

This survey shows that in 178 of 480 cars, 37 per cent, the driver was the sole occupant (table 2). One hundred and forty drivers suffered body injuries; 85 head injuries, and 36 injuries to both body and head.

From the Straith Clinic for Oral and Plastic Surgery.

A startling contrast is shown by the fact that in 219 accidents involving multiple occupants, 260 passengers but no drivers were injured! There were only 13 accidents in which drivers were injured but passengers remained unharmed, [1] (table 1).

These figures emphasize the great danger to passengers in the "death seat" and the need for better interior design in automobiles to reduce this hazard.

TABLE 2.—*Comparison of Injuries as Related to Location in Car**

	Total Injuries	Head Injuries	Body Injuries	Both Injuries
Drivers	261	85	140	36
Passengers in front	248	99	122	27
Passengers in rear	124	42	67	15

*Compiled from a report by the Accident Prevention Bureau, Detroit Police Department, on injuries sustained in private passenger car accidents, September 1947.

Since this study is devoted especially to injuries of guest passengers occupying the front seat, it is noted that 372 persons were injured in 289 cars carrying passengers. Two hundred forty-eight, or 69 per cent, of these were riding in the front seat. More than one half of these suffered head injuries. It is this group that I wish to refer to in particular.

Head Injuries

Head injuries are caused when the passenger is thrown forward: (*a*) into the windshield (type 1); (*b*) into the windshield, the head being deflected downward on the dash (type 2); (*c*) directly against the dash (type 3) (fig. 2).

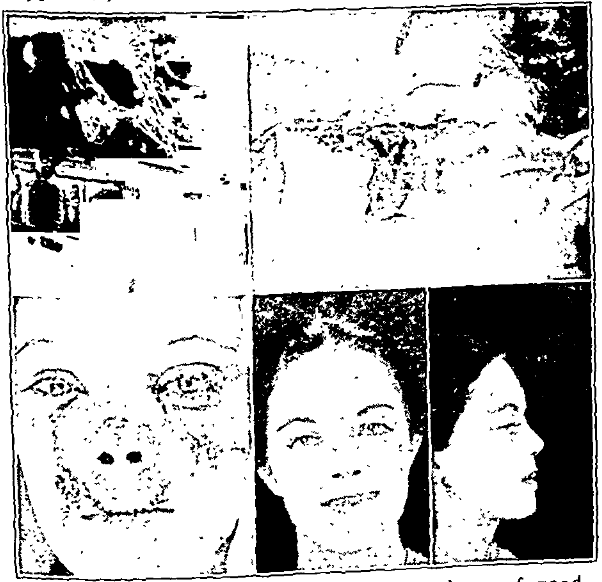

Fig. 3.—This guest passenger's head was forced through the windshield and the nose and upper lip were almost severed. Front and profile views show patient after scar excisions and insertion of preserved cartilage transplants to rebuild the nose.

Type 1.—The head frequently crashes through the windshield and the face comes in contact with jagged glass. Almost complete decapitation has been known to occur in this type. Forehead injuries are numerous and cuts in the upper and middle third of the face are most common (fig. 3). Frequently the nose is severely lacerated or a portion may be severed. Portions of the forehead, cheek or ears may be similarly detached by jagged glass.

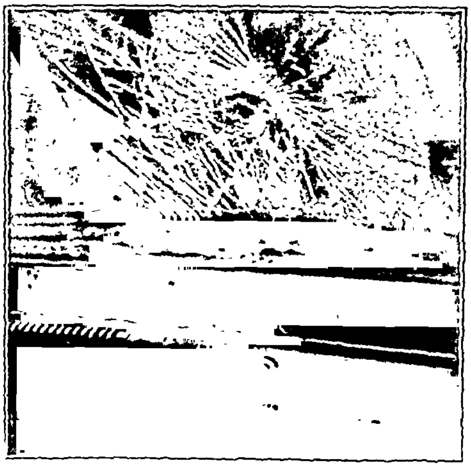

Fig. 4.—Type 2 injury. In this car the guest passenger was riding in a funeral procession at 20 miles per hour. A sudden stop caused her head to hit the windshield, cutting her forehead and causing her nose to be cut and crushed on the sharp edge of the dash.

Type 2.—Glancing blows from the windshield to the dash often cause both cutting and crushing injuries. Excessive speed is not always a factor, as evidenced by the patient who was riding in a funeral procession at the rate of only 20 miles (32.2 kilometers) per hour (figs. 4 and 5). Knobs, cranks, sharp ledges, etc., on the dash often do considerable damage in this type. Teeth are frequently dislodged in children and adults and many facial lacerations sus-

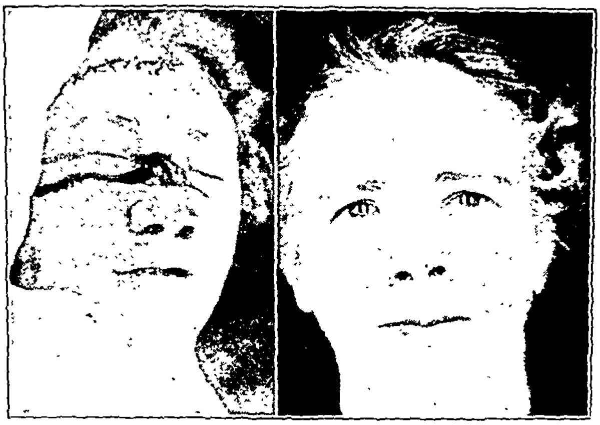

Fig. 5.—This patient hit the windshield and came down with crushing force on the sharp edge of the dash. Wounds were sutured by Dr. Richard E. Straith with subcuticular stitches (after removing emergency interrupted sutures shown in first photograph). Crushed nasal bones were supported by my special splint, which was fixed to a head cast.

---

[1] The complete detailed police report will be furnished by me on request.

tained by contact with dashboard projections (fig. 6).

Type 3.—Infants and children are often injured and occasionally killed by crushing impact of skulls or faces on the dash. Teeth are frequently knocked out and faces cut on projecting knobs, cranks, "drop open" ash trays, etc. In more severe impacts the nose is frequently crushed; the malar and the upper jaw are frequently fractured, leaving pronounced facial deformities (figs. 7, 8 and 9).

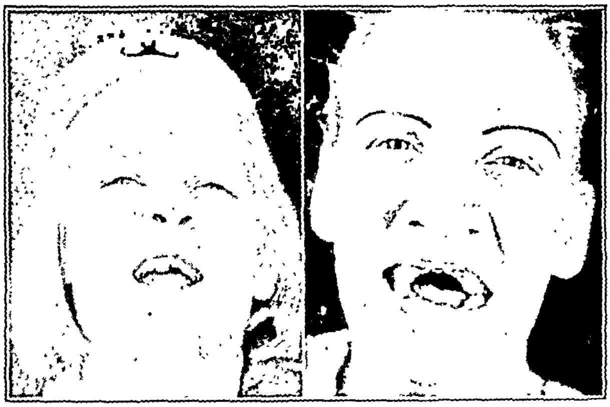

Fig. 6.—Children are in the most dangerous position in the car when riding on mother's knee or standing up in front. Frequently childrens' teeth are broken off by hitting the dash in sudden stops, as happened to this child. The adult suffered a type 2 accident, her mouth coming down on a radio knob on the dash. Such projections should be eliminated and the dash should be crash padded to avoid such injuries.

Figure 9 shows the rather typical result of an accident. Note the slight steering post injury sustained by the driver (cut on chin) whereas the guest passenger received a crushing injury due to her impact on the dashboard.

Enforcement, Education and Engineering

For years traffic engineers have been talking about "engineering" with the three "E's": enforcement, education and engineering. To reduce this staggering toll of accidents and deaths, there must be cooperation in these phases.

Enforcement.—There must be enforcement of speed and other necessary traffic regulations. In all traffic surveys, speed is still rated as the greatest cause of accidents.

Education.—Since the age group from 18 to 24 produces the greatest number of accidents, education of youths at high school age is of paramount importance. Boys especially should be shown that, as drivers, they are in the safest seat in the car! What poor sportsmanship it is to drive recklessly and endanger the lives and faces of young girls who are usually the unlucky "guest passenger" victims!

There is no doubt, from the records of the patients at the Straith Clinic, that drinking was responsible for many accidents. Even distillers themselves advise every one to abstain from drinking for at least two hours before driving. If this rule were followed fewer accidents would result.

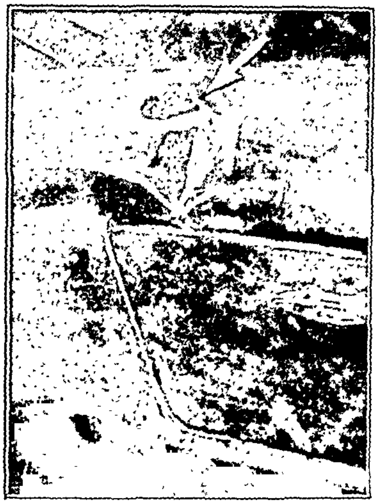

Fig. 7.—Type 3 injury left the impression of this woman's upper teeth in the instrument panel. At one point (arrow) a tooth actually penetrated the steel dash. The facial bones were crushed almost to pulp. Note deformity resulting as shown in figure 8.

Mothers should know that babies held on their knees occupy the most dangerous place in the car. They should hold children firmly if riding in the front seat or place them in proper carriers. Children should be kept from standing in the front (if possible, though I am well aware of the difficulty in doing this).

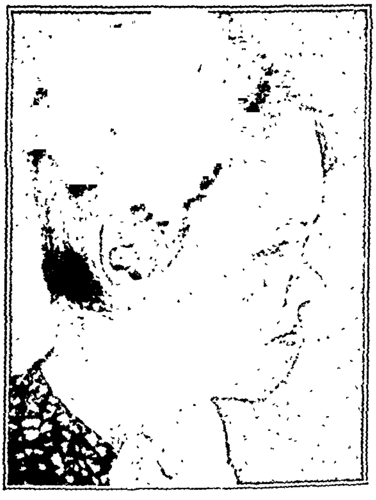

Fig. 8.—Practically all the facial bones were fractured due to the impact on the dash as shown in figure 7. In spite of all efforts to maintain the fragment in position, this deformity resulted.

Engineering.—For the protection of the drivers, collapsible steering posts have been advocated. The horn rim could be placed on the underside of the wheel to prevent injury to face or chest in case of breakage. Raising and padding the lower edge of the dash would lessen knee injuries, and fewer floor pedals might minimize ankle injuries.

Since it is obvious that "guest passengers" are in the most dangerous position in automobiles, more attention should be paid to safety features in this part of the car.

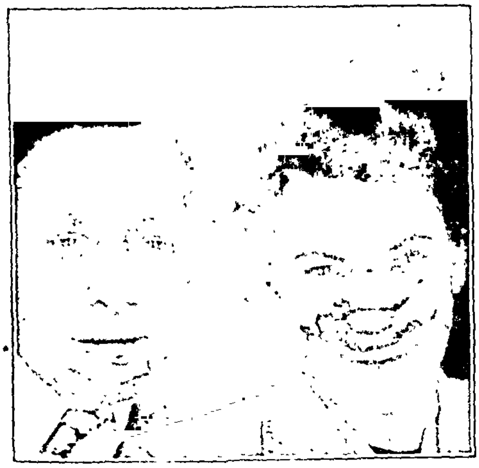

Fig. 9.—These patients were forced off the road by an oncoming drunken driver. Though they had almost stopped, they hit a parked car. Note the typical slight chin injury sustained by the driver ("steering post injury") and the crushing "guest passenger" injury sustained by his wife, whose face struck the dash.

I have advocated[2] the removal of all knobs, cranks, drop down ash receivers, sharp ledges, etc., from the dash and the incorporation of rubber crash padding in front of the guest passenger. (Elimination also of sharp ash receivers and heavy robe rails and other attachments from the back of the front seat and provision of padding for the back edge of the front seat would minimize injuries to passengers in the back seat, who are frequently thrown forward.)

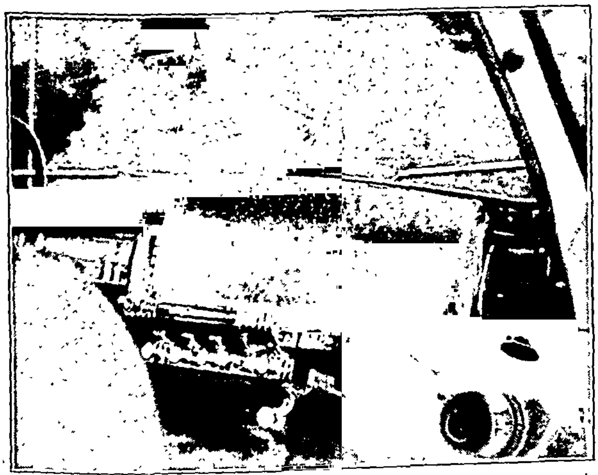

Fig. 10.—This is the latest model of my crash pad which I have used for years on my cars. It can be adapted to any car, is hinged at the top for easy access to the glove box and offers adults and children much protection.

Hinging the windshield so that it would be forced outward by a force just short of the glass breaking point has been suggested. This would substitute the danger of a passenger's going through the opening and is therefore of questionable value.

For many years I have used, in my cars, a detachable crash pad to cover the dash in front of the guest passenger. If such a device were in common use, or crash padding incorporated in the dashboard, the facial injuries described would be reduced immensely (fig. 10). Children could ride in the front seat with less danger and with infinitely less anxiety on the part of the parents (fig. 11). Fortunately some car manufacturers are becoming more aware of these dangers to the guest passenger and are eliminating dangerous projections from the dash. Some are at long last adding crash padding to the instrument panel. It is hoped that others will follow suit to help reduce the staggering toll of accident victims.

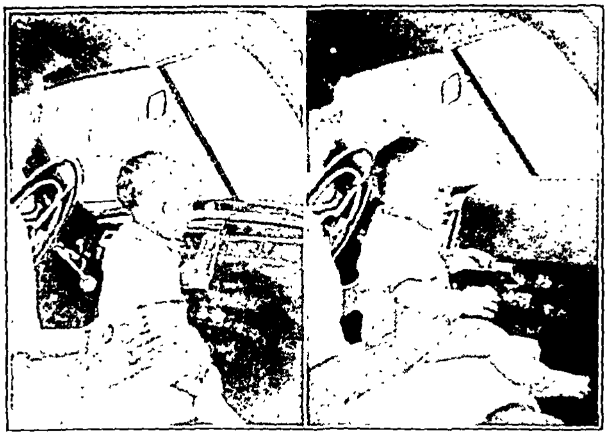

Fig. 11.—Babies on mothers' knees are in the most dangerous place in the car. Many have been killed by sudden stops, crushing their heads on the dash. The second photograph demonstrates the protection which children and adults should have when the crash pad is covering the dash.

Pneumonic Plague.—Rangoon has been "infected" off and on for the last quarter of a century, the reserviors being rats and bandicoots. The pneumonic form, however, is rare. When recaptured in May, 1945, Rangoon was a severely devastated city and rehabilitation proceeded slowly... Optimal conditions existed for the multiplication of rodents, and experienced observers were of the opinion that rats and bandicoots had never been so prevalent. Plague infection was confirmed among both species in 1945, but no sign of an epizootic was found. Human cases of bubonic plague in the city numbered 151 between May, 1945, and mid-August, 1946. The city was free from infection from the middle of August until late September, 1946. The village where the present outbreak began had shared in the bubonic epidemic in the spring, 17 cases being reported up to early April. Since that time the village also had been free from the infection. Pneumonic plague was not suspected until 10 persons had died, largely because the health authorities did not know the facts until a late date. The initial focus was the compound of a small soap factory in a village on the fringe of the city.—Wynne-Griffith, G., Pneumonic Plague in Rangoon, *Lancet*, April 24, 1948.

TULAREMIA IN THE OZARKS REGION

LIEUTENANT (jg) ROGER B. BOST
Medical Corps, United States Naval Reserve
CAPTAIN S. C. PERCEFULL
Medical Corps, Army of the United States
and
HOWELL E. LEMING, M.D.
Fayetteville, Ark.

In 1944 Heilman[1] demonstrated the sensitivity of Pasteurella tularensis to streptomycin under experimental conditions, and fifteen months later its clinical use in tularemia was reported by Foshay and Pasternack,[2] who noted the rapid regression of symptoms in 7 patients with ulceroglandular tularemia. Pulaski and Amspacher[3] reported successful treatment with streptomycin in 10 cases which occurred in United States Army hospitals, and Hunt[4] reported 12 cases of pleuropulmonary involvement in which streptomycin therapy was used, with prompt recovery in all except 1 case, in which death was attributed to pulmonary embolus. Seven cases of laboratory-acquired infection, successfully treated by streptomycin, were presented by Howe.[5] The National Research Council reported the treatment of 67 patients with 63 recoveries.

Before streptomycin became available, 27 patients with tularemia were seen at this hospital, and subsequently 27 patients have been treated with streptomycin. The purpose of this paper is to summarize the outstanding features of these 54 cases.

EPIDEMIOLOGY

The incidence of tularemia in this Ozarks region is increasing. In the interval from 1936 to 1940, 7 cases were recorded. From 1941 to 1944, 9 cases were seen and from 1945 to date 38 cases have been treated. Twenty cases have been seen thus far this year. Forty-one of the patients came from Northwest Arkansas and 13 from Southwest Missouri.

There was a definite seasonal incidence among these cases. Cases occurred during every month of the year; however, contrary to the observations of some authorities, 55 per cent occurred during May, June and July.

In contrast with statements concerning the most usual sources of the disease and the mode of transmission, it has been observed here that the source of the disease in 63 per cent of these cases was tick bites; in 14 per cent it was contact with rabbits, and in 4 per cent contact with squirrels. One patient gave a history of sticking a thorn in his finger at the site where the primary ulcer developed subsequently. The source of infection in 18 per cent of the cases was unknown. It was interesting to note that in each instance in which contact with an animal was considered the source of the infection, the patient gave a history of having had an abrasion at the site of the primary lesion previous to contact with the animal.

The incubation period, when it could be determined, varied from one to twelve days; however, 62 per cent were from one to three days. Five patients found ticks on their bodies at the site of the ulcer on the day of onset of symptoms. One unusual case presented an ulcer on the glans penis, hidden by the prepuce, with a tick imbedded in the center of the ulcer crater, of which the patient was unaware.

SYMPTOMS

The symptoms most commonly observed were malaise, chills, fever, generalized aching, anorexia, headache, sometimes nausea and vomiting and occasionally delirium. Rarely a rash of variable type appeared. The maximum temperature varied from 100 to 105 F., the average being 103 F. In most cases it remained more or less continually at a high level until the proper therapy was instituted. In some cases it exhibited regular remissions as seen in brucellosis. The pulse rate was usually proportional to the fever. The sedimentation rate was elevated, and in most cases there was leukocytosis. The white blood cell count ranged from 5,000 to 20,000, the average being 12,000. The differential white blood cell count was usually normal, but sometimes showed an increase in polymorphonuclear leukocytes. The spleen was sometimes enlarged.

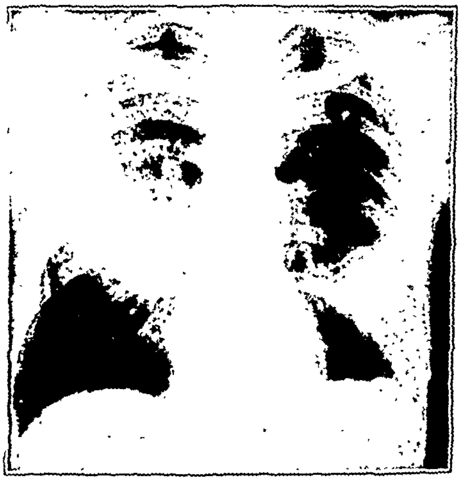

Fig. 1.—Severe bilateral tularemic pneumonia with fatal outcome.

The site of the tick bite or contact with the animal was most commonly on the extremities with regional adenitis, with the lesions occurring as frequently on the lower extremities as on the upper. Ulcers did occur on the scalp, chest, abdomen, in the axillas and frequently on the penis or scrotum. In half of the cases with ulcers of the upper extremities epitrochlear adenitis developed. The unusually high frequency of the ulceroglandular pathologic changes occurring in the lower extremities, genitalia and abdomen (50 per cent) was undoubtedly due to the fact that ticks frequently attach themselves to the lower portions of the body.

Types of Tularemia

	Number of Cases	Percentage
Ulceroglandular	37	70
Pneumonitis alone	9	17
Typhoidal	1	0.5
Glandular	3	5.5
Oculoglandular	2	3.5
Ulcer alone	2	3.5
Total with pneumonitis	16	30

The cases of ulceroglandular and oculoglandular disease were *nearly always correctly* diagnosed promptly. In many cases, even before the reaction to the agglutination test was reported positive, the diagnosis had been made and the therapy started. However, the diagnosis

in the cases of other types of the disease, particularly the pneumonic and typhoidal forms, was frequently delayed until therapeutic measures (e. g. penicillin for the cases of pneumonic disease) had failed and agglutination tests were done.

Case 1.—The patient, a farmer aged 21 years, was admitted to the hospital in an acutely ill condition, complaining of pain and swelling of the left eye and eyelid. A few days prior to admission he had experienced general malaise, and twenty-four hours later the left eyelid and periorbital region began to swell, associated with fever. He had found several ticks on his body a few days prior to the illness, but he did not recall having been bitten, and was not in contact with animals. He was not aware of having had a foreign body in the eye.

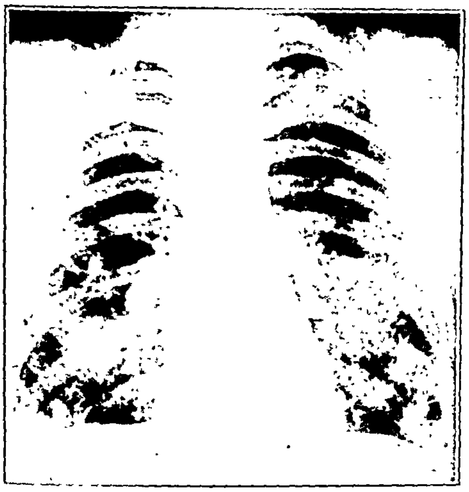

Fig. 2.—Tularemic pneumonia; rapid recovery occurred under streptomycin therapy.

Physical examination disclosed an acutely ill patient with a swollen and diffusely red left upper eyelid. The conjunctival surface of the lid exhibited a yellowish adherent membrane; the conjunctiva was red and edematous and the eyeball itself showed superficial injection. The fundus was not visible because of vitreous opacity. The right eye appeared normal. There was moderate edema of the left lower part of the face and upper part of the neck with pronounced cervical adenopathy. The temperature was 103 F. and the pulse rate 80. The white blood cell count was 7,100, with 70 per cent neutrophils and frequent smears and cultures of the eye were negative. A roentgenogram of the chest was normal, as was the urine. Because of suspected diphtheria, the patient received diphtheria antitoxin, which proved of no value, and his temperature ranged in a daily peak from 102 F. to 104 F. Six days after admission the agglutination reaction for tularemia occurred in a dilution of 1:80, and one week later it occurred in a dilution of 1:1,280. He was started on 0.4 Gm. of streptomycin every four hours, and the temperature immediately fell to normal, where it remained. The ocular symptoms subsided dramatically, but several cervical nodes became fluctuant, requiring surgical drainage. The streptomycin was continued until a total of 14 Gm. had been given. Recovery has been complete.

DIAGNOSIS

The definite diagnosis of tularemia depends on the agglutination tests. In many cases the serologic reaction was positive in high dilutions on the first examination. Any definite agglutination, even in the lowest titers, is significant; however, a positive diagnosis depended on a high or a rising titer. The highest titer among these cases was 1 to 42,240. Cross agglutinations in low dilutions with Brucella antigens were sometimes observed. It is commonly believed that the agglutination reaction becomes positive in the second week of the disease, but it was noted here that this interval varied widely. The interval ranged from eight to forty-three days, the average being fourteen days. In one fifth of these cases the agglutination reaction did not become positive before three weeks. Streptomycin did not appear to inhibit the development of specific antibodies.

TREATMENT

In April 1946 streptomycin became available for use at this hospital under the supervision of the National Research Council.

The course and prognosis of tularemia has been greatly affected by streptomycin. Prior to April 1946, 27 cases of tularemia had been observed, and since that time streptomycin has been used in 27 cases. Previous to this form of therapy, the morbidity after admission to the hospital varied from five to forty-five days, the average febrile period being fourteen days. Treatment varied, but in some cases included serum therapy and intravenous administration of bismuth sodium tartrate in addition to supportive care. In these 27 cases the mortality rate was 11 per cent. Twenty-two per cent of the patients had pneumonia, half of whom died. In addition to this long morbidity and high mortality convalescence required months, and relapses were common.

When streptomycin was used the morbidity dropped to an average of one day; with a maximum of six days. In most cases when a therapeutic blood level was attained, fever and other symptoms subsided dramatically. One patient was extremely ill and irrational on admission, and a history could not be obtained. Within twenty-four hours after treatment with streptomycin was started he had improved so dramatically that his only remaining complaint was weakness.

Of the 27 patients treated with streptomycin, 10 had pneumonia, and there were no deaths. In a few of these cases streptomycin was started before the agglutination test became positive in result. It is important to realize that the course of the illness may be far advanced before the agglutination becomes positive. Thus in cases of atypical pneumonitis in this region, in which a tularemic etiology is suspected, the use of streptomycin may be justified in face of a negative agglutination reaction, particularly when other antibiotics have failed.

Case 2.—A white farmer aged 28 years was in good health when he cleaned a rabbit, seven days before he entered the hospital. At that time he had a small abrasion on his left index finger. Two days later he noted pain, swelling and purulent drainage about the abrasion, associated with swelling and tenderness of the epitrochlear and axillary lymph nodes. When seen by his family physician he had a temperature of 103 F. and had vomited several times. The physician administered sulfonamide compounds and salicylates; however, the symptoms continued until admission here.

Examination revealed an acutely ill, febrile patient. His temperature was 101 F., his pulse rate 90 and his respiration rate 24. The skin was hot and dry. There was a small tender, crusted abrasion on the dorsum of the left finger which was swollen and inflamed. There were several large, soft, tender epitrochlear and axillary lymph nodes on the left side which were freely movable. The heart, lungs and abdomen were normal.

The initial impression was tularemia of the ulceroglandular type. The patient's temperature rose to 103 F. A roentgenogram of the chest was normal, and on the day after entry the agglutination test for tularemia was negative in reaction. Two days later the reaction was still negative; the patient was started on specific therapy and within twenty-four hours his temperature had declined to 99 F.; it remained below this level thereafter. On the sixth day the agglutination reaction was still negative, but on the following day (i. e., fourteen days from the onset of symptoms) it became positive in a dilution of 1:10. Six days later it became positive in a dilution of 1:1,280. The patient had recovered long before and was discharged cured.

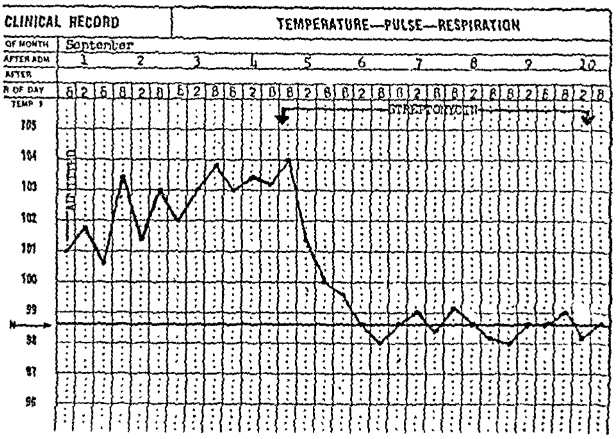

Fig. 3.—Temperature graph illustrating rapid response to streptomycin in a case of severe ulceroglandular tularemia.

Because the optimum dosage of streptomycin had not been established, dosages were varied according to the type and severity of the disease and the patients' response to therapy. The most common schedule was 1.0 to 1.25 Gm. daily in divided doses every three or four hours. A few cases, in which the desired response was not obtained on this program, exhibited prompt resolution of symptoms when medication was increased. Total dosage in cases of ulceroglandular disease varied from 3.75 to 14 Gm., the average being 7 Gm. Three patients received only 5 Gm. with good results. In the pneumonic forms the average dose was also 7 Gm., with a range of 5 to 14 Gm. Likewise, 3 patients with pneumonia were treated satisfactorily with 5 Gm. of the drug. Results obtained from the various dosage schedules were all essentially the same; i. e., excellent.

The resolution of the pneumonic process is slow regardless of treatment with streptomycin. This drug stopped the extension of the pulmonary pathologic changes, but the process of resolution usually required two to three weeks, and occasionally a residual fibrosis remained indefinitely.

Healing of the tularemic ulcer begins soon after treatment with streptomycin is started and is usually complete within one week. In some cases there was a secondary infection which responded to moist dressings. In most of the cases the affected regional lymph nodes healed slowly, but not infrequently they became fluctuant, and if not incised would, many times, remain abnormal for several weeks, rupturing spontaneously. It was found that surgical drainage reduced the healing interval considerably.

SUMMARY

An analysis of 54 cases of tularemia is presented. The incidence of the disease appears to be increasing in this Ozark region. The majority of the cases occurred during the summer months. In 63 per cent of the cases the source of the infection was tick bites.

The incubation period varied from one to twelve days but averaged one to three days. The symptoms in these cases did not vary significantly from the usual description. One or more cases of each type of the disease were seen, with 70 per cent representing the ulceroglandular form. Seventeen per cent of the patients had pneumonic involvement.

The definite diagnosis of tularemia depends on a positive agglutination reaction in either a high or a rising titer. The interval from onset of symptoms to the development of specific agglutinations ranged widely from eight to thirty-three days, with an average of fourteen days.

Twenty-seven cases in which treatment was with streptomycin were compared with an equal number of cases in which treatment was only symptomatic. An average morbidity of fourteen days and a mortality of 14 per cent were noted in the latter group, in contrast with an average morbidity of one day and no mortality in the cases in which treatment was with streptomycin. Previous to the use of streptomycin 50 per cent of the cases of pneumonic disease were fatal.

The indications for the use of streptomycin do not necessarily include a positive agglutination reaction, because the course of the illness may be far advanced before this test elicits a positive reaction. Thus, in this region, the ulceroglandular syndrome with fever is in itself an indication for immediate specific therapy.

The most common dosage schedule was 1 to 1.25 Gm. of streptomycin daily in divided doses every three or four hours, the total usually amounting to 5 to 7 Gm. It was noted that the average case of pneumonic disease required little, if any, more streptomycin than the cases of ulceroglandular disease.

PERMANENT WAVE PROCESS

Clinical Report With Special Reference to the Effect of Ammonium Thioglycolate on the Skin

LEON GOLDMAN, M.D., LESTER MASON, M.D.
and WILLIAM McDANIEL, M.D.
Cincinnati

It has been estimated by manufacturers of chemicals employed in permanent hair-waving procedures that some "permanent wave process will be carried out at least fifty million times during the current year."[1] There is then, an apparent need for a critical study of the irritant properties of the chemicals so casually applied to the hair and scalp.

Permanent hair-waving methods are classified by Reed, Humoller and DenBeste[1] into two main categories. Briefly, in the "hot method, the hair is treated with an alkaline sulphide preparation and wrapped around a rod of small diameter. Heat is then applied to change the configuration of the hair from a straight to a curled state." In the "cold method, the hair is also wrapped around a rod of suitable diameter either prior to or after treatment with an alkaline reducing agent—usually thioglycolate. In contra-distinction to the hot permanent waving method, no external heat is applied. After satisfactory undulation of the hair is obtained, the wave is fixed by application of a suitable oxidizing agent."[1]

The mechanism of the latter waving reaction and the supposed changes in the chemistry and structure of the hair under these circumstances provide an interesting example of the application of biochemistry in dermatology. However, clinical interest at present derives chiefly from the possibilities for injury to the hair and the scalp which may accompany the procedures of cold waving. Many clinical and experimental reports have appeared in the literature, and some of these

have been confusing and contradictory. This situation illustrates once more a principle that all too frequently is neglected, that the potentialities for harm possessed by commercial products should be fully investigated before they are distributed and used. Rattner[2] has indicated that there have been only about twenty-two complaints among 50,000 treatments.

Cotter[3] reported 5 cases of dermatitis associated with the application of cold waving processes. Patch tests were carried out on 2 of these persons, but the details of the concentrations of the materials employed were not given. McCord[4] has reported that certain commercial preparations of ammonium thioglycolate caused injury to the skin of 7.4 per cent of persons subjected to contact therewith for twenty-four hours, but no injury resulted from similar contact for four, six or nine hour periods. McCord[4] is also authority for the statement that no primary irritation of the skin occurs as the result of contact with thioglycolic acid or its alkaline derivatives in concentration (in water) below 8 per cent by volume. Moreover, McCord[5] found no evidence of sensitivity or allergic response of the skin to carefully prepared ammonium thioglycolate. According to Cappel and Cappel,[6] the incidence of injurious effects, in the wake of thirty million or more cold waves that have been given within three years, has been under 0.1 per cent. These investigators applied cotton saturated with the material to the skin and covered it with a watch glass, the edges of which were sealed on the skin with collodion. Goodman[7] claimed that the patch test is not reliable for the detection of dermatitis from cold wave preparations, since the factor responsible for the irritation is usually a combination of thioglycolic acid, the softener, the fixative or the keratin, rather than the thioglycolic acid itself. Howell[8] reported a case of eczematous contact dermatitis following the application of a cold waving process. No positive reaction was observed when waving solution, neutralizing liquid and shampoo were employed individually in patch tests. He also carried out patch tests, with negative results, on 3 normal persons with 1 per cent concentrations of the shampoo, preliminary lotion, waving compound and neutralizing solution, and mixtures of these chemicals. When the patient was tested with the preliminary lotion, one month after the dermatitis subsided, a positive reaction was elicited in twenty-four hours. This preliminary lotion was a special type of detergent of unknown composition, used to cleanse the hair. McGill and Rag[9] wrote that 11 cases had been reported to the Division of Industrial Hygiene in Oregon and that none of the diagnoses had been confirmed. One patient had failed to respond positively to a patch test with the cold waving solution diluted with 100 parts of water. In a second case reported by these authors patch tests were not made.

In addition to the possibility of cutaneous irritation and sensitization from thioglycolate, there are, of course, some definite effects on the hair. The changes include drying, splitting, changes in tensile strength, elasticity and, of course, cellular state. Clinically, these changes may be manifested by changes in the color of the hair; for example some darkening of white hair; and by splitting, cracking and desiccation of the hair. It does not matter how correct or "mild" the permanent waving process may be, there still are a number of changes in the hair, which, for this reason, is not in a normal state after the cold waving process.

Systemic toxicity from cold waving must also be considered. Cotter[3] has suggested this in his report, but he gives no evidence of its occurrence. Some detailed observations have been made on animals in this regard. According to Whitesell, Alvarez and Draize,[10] salts of thioglycolic acid may be absorbed percutaneously by animals with resultant systemic poisoning, "but the dose level is higher and the manner of application more vigorous than those specified in directions accompanying waving solutions intended for use by beauticians and in home application." There were minor fluctuations in the hemoglobin content of the blood and in the volume of erythrocytes of animals following dosages as small as 4 cc. per kilogram per day. In general, however, the conclusion arrived at from these studies was that ammonium thioglycolate hair-waving solutions are "safe" for use if the usual directions are carefully followed. Rostenberg,[11] who has had considerable experience with the analysis of reports of irritations from consumer products, expressed the belief that many prefer the cold wave to the discomforts incident to their use.

Since the cold wave process as practiced in the beauty parlor is an elaborate ritual, which involves the application of many things in addition to the thioglycolate solution, the correct analysis of any irritation presumed to have followed use of the cold waving process demands multiple cutaneous testing with all the ingredients used in the various steps of the cold waving process. These should include: (1) the preliminary shampoo material, (2) the preliminary cleansing lotion, (3) the cold wave material, (4) the oxidizing agent, (5) the post-treatment shampoo material, (6) the wave setting material, perfumes, etc.

EXPERIMENTAL OBSERVATIONS

Preliminary observations have been made to determine the effect of the application of undiluted and diluted ammonium thioglycolate on the normal scalp and the normal skin of women. For this purpose 149 women patients with apparently normal skin and scalp were employed as subjects. Thirty of these were Negro. Small quantities of the undiluted ammonium thioglycolate were sealed by means of paraffin into a series of small bottles for use as required. In an effort to approximate the conditions under which the cold waving procedure is carried out, 1 drop of the undiluted ammonium thioglycolate solution was applied by means of a glass rod and rubbed into the occiput, while another drop was rubbed into the clear skin of the forehead just below the hair line, this procedure being designated as a "streaking technic." On the same occasion, in many instances, a conventional contact patch test of the undiluted material was made, the observations on these being concluded in forty-eight hours.

The results of the unstandardized "streaking tests" were disappointing, even though an occasional positive reaction was obtained. There was no correlation between such reactions and the positive reactions to the patch tests. Conversely, the subjects with the positive reactions to patch tests gave negative reactions to "streaking tests." It is believed however, that if the "streaking test" could be standardized as regards pressure, temperature and the duration of actual contact with the skin, information concerning the applicability of the test of the properties of chemical substances could be obtained.

TABLE 1.—*The Results of the Application of Ammonium Thioglycolate Solution to the Skin of Human Subjects by a "Streaking Technic"*

Material Tested	Number of Subjects	Reactions				
		Negative	Positive			
			+	++	+++	++++
Undiluted ammonium thioglycolate, scalp	83	81	0	2	0	0
Undiluted ammonium thioglycolate, forehead	83	83	0	0	0	0

The eleven reactions obtained in routine forty-eight hour patch tests carried out on 83 patients suggest that this compound is a mild irritant for the skin when applied in undiluted form over a prolonged period of time.

Twelve beauty parlor operators with contact dermatitis of the hands were examined. In general, the majority of these cases showed the irritant type of contact dermatitis, with solitary, thickened, fissured and occasionally vesicular, oozing patches. It is important, that in no case was a positive reaction produced to a patch test with the cold wave material which the beauty parlor operators furnished. Tests with the shampoos gave positive reactions with much greater frequency. This observation substantiates a clinical impression that the majority of cases of dermatitis related to cold waving materials are characterized by direct irritation or even nonallergic eczematous dermatitis (Baer) and not sensitization. In view of the prolonged periods of contact associated with friction which the beauty parlor operator has with these solutions, it is strange that not more of these reactions are produced. In cold waving done in the home, where 1 person does the hair of a number of subjects, the hands of the operator may also become irritated.

TABLE 2.—*Results of Application of Ammonium Thioglycolate Alone and After Admixture with Soap Solution to Scalp and Skin of Human Subjects by a "Streaking Technic"*

Material Tested	Number of Subjects	Reactions				
		Negative	Positive			
			+	++	+++	++++
Undiluted ammonium thioglycolate, scalp	63	61	2	0	0	0
1% soap solution, scalp	63	62	1	0	0	0

Undiluted ammonium thioglycolate, forehead	63	63	0	0	0	0
1% soap solution, forehead	63	63	0	0	0	0
Undiluted ammonium thioglycolate plus 1% soap solution, forehead	63	63	0	0	0	0

Five patients with dermatitis presumed to have followed cold waving of the hair were studied. In 1 instance, the cutaneous reaction followed the use of a "hot" waving solution. In no case was an extensive eczematous type of reaction produced. The clinical forms of dermatitis which may follow the cold waving process may be divided roughly into three classes: (1) a pruritic, discreet, papulopustular and vesicular eruption scattered over the back of the scalp, about the ears and about the shoulders; (2) the solitary deep burn type of lesion (more common in "hot" waving?). If this is deep enough alopecia may result; (3) rarely, an eczematous contact dermatitis of the hair line and occasionally of the scalp.

No effort was made to gather the details of the performance of the operators of the cold waving processes carried out on these patients, with regard to carelessness, expertness, precautionary measures and the period of contact permitted. The shampoo was implicated most frequently by the patch tests, and in some instances no positive reactions to any of the substances were obtained. There is definite need for a critical study of the irritation of the skin of the beauty parlor operators who work with cold waving solutions, and also of patrons of beauty parlors who complain of various degrees of cutaneous irritation following the use of cold waving solutions. It is our impression from clinical observation that irritation of the skin, while uncommon, is yet more frequent in its occurrence in this relationship than is eczematous dermatitis. Considering the strength of the solutions employed in cold waving process, it is indeed surprising that more cases of cutaneous irritation do not result.

COMMENT

From preliminary observations, then, it is evident that the technic of cold waving can produce local irritation of the skin. Some persons appear to be more susceptible to this irritation than others. Some factors which may be considered are the differences in the materials employed and the technics of their use. These factors have not been determined in a critical fashion. Rarely, eczematous hypersensitivity may be produced in the cold waving process. It seems that this eczematous hypersensitivity is more frequently due to materials other than the cold waving solutions themselves and, as Peck and Schwartz[12] mentioned, especially the perfumes, gums and resins. Preliminary use of thioglycolate in the foregoing series of cutaneous tests has demonstrated that it is, potentially, a mild irritant for the skin.

These few facts suggest that it may be possible to develop some prophylaxis of irritation from thioglycolate. When the material is used with considerable caution, there may yet be some dermatitis about the neck from the seepage of ammonium thioglycolate between towels and the surface of the neck and from the rubbing of this into the skin. Similarly, the dermatitis of the scalp may be due to unduly prolonged contact of the ammonium thioglycolate with the scalp, to inadequate removal of the material after its effect has been achieved or to its incomplete neutralization at the proper time.

However, the chief difficulty in the use of ammonium thioglycolate in relation to cutaneous damage lies in its effects on beauty parlor operators rather than on the patrons. The specific background of such irritation can rarely be proved by the diagnostic procedures available at present, since the lesions are nonspecific, being those of primary irritation. From a practical standpoint, it is not possible to protect the skin of beauty parlor operators during their performance of cold waving technic, since the technic is an open and wet one, and the hands, especially the left, are dampened continuously by repeated applications of the solution. In addition, the frequent use of detergents associated with the process would appear to be a contributory factor. Beauty parlor operators refuse to use gloves, and the process at present does not appear to be amenable to control from the aspect of complete avoidance of contact on the part of the operators.

---

[12] Schwartz, L. B., and Peck, S. M.: Cosmetics and Dermatitis, New York, Paul B. Hoeber, Inc., 1946, p. 103.

The following recommendations are offered for the purposes of prophylaxis:

1. Attempts to prevent irritation from ammonium thioglycolate: The beauty operator should be instructed emphatically that no matter how rapidly she works and no matter how anxious she is to complete her work no large quantities of the cold waving materials should be allowed to remain on the surface of the skin, and that as far as possible none should be permitted to remain longer than is required to remove it from such skin surfaces as those of the neck and forehead, which are not covered with hair.

2. Ammonium thioglycolate adjacent to a scratch, or to an area which has been rubbed by towels or abraded by other manipulations of curling equipment or other appliances, may also serve to induce an actual dermatitis. Thorough rinsing of the scalp is recommended to prevent this so far as possible.

3. The operator should pay close attention to any complaints of burning and discomfort which the patient exhibits. Areas so involved can be and should be cleansed as completely as possible by mopping up the excess which has accumulated thereon.

4. Following the appearance of actual erythema or redness of the scalp or of the neck, further contact with the permanent waving solution should be avoided, since further contacts will certainly cause an increase in the irritation.

5. Towels and towel rests should be inspected from time to time to see whether any of the cold waving solutions have been allowed to drip or remain on them.

6. During the operation of cold waving, every attempt should be made to limit the use of materials to the least quantities consistent with obtaining the effect and to avoid spillage and undue spread of the materials.

7. The beauty parlor operator should attempt to protect her hands as much as possible during the cold waving operations: (*a*) by attempting to use materials and appliances which do not allow repeated contacts with her hands; (*b*) by avoiding undue dependence on the so-called protective cream; (*c*) by using protective gloves when necessary, especially if the skin of the hands should be irritated or abraded, and (*d*) by avoiding all contact with cold waving preparations or strong detergents for a "significant" period of time when the skin of the hand is irritated or thickened.

When actual dermatitis is found to have occurred in close or plausible time relationship to contact with cold waving materials, an effort should be made to classify the type of dermatitis. This is to say, one must decide whether the dermatitis is a discreet, localized irritation of the scalp and skin, what the degree of this irritation is and whether or not it is an eczematous type of contact hypersensitivity. Next, the patient should be tested carefully and adequately with all the materials that have been used in the entire technic of the cold waving process. As the result of the collection of such data on a sufficient number of cases, the true picture can be found and proper corrective measures outlined.

SUMMARY AND CONCLUSION

Cold waving solutions are used extensively, and the frequency of reactions is reported to be less than 0.1 per cent. The reactions may be characterized either as varying degrees of primary irritation or, more rarely, as instances of eczematous hypersensitivity. The reactions on the hands of the beauty parlor operators are more frequent by far, more severe and more extensive than those which occur among patrons of the beauty parlors.

In a preliminary group of observations on 149 women, ammonium thioglycolyate was found to be a mild irritant to the skin. Attempts were made to simulate actual practice by the use of "streaking tests" on the scalp and the forehead. There were a few reactions to this procedure, but these effects were not correlated with the response to a conventional forty-eight hour patch test.

Recommendations have been made for the avoidance of procedures on the part of the operators which would appear to increase the hazard of cutaneous irritation to patrons.

Little hope is held for the protection of the hands of the beauty parlor operators under the conditions associated with present procedures, unless they will consent to wear some sort of protective gloves.

VARIOUS PHASES OF THE USE OF STREPTOMYCIN IN TUBERCULOSIS

MAURICE L. COHN, Ph.D.
Denver

Streptomycin, a recently developed antibiotic, figures prominently at the present time in the chemotherapy of tuberculosis in man. During the twentieth century the development of chemotherapy in tuberculosis in man has been pursued by two apparently divergent sets of investigators: first, those who believed in conservative progress based on thorough fundamental scientific study of possible therapeutic agents, translating elucidating laboratory and animal findings into human values; and second, those who were content to quickly transpose apparently encouraging in vitro and in vivo animal findings into human significance. The second group, of course, took encouragement from findings in diseases where only human studies were possible and from the fact that animal disease did not duplicate sufficiently that noted in man and therefore did not permit the latter to be interpreted in the light of such scientific knowledge. Yet it is odd that the second group frequently justify their failures, both in interpreting human results and in supporting their contentions, on the basis of the results of animal tests.

There are definite features of streptomycin which preclude an early and ready evaluation of its effects in human tuberculosis, a disease from which man recovers with only the aid of nature and good medical sense to live his allotted three score plus ten. The investigations to be reported here were undertaken with the sole purpose of building scientific information that would enable us to determine whether streptomycin and similar chemotherapeutic agents might be beneficial in tuberculosis in man and, further, to explain so far as possible its mode of action in man. Much has been written to date on streptomycin, and that part published previously to the middle of 1946 has been reviewed by us.[1]

It is claimed that "streptomycin exerts a suppressive effect on the progress of tuberculous infection in man.

From the Research Department, National Jewish Hospital.

Read before the Section on Pathology and Physiology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 11, 1947.

This study was aided by the Jacques Labarrere fund for tuberculosis research.

Limitations to the intensity of the antibacterial activity and possibly to its duration have been demonstrated."[2] In a report of the results of a study of 100 treated patients it is noted that "Streptomycin is an antibacterial agent which possesses the unique ability to inhibit the growth of Mycobacterium tuberculosis in vivo, both experimentally and clinically. . . . In many instances streptomycin appears to suppress tuberculosis rather than to eradicate it, being apparently tuberculostatic rather than completely bactericidal in the concentrations which can be obtained in the tissues. . . . consistently encouraging results attendant on its use in a series of 100 cases in the past two years" is claimed[3] It is admitted, however, that a critical evaluation of the human study leaves much to be desired so far as definite results are concerned and that the standard accepted treatments of the past should not be forsaken. Aside from such general reports, there are individual case reports indicating a definite curative effect of streptomycin in human tuberculosis. One such, appearing as recently as March 1947 and reporting the successful treatment of 4 children (7 months to 3 years of age), who were given 1 Gm. daily for only one month, stated that this resulted "in defervescence in all 4, improvement in their general conditon and a regression of the appearance of the pulmonary lesions in the roentgenograms."[4] Such uncontrolled observations can only lead to a misconception of the actual value of streptomycin, if one exists, in man and the indiscriminate abuse of the treatment, without benefit.

In a previous publication we noted[1] that "streptomycin properly administered and in proper dosage is capable of retarding the development or growth of human tubercle bacilli, both in vitro and in vivo" in restricted laboratory experiments. "The concentration of streptomycin required to retard the growth of tubercle bacilli in vitro in good nutrient medium can only be attained in vivo for a brief period by any route of administration or amount of streptomycin that can be used even with the present high assay unit preparations. . . . There is no evidence available at present to indicate that streptomycin enters the important organs in appreciable amount for any significant time although it is present in the blood, or that it accumulates in these organs," or "that tubercle bacilli adsorb or absorb streptomycin or that it accumulates in these bacilli in vitro or in vivo."

Although their number is difficult to determine accurately, only few other reports on the organic distribution of streptomycin have appeared. Adcock and Hettig[5] studied the absorption, distribution and excretion of streptomycin in man. It was not absorbed appreciably when given orally or by inhalation, and a high concentration appeared in the feces after oral use. After parenteral administration, it was demonstrated in the blood serum in amounts roughly proportional to the dose, and appeared in the bile, the spinal fluid of subjects with meningitis, and in the pleural fluid in effusions. A postmortem study of its distribution, after it had been given by continuous subcutaneous infusion in excess of forty-eight hours extending to the time of death, revealed that it was present in high concentration in the kidney. Smaller amounts were found in the lung and in the heart muscle, while both the brain and the liver were virtually free from the substance. From 41 to 86 per cent of streptomycin was excreted in the urine within twelve hours after parenteral administration. More recently Nelson, Forgacs and Kucera[6] found no streptomycin in the organs of the mouse one hour after injecting 1,000 units. Using electronegatively charged trypan blue for anchoring the streptomycin, they were able to note it in determinable amounts in the blood, the liver and the spleen after twenty-five hours.

An earlier report by Zintel and co-workers[7] noted that after parenteral administration most of the streptomycin (29 to 89 per cent) is recovered from the urine in twenty-four hours, and little or no more is recovered after this. Streptomycin was found in most of the body fluids—blood, ascitic fluid, pleural fluid, aqueous humor, vitreous humor, amniotic fluid and bile. Small amounts were found in the spinal fluid, increasing in the presence of meningitis. Donovick and Rake,[8] using the mouse, recovered 61 per cent of the streptomycin from the urine with large doses and 45 per cent with smaller doses. Four hours after injection, 100 per cent of the drug was found.

That tubercle bacilli may acquire resistance to streptomycin, another feature of uncertain significance, is recorded. Its practical implication in regard to man is still unknown.[9] Streptomycin-resistant human type tubercle bacilli were found to be as virulent for white mice as streptomycin-sensitive strains. Infection produced in mice with streptomycin-resistant cultures were not suppressed by streptomycin treatment. Middlebrook and Yegian[10] noted that in all mycobacteria thus far tested resistance to streptomycin developed in vitro at a rapid rate and that it persisted for at least four months and appeared not to be paralleled by any diminution of virulence for guinea pigs.

THE IN VITRO EFFECTS OF STREPTOMYCIN

In earlier studies we showed that streptomycin was perceptibly less effective in retarding the growth of human tubercle bacilli on a good nutrient medium (egg yolk) than on a poor nutrient medium (broth agar) and that the amount of planting played a significant role in its effect on the bacilli. In a further study with liquid mediums, usually graded as poor nutrients for tubercle bacilli, rather interesting findings were recorded, which emphasizes the necessity of accurately defining the conditions under which retardation of growth occurs in tubercle bacilli or acid-fast bacilli influenced by streptomycin. In a preliminary titration test with the acid-fast bacillus "Day," it was found that while this organism would not grow in a dilution of less than 0.01 mg. per cubic centimeter of fine suspension planted in plain broth, the addition of 1 per cent dextrose to the medium altered this. In Wong Weinzirl's medium, a synthetic nonprotein medium without dextrose, growth occurred in 0.001 mg. per cubic centimeter plantings; and after the addition of 1 per cent dextrose, growth occurred in the 0.0001 mg. plantings, indicating the better growth-supporting nutrient qualities of the latter medium as compared with the former for acid-fast saprophytes as well as for tubercle bacilli. With the information at hand, the effect of streptomycin on standard plantings of acid-fast and tubercle bacilli was tested on a broth-unit basis with the results recorded in table 1. In addition, this table shows the effect of the addition of a non-nutrient, nontoxic, apparently inert soluble colloidal cellulose preparation.

* The tubes were all planted with 1 mg. per cubic centimeter of the acid-fast "Day" bacilli, and readings were made after two days at 37 C. Essentially the same results were noted with tubercle bacilli in similar tests.

The results recorded in table 1 indicate that the amount of streptomycin required to retard the growth of acid-fast bacilli can vary in liquid mediums from 1 unit for plain broth to 5 units for broth with dextrose, to 10 units for a synthetic nonprotein medium (Wong's) containing glycerin and dextrose, to over 100 units for the latter containing an inert non-nutrient soluble colloidal cellulose substance, in spite of no apparent change in the hydrogen ion concentration of the medium or loss of activity of the contained streptomycin as tested at the end of the experiment on a broth-unit basis.

* The addition of 1 per cent dextrose promoted growth with fine suspension planting up to concentrations of 10 to 50 units of streptomycin per cubic centimeter.

† S indicates 1 mg. per cubic centimeter fine suspension planting; L indicates planting of divided particles of bacillary mass directly from another culture; 0 means absence of growth; + means growth.

‡ The growth obtained from subcultures grown on 50 units streptomycin per cubic centimeter were transferred to streptomycin-containing mediums, and the direct results from these first transfers are indicated as 0T or +T.

§ No. 4068, H 160 and H 37/rv grew less vigorously on this medium than the other strains, although they grew equally well on good nutrient mediums.

The latitude of the arbitrary retardation produced in vitro by streptomycin is again evident if the tests are performed on a poor nutrient medium, such as glycerin agar, which requires relatively heavy plantings of the bacilli if evident growth is to be obtained. The growth on such a streptomycin-containing medium, the Wong glycerin agar medium, and the effect of the development of resistance to the streptomycin are presented in table 2.

It is noted from the results recorded in table 2 that tubercle bacilli are capable of growing directly on 10 to 1,000 units of streptomycin per cubic centimeter contained in a relatively poor nutrient solid medium, such as Wong's glycerin agar without dextrose, and that a first transplant from cultures containing 50 units of streptomycin invariably grew on 1,000 to over 10,000 units of streptomycin per cubic centimeter. It must be remembered that there is a striking difference between the growth of tubercle bacilli on nutrient liquid mediums and that on the same constituents incorporated in agar mediums, as pointed out by us years ago and verified recently by Dubos. The agar mediums require much heavier plants for successful growth. Another feature complicating interpretation and measurement of in vitro streptomycin retardations of tubercle bacilli and acid-fast bacilli is the fact that the micro-organisms will not grow on serum, plasma or blood directly unless these have been diluted with a nutrient medium or subjected to some other denaturing influence, such as heating or prior acid treatment and neutralization.[11] On the other hand, they will grow on organs, but the streptomycin unitage is disturbed. These findings with tissues and body fluids are presented in table 3.

The results recorded in table 3 indicate that at least 5 to 10 units of streptomycin is required to inhibit growth of acid-fast bacilli in ground organs (lung, liver, spleen and kidney), and, in spite of the fact that citrated plasma and blood sediment (red corpuscles) completely retard the growth of acid-fast bacilli (and tubercle bacilli), from 10 to 100 units of streptomycin is required to produce a retardant effect when these body fluids are diluted with Wong's liquid medium. The natural retardant action of the plasma is destroyed by heating for thirty minutes above 50 C.

Previously it was demonstrated that streptomycin can be found in the blood after injection but not in the heated organs. In an attempt to determine whether streptomycin could be demonstrated by unit assay in the fresh organs of exsanguinated guinea pigs, several animals weighing about 700 Gm. were given 125,000 units of streptomycin. One hour after injection of the streptomycin the organs were removed aseptically and used undiluted and diluted up to 1:5 with solution of sodium chloride for implantation of acid-fast saprophyte "Day," which was prepared in a fine suspension containing 1 mg. per cubic centimeter. Growth occurred on all the organs as such—lung, liver, spleen and kidney—and in the saline dilutions, suggesting an absence of demonstrable retarding concentrations of streptomycin in these organs following both intravenous and subcutaneous injection. Chemical assay methods, though tried by us, have proved completely unreliable for determining small amounts of streptomycin in the tissues.

THE EFFECT OF STREPTOMYCIN ON TUBERCULOSIS

Any consideration of the effect exerted by streptomycin on tuberculosis or on the tubercle bacillus in vivo resolves itself into the solution of three phases of the problem: whether streptomycin can kill tubercle bacilli in the host, whether it can completely retard the development of either the tubercle bacilli or the tuberculosis and, if not, whether it can partially retard them. The resolution of tuberculosis within a reasonable time is involved in the foregoing three phases, as is evident from any morphologic study with either dead or avirulent tubercle bacilli, and requires separate consideration.

† The concentration is given as units per cubic centimeter.

In order to note the action of streptomycin on virulent tubercle bacilli in vivo, animals were infected and treated at various periods for prolonged intervals, after which they were examined for viable tubercle bacilli and tuberculosis. In table 4 the condensed results of extensive studies of the various phases of this problem are presented.

It is noted from the data recorded in table 4 that prolonged streptomycin treatment retarded the tuberculosis but did not prevent death of the guinea pigs from tuberculosis. Positive cultures of virulent tubercle bacilli were obtained from all the important organs, regardless of whether the animal had received as little as 0.1 mg. of bacilli intravenously and had lived under treatment for as long as one hundred and eighty-one days. It was interesting to note also that if treatment was begun only one week after intravenous infection, after which the disease becomes established in the organs, the animal ultimately dies of generalized massive tuberculosis. An interesting feature of this experiment was that some of the guinea pigs taken off treatment after forty days survived almost as long as those treated continuously until death. Without going too far into interpretation, it appears that the streptomycin exerts its initial and potent effect at the time of infection or coincidentally with it, and that the establishment of immunity is a potent factor in the prevention of spread of the disease and delays death of the animal. This is further emphasized when the animal has been infected subcutaneously and treatment initiated with large doses of streptomycin after tuberculosis has become well established in the organs. In this case the streptomycin proves more toxic to these animals, which is evident from the fact that some of the animals succumb acutely with the initiation of treatment. Surviving this, they appear to reveal a retarding effect; but because of the marked variation in the results of infecting groups of such animals subcutaneously, no definite resolution of the disease is demonstrable.

TABLE 4.—*The Effect of Streptomycin Treatment on Guinea Pigs Infected Intravenously with 1 Mg. of Virulent Human Tubercle Bacilli (No. 4008)*

Interval After Infection When Animal Was Examined	Streptomycin Treatment	Results of Culture of Organs: Lung	Liver	Spleen	Kidney	Brain
1 day (animal killed)	Control—no treatment	3*	4	3	4	5
3 weeks (animal died)	Control—no treatment	2	3	3	3	2
77 days (animal died)†	12,000 units daily throughout	2	3	2	2	.
115 days (animal died)	Treatment begun 1 week after infection, 25,000 units daily until death	Massive tuberculous involvement of all important organs				
153 days (animal died)†	12,000 units daily throughout	3	4	3	4	3
181 days (animal killed)‡	12,000 units daily throughout	7	4	3	8	..

*The numeral indicates the number of weeks at the end of which positive cultures were obtained on glycerin-egg yolk medium.

Virulence tests of the strain recovered from these animals disclosed no change of virulence beyond that disclosed on the same strain when it was inoculated into these animals. Both in vitro and in vivo resistance tests were performed. The in vivo treatment experiments with streptomycin revealed an increased resistance to the effect of the streptomycin following passage through the streptomycin-treated animals.

These guinea pigs had been vaccinated with 1 mg. avirulent human tubercle bacilli one month prior to infection and the animal killed at one hundred and eighty-one days was the longest survivor.

In order to determine the effect of streptomycin on the viability of an avirulent strain of tubercle bacilli, which are naturally destroyed in the guinea pig in about one year after the intravenous injection of approximately 1 mg. of a fine suspension of bacilli, young guinea pigs were given intravenous injections of 1 mg.

TABLE 5.—*The Effect of Streptomycin Treatment on the Organic Distribution and the Viability of Avirulent Human Tubercle Bacilli Injected Intravenously*

Interval After Infection when Animal Was Examined *	Streptomycin Treatment	Results of Culture of Organs: Lung	Liver	Spleen	Kidney	Brain	Bone Marrow
1 month	No treatment	3†	3	3	4	0	3
100 days	No treatment	4	4	4	4	0	0
100 days	25,000 units daily throughout	5	4	4	4	5	6

* These animals weighed about 100 Gm. when given 1 mg. of viable avirulent human tubercle bacilli intravenously. They showed no apparent detrimental effect on their growth as compared with normal and streptomycin-treated controls.

† The numeral indicates the number of weeks that elapsed before a positive culture for tubercle bacilli resulted.

of an actively growing young culture of avirulent human tubercle bacilli, and some were treated with streptomycin while others were not treated. The organs were cultured, and the results are recorded in table 5.

The findings recorded in table 5 indicate definitely that intensive streptomycin treatment begun at the time of injection of viable avirulent human tubercle bacilli and continued for one hundred days exerts no appreciable effect on the viability of these avirulent tubercle bacilli in the various organs of the guinea pig even though the bacilli are present there in only relatively small numbers and naturally tend to be destroyed in these organs.

AN ATTEMPT TO DETERMINE THE MECHANISM BY WHICH TUBERCULOSIS IS RETARDED AFTER INJECTION OF STREPTOMYCIN

From all that has been determined with regard to the mechanism of the action of streptomycin in tuberculosis, it would appear that the general assumption is that it acts in the human being as it does in the test tube in vitro—as a bacteriostatic agent that retards the development of the tubercle bacilli or of tuberculosis or of both in the body. However, if it acts thus alone, there are in this explanation a number of voids which require further elucidation. It has not been demonstrated authentically that the streptomycin reaches the tubercle bacillus or the tubercle in active concentration or that it actually responds to all the requirements of true chemotherapy, since it should display either cidal action in some concentration or at some interval of time, or at least prove to be completely retardant of bacillary development in vivo under suitable in vivo set tests. Streptomycin does not do this. Even its retardant capacities were incomplete and fluctuated under the conditions of our experiment. It is not too much to expect that a drug which exerts such a profound effect on tuberculosis as is recorded clinically for man from some observations should yield equally clearcut abolition in the laboratory animal, in which the conditions of test can be controlled. At least it is well to determine the limitations of any new therapy. With this in mind, a few variations of tests have been tried in the hope of gaining a better insight into the action of streptomycin and, by comparison, elaborating on its chemotherapeutic action. We have been unable to prevent a lethal outcome of tuberculosis in animals by the use of streptomycin, although we have been able to delay that issue. Likewise, with regard to the tuberculin test, no effect of streptomycin treatment has been noted on the local intracutaneous tuberculin reaction, which indicates the presence of tuberculoallergic hypersensitiveness, either in immune or in nonimmune, infected guinea pigs. Some of the animals were immunized with 1 mg. of avirulent human tubercle bacilli, injected subcutaneously, and some were not, and all were infected with a virulent strain of human tubercle bacilli one to two months later and then treated continuously with 25,000 units of streptomycin subcutaneously daily throughout infection. The tuberculin tests were regularly recorded as showing 2 to 4 plus reactions to specific amounts of pure tuberculin, becoming more accentuated as time of infection and treatment increased.

In view of the known facts regarding streptomycin, its preparation, chemical structure and excretion, as well as its in vitro action as a retardant readily removed from the bacilli, it appeared advisable to study the occurrence of a delayed action in the animal and the possibility of the occurrence of some indirect effect on tuberculosis. Such studies have disclosed that even though streptomycin appears to leave the blood fairly rapidly after injection and cannot be discerned in the organs or in tuberculous tissues, guinea pigs treated for eighty-two to ninety-one days with 25,000 units of streptomycin daily and then infected intravenously with 1 mg. of virulent human tubercle bacilli in fine suspension one day after discontinuance of treatment, when streptomycin is not determinable in the blood, showed an increase of twenty-nine days in average duration of life as compared with the untreated controls, whose average was twenty-two days.

In another set of experiments in which treatment was instituted at the time of intravenous injection of 1 mg. of virulent human tubercle bacilli in fine suspension, a single subcutaneous injection of 25,000 units of streptomycin being given daily, a definite retardation of the tuberculosis occurred, comparable to that obtained by spacing injections so that four to six were made daily, totaling the same number of units. In the light of the data reported concerning excretion it appears that such an effect of a single daily injection of streptomycin could not be attributed entirely to the retardant effect of the drug on the bacilli. If again one is permitted to compare in vitro action, which obviously must be carefully interpreted, it has been found that growth of tubercle bacilli on liquid or good nutrient solid mediums is dependent on the amount of daily incubation at 37 C., so that, compared with controls continuously incubated at 37 C., cultures incubated for two thirds of the day are retarded only slightly, while those incubated only one third of the day, though growing perceptibly as compared with cultures kept continuously at room temperature (25 C.), show a decided retardation of growth as compared with the incubator (37 C.) cultures. According to prevalent observations, streptomycin remains in the blood for from four to twelve hours after a single injection.

Advantage is taken here of some observations made with a synthetic chemical agent of known composition, not an antibiotic. It is obtainable in chemically pure form, and acts as a retardant in vitro but fails completely in vivo in spite of the fact that it has a consistent retardant potency for acid-fast bacilli and tubercle bacilli in liquid nutrient mediums, regardless of composition of the medium, of 0.000,001 per cent for tubercle bacilli, while streptomycin is retardant only to 0.0001 per cent. It also is recoverable from the blood and the urine in amounts active against acid-fast bacilli after injection, but not from tissues except when added in vitro. The complete details concerning this compound will be reported later. When intravenously infected animals are treated intensely every two hours with almost as much of this compound as the daily amount of streptomycin used, one is surprised, considering the greater in vitro potency of this chemical compound as a retardant, to find that it does not retard the tuberculosis in the guinea pigs. On the contrary, not only do the treated animals reveal a generalized disease, surviving only as long as the controls, but the tuberculous spleens present a darker hue and an apparent increase in size over the controls. This is in contrast to the almost normal color of the spleen of the streptomycin-treated animal. To check these observations further, the effect of this compound and that of streptomycin were studied in normal mice and mice given intravenous injections of 5 mg. of heat-killed tubercle bacilli in fine suspension. The purpose was to study the effect of these drugs on the tubercle or the cellular tissue reaction produced by dead bacilli. At the end of two weeks the animals were examined, with the results recorded in table 6.

It is noted from the findings recorded in table 6 that streptomycin significantly retards the splenomegaly produced by heat-killed tubercle bacilli injected intravenously, in fine suspensions, into mice. The pure chemical substance that is retardant for acid-fast and tubercle bacilli, on the other hand, produces splenomegaly, not only in the normal mouse but also in the animal given dead tubercle bacilli intravenously.

Table 6.—*The Effect of Streptomycin Compared with That of a Chemical Retardant on the Splenomegaly Produced in Mice by Dead Tubercle Bacilli*

Type of Animals	Streptomycin Treatment	Splenic Weight *	Chemical Retardant Treatment	Splenic Weight *
Normal control......	....	190 mg.	....	202 mg.
Normal mice treated	20 mg. daily for 2 weeks †	190 mg.	20 mg. daily for 2 weeks	380 mg.
Mice given 5 mg. heat-killed tubercle bacilli intravenously	....	388 mg.	....	438 mg.
Mice given 5 mg. heat-killed tubercle bacilli intravenously and then treated	20 mg. daily for 2 weeks †	224 mg.	20 mg. daily for 2 weeks	678 mg.

* The average weight of the spleens is given.

† One and twenty-five hundredths grams of streptomycin equals 1,000,000 units.

SUMMARY AND CONCLUSIONS

In view of the evidence submitted here, streptomycin cannot be considered a cure for tuberculosis in man at present, since it did not destroy virulent human tubercle bacilli, nor did it completely retard their development in vivo.

Streptomycin apparently did not affect the viability of avirulent human tubercle bacilli in vivo.

In our experimental virulent infection, streptomycin did retard tuberculosis but could not prevent a lethal issue of the infection. From evidence available at present, there is no reason to suspect that streptomycin acts differently in man than in animals. None of the animals treated with streptomycin in our tests escaped the lethal issue after the development of virulent infection.

The intimate mechanism by which streptomycin acts in vivo is not fully understood. However, by way of comparison, a pure synthetic chemical substance which acts efficiently in vitro on the growth of tubercle bacilli and acid-fast bacilli and which, after injection in vivo, is demonstrated in the body fluids and the urine in active form was found not to be a retardant of experimental tuberculosis. The difference in action between the two materials in vivo is exemplified by the different splenic tissue reactions noted.

On the basis of evidence presented here and the unstable in vitro retarding unit value of streptomycin in simple mediums for acid-fast and tubercle bacilli, it appears desirable to obtain more controlled evidence before accepting streptomycin as more than incompletely retardant of tuberculosis in man.

The commercial availability of streptomycin should not interfere with additional controlled scientific investigations based on the knowledge gained through the study of this antibiotic.

ABSTRACT OF DISCUSSION

Dr. Emil Bogen, Los Angeles: Dr. Corper has again reported valuable experiments relating to the bacteriology of tuberculosis and the effect exerted by the tubercle bacillus on experimental animals. Many of the experiments are consistent with those made in our laboratory, which have been reported. In regard to others, we have had marked differences; I must differ particularly in consideration of the clinical interpretation which has been made. Streptomycin is a retardant rather than a bactericidal agent. The tubercle bacillus can be kept from growing, without being actually killed, over a wide range of concentrations of streptomycin. But this retarding action may be of considerable importance in saving lives. We have many guinea pigs surviving after treatment with streptomycin whereas the controls similarly inoculated died many months before. Guinea pigs treated with large doses of streptomycin show minimal lesions; in some cases we have not been able to find any lesions where the controls were riddled with the infection. Similarly, many patients now show complete healing of tuberculous lesions which had previously existed, whereas control patients with similar lesions still show persistence of such lesions. It is important that medicine have more experimental evidence, both in the test tube and in experimental animals, of the extent and the manner of effect of streptomycin and of the other substances which we hope will soon be developed for this purpose. But we must be happy that at last one substance has been found which, not only in the test tube and in experimental animals but also in the clinic, shows the value of experimental research in the chemotherapy of tuberculosis.

Dr. H. J. Corper, Denver: There is no discrepancy between some of these things. We notice drug houses have wisely put out streptomycin as an adjuvant and advise also continuing sanatorium treatment, and I think that is wise in view of what we know.

Clinical Notes, Suggestions and New Instruments

NEOSTIGMINE TOXICITY

Report of Fatality Following Diagnostic Test for Myasthenia Gravis

GEORGE G. MERRILL, M.D.
Baltimore, Maryland

Since the introduction of neostigmine as an aid in the diagnosis of myasthenia gravis,[1] it has been widely used for this purpose. Its injection in small doses is generally regarded as a relatively safe procedure. No reports of fatal reactions to its diagnostic use are found in the literature.

REPORT OF A CASE

A white man aged 39 consulted his physician because of generalized weakness for about two months. The history and physical examination were not remarkable except for some ptosis of the eyelids. As a therapeutic test for myasthenia gravis, 1 cc. of a 1:2,000 solution of neostigmine methylsulfate[2] was injected intramuscularly. No changes were noted for the first few minutes after injection. Then a generalized convulsive seizure occurred, five minutes after the administration of the neostigmine.

No fasciculations were noted at this time. Ten minutes after the injection, salivation and respiratory difficulty were noted, and the patient began to show signs of shock. Fifteen minutes after the injection, the pulse rate was found to be only 10 per minute, and the respiration was so depressed that artificial respiration was started. The shocklike state continued. Atropine sulfate, 0.4 mg. (gr. 1/150), and nikethamide were injected twenty-five minutes after the injection of the neostigmine

[2] Prepared by Hoffman-LaRoche, Inc

After this, the patient rallied somewhat, the salivation became less pronounced and the respiration and pulse improved. The pulse rate rose from 10 to 20 per minute. The injection of atropine was repeated in twenty minutes, but the patient gradually lapsed deeper into shock. The pulse became slower, the respiration more labored and the salivation and frothing more pronounced. Death occurred fifty minutes after the diagnostic injection of the 0.5 mg. of neostigmine.

At postmortem examination, the face was cyanotic. No other abnormalities were found on external examination. The body cavities were normal. The thymic remnant was somewhat larger than that usually seen. The heart was normal except for mild coronary arteriosclerosis. There was no coronary obstruction at any point, and no valvular or myocardial lesions. The lungs were hyperemic and extremely edematous, with frothy blood-tinged fluid streaming from the cut surfaces of all the lobes of both lungs. The bronchi and trachea were filled with frothy fluid. The spleen, liver and kidneys were decidedly hyperemic. The brain was normal except for considerable vascular engorgement and an increased amount of subarachnoid fluid. No other abnormalities were found. Microscopic examination confirmed the gross findings. In summary, the most striking finding at autopsy was the intense vascular engorgement occurring diffusely throughout the body, resulting in widespread capillary dilatation, edema and hyperemia of all the organs. These changes are of course characteristic of shock from any cause.

The materials used for injection were carefully investigated, to rule out any possibility of error in the strength of the solution or the technic of administration. The solution remaining in the vial used for the injection was assayed, by Mazur and Bodansky's[3] modification of Ammon's[4] method for assaying cholinesterase activity. The cholinesterase activity of this and other ampules from the same lot, tested against normal human plasma and compared with neostigmine samples of known strength, indicated that the solution used was in the proper concentration of 0.5 mg. per cubic centimeter.[5] This established the fact that only 0.5 mg. of neostigimine methylsulfate was actually injected.

COMMENT

In this case, the dramatic course of events following the injection of neostigmine suggests that the death was due to uncontrolled anticholinesterase activity. With the normal cholinesterase activity inhibited by the neostigmine, the action of acetylcholine was unopposed. A fatal vagotonic shock resulted. The microscopic pathologic changes agreed closely with those described by Altschul and Laskin[6] in their animals dying of overdosage of acetylcholine.

This profound physiologic disturbance from such a small amount of neostigmine is difficult to explain. Altschul[7] found a considerable variation in individual susceptibility to this drug in experimental animals. Possibly similar variations in susceptibility exist among the human population. Another factor is the convulsion that ushered in the untoward symptoms in this case. It is possible that the excessive neuromuscular activity occurring in a convulsive seizure produced an overwhelming amount of acetylcholine. Since cholinesterase normally destroys acetylcholine and since the cholinesterase in this case was inhibited by the neostigmine, the body was poorly prepared to cope with any increased production of acetylcholine. The acetylcholine could then accumulate in the body until it reached a concentration sufficient to induce shock. This case has certain similarities to the nearly fatal case described by Goodman and Bruckner,[8] in which muscular exercise apparently increased the acetylcholine concentration to a degree that was dangerous in proportion to the neostigmine-inhibited cholinesterase. The excessive neuromuscular activity of a convulsive seizure would doubtless liberate more acetylcholine than the walking in Goodman and Bruckner's case. The sudden onset of a convulsive seizure in a man previously free of such phenomena is of course unexplained.

Whatever the exact mechanism of the untoward result of administration of neostigmine in this case, the inescapable conclusion is, as Goodman and Gilman[9] pointed out, that the use of neostigmine demands caution and respect.

STREPTOMYCIN AND SULFADIAZINE (COMBINED) IN CHRONIC BRUCELLOSIS

HAROLD J. HARRIS, M.D.
New York
and
PAGE C. JETT, M.D.
Prince Frederick, Md.

The following report is made at this time because of the favorable effect of adequate dosage of streptomycin and sulfadiazine given concomitantly to a patient suffering from chronic brucellosis due to Brucella suis infection and because there is little in the current literature on the combined use of streptomycin and sulfadiazine in Brucella infection. Also it seems of value to call attention again to the fact that the hog variety of Brucella (Br. suis) is not confined to the hog-raising regions of the United States.

Sulfadiazine or other sulfonamide compounds have not proved effective in an impressive percentage of cases of chronic brucellosis, although there is much evidence that they may be effective in the acute infection. Even in the acute illness relapse frequently follows discontinuance of the sulfonamide compound.

Streptomycin is not generally accepted as effective against Brucella in vivo, perhaps because of the inconclusive early reports[1] of its failure to bring about definitive results. It is possible that these early reports were based on inadequate dosage or on insufficiently prolonged treatment, or both, as mentioned in the reports themselves. Also it is probable that there is additive effect when streptomycin is administered in conjunction with sulfadiazine, and perhaps with other sulfonamide compounds.

The apparently successful treatment of 2 patients with acute brucellosis by combined use of sulfadiazine and streptomycin was reported by Pulaski and Amspacher.[2] In a later personal communication they[3] reported similar results in 3 of 4 additional cases. The fourth patient recovered but in a manner which suggested spontaneous remission, they thought. Eisele and McCullough[4] reported successful treatment of an acutely ill patient.

In July 1947 the first opportunity was presented to evaluate the method in a chronic Brucella infection.

REPORT OF CASE

A farmer aged 42 years living in southern Maryland complained of fatigue, sweating, epigastric discomfort and severe headache in September 1946. Symptoms had recurred at irregular intervals for several weeks, but headache had been rather constant, coming on at about 9 or 10 a. m. and persisting until about 4 p. m. daily. The temperature ranged from 99 to 100.8 F. Other likely causes for his illness having been excluded, brucellosis was strongly suspected. Blood agglutination reaction with Brucella was positive in a dilution of 1:1,280 on September 28. Other laboratory study was negative or noninformative, as was physical examination.

He was referred by one of us (P. C. J.) to the other (H. J. H.) on October 7 for confirmation of diagnosis and for advice as to treatment. He was a well developed, healthy-looking man and did not appear really ill. In fact, he stated only that he was "a little damp," and mentioned briefly that he had "neuralgic headaches and stomach upsets." It required questioning to bring out that fatigue had been great and that he had had a stiff elbow for a month or two in February, with no swelling, redness or local heat. Also he recalled that he had been stiff all summer after heavy lifting, and that sexual desire had lessened.

He had been born in southern Maryland and had always lived on a farm in that region. There had been practically no illnesses except for "a touch of pneumonia three or four years ago." His cattle had never aborted or been suspected of having Bang's disease. The small herd of 12 or 13 cows had recently showed negative blood agglutination reactions. However, abortion had occurred among his swine; 1 sow had lost two successive litters in March and June, each time about half way through the gestation period. Interestingly the hogs had been in the same pasture with the cows in which no apparent infection developed. Raw milk was used from these cows.

Physical examination on October 7 revealed no significant abnormality. He was 71 inches (180.3 cm.) tall and weighed 181 pounds (82.1 Kg.). The spleen was not palpable. His pulse rate was 88, his temperature 100 F. and his blood pressure 120 systolic and 62 diastolic. Hemoglobin was 90 per cent (14.6 Gm.) (determined by the Dare method); the red blood cell count was 4,350,000, white blood cell count 5,500, with 46 per cent polymorphonuclear neutrophils, 2 per cent eosinophils, 51 per cent lymphocytes and 1 per cent basophils. The sedimentation rate was 45 mm. per hour (Westergren method). Microscopic blood agglutination reaction with Br. abortus was complete in 1:40 and 1:80 dilutions (tests in higher dilutions were not carried out by this method). Macroscopic tube agglutination reaction was positive in a 1:640 dilution. Opsonocytophagic reaction showed pronounced phagocytosis in 0 cells, moderate in 0 cells, slight in 17 cells and none in 8 cells, a Foshay numerical index of 17. No cutaneous test had been performed to date, but was then done, 0.1 cc. of "brucellergen" 1:12,000 dilution intradermally in one arm and 0.1 cc. of heat-killed Br. abortus organisms in the other arm. The "brucellergen" reaction was negative at the end of twenty-four and forty-eight hours and subsequently. Reaction to heat-killed Br. abortus organisms was positive.

Blood culture yielded Br. suis. Studies of susceptibility to streptomycin showed that the organism was susceptible to 1 unit of streptomycin; i. e., it was five times as resistant as standard.

Intramuscular administration of Br. abortus vaccine in any dilution necessary to avoid more than slight local, focal or systemic reaction was advised as a preliminary method of treatment, with the reservation that failure of complete recovery might occur. In that event it was suggested that streptomycin and sulfadiazine should then be administered, simultaneously, in adequate dosage and over a period of about twenty-one days. Vaccine was administered in a dilution of 1:100, intramuscularly, beginning with 0.1 cc. on October 22 and ending on November 8. Increments used were 0.1 to 0.4 cc., at intervals of three to six days, instead of the usual smaller increments and intervals of four to seven days. There were no apparent reactions to the five doses of vaccine given except for slight additonal elevation of temperature following the first two doses and lowering of fever curve following each of the latter three doses. After this regimen the patient resumed his farm work, improved but not fully recovered, still with a temperature ranging from 99.8 to 100.8 F. each afternoon. On one occasion in November the spleen was felt.

In July 1947, about one year after the onset of symptoms referable to brucellosis, because of continued low grade fever, fatigue and muscle and articular pains, the original plan for use of streptomycin parenterally and sulfadiazine orally was put into effect. Treatment was begun with 4 Gm. of streptomycin and 6 Gm. of sulfadiazine daily. After five days of this dosage of streptomycin it was reduced to 2 Gm. daily for three days and then to 1 Gm. daily for the remainder of the period of nineteen days. A total of 44 Gm. of streptomycin was used. The dosage of sulfadiazine was sufficient to keep the blood level between 5.9 and 6.3 mg. The amount of streptomycin used was less than planned because of the improvement which was evident at the end of forty-eight hours, at which time the patient was entirely free of fever and all symptoms.

There were no noticeable toxic effects from this dosage of streptomycin. It had been planned to discontinue its use at once if symptoms referable to involvement of the eighth nerve became evident.

The patient has remained afebrile and symptomless for four months, except for an unrelated sinus infection in November 1947. Blood culture for Brucella was negative at that time.

SUMMARY

So far as is known, this is the first reported case of chronic brucellosis successfully treated with streptomycin and sulfadiazine, concomitantly. The following points have been brought out: A man aged 42 years suffering from chronic brucellosis due to Br. suis showed few physical changes. There was low grade fever, slight leukopenia with relative lymphocytosis, blood agglutination reaction with Brucella in high titer, slight phagocytic activity of the white cells, positive intradermal reaction to Br. abortus killed organisms but negative intradermal reaction to "brucellergen," and positive blood culture. The increased erythrocyte sedimentation rate was of interest because it is not usual in uncomplicated Brucella infections. Also unusual was the moderate degree of intradermal reaction to killed Br. abortus organisms in a farmer whose exposure presumably had been by direct contact with infected animals. Particularly significant but not uncommon was the lack of cutaneous sensitivity to "brucellergen" but characteristic reaction to a more sensitive antigen, heat-killed Br. abortus organisms. Also of interest was the fact that the organism recovered was of the hog variety although originating in the Eastern United States.

The phagocytic reaction in this patient would be classified as "negative" by those who believe that phagocytic indexes as high as 30 may occur in blood of "normal" persons, although in fact low degrees of phagocytic activity against Brucella are a common finding regardless of the severity of infection. Had "brucellergen" been the only skin-testing antigen used, as is often the case, a negative reaction would have resulted. Had specific agglutinins not been present in high titer, the diagnosis then would have rested on blood culture alone—a procedure for which few laboratories have proper facilities or trained personnel. In this chronic illness there was the unusual good fortune to have adequate diagnostic data.

Whereas relapse still may occur, the complete freedom from any evidence of Brucella infection for a period of four months after specific treatment, following one year of chronic illness, seems sufficiently significant to justify further attempts at evaluation of this combined form of chemotherapy in acute or chronic brucellosis. Prolonged dosage of both drugs seems indicated, with sufficiently high initial dose to avoid the likelihood of resistance to streptomycin. Due regard to possible toxic effects obviously is necessary.

Painless Coronary Infarction.—Clinical statistics are presented which indicate that all suitable cases of angina pectoris can be relieved of their crushing precordial and arm pain by properly executed neurosurgical procedures. These patients do not lose the danger signal which warns against over-exertion, but it is no longer agonizing pain. In skilled hands surgical intervention is no more dangerous than any of the other common major operations in this age group. Once relieved of their pain, these patients are able to live happier and more active lives, free from fear of ever-recurring attacks and less conscious of impending death. They are no longer threatened with addiction to morphine, lack of sleep, and worry, which so often are factors accelerating termination of life by coronary occlusion. If fatal coronary infarction takes place, it is usually painless.—White, James C., and Bland, Edward F.: *Medicine*, February 1948.

Council on Pharmacy and Chemistry

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., *Secretary.*

Report to the Council on Pharmacy and Chemistry by the Committee on Drug Addiction and Narcotics of the National Research Council, prepared for the committee by Dr. Nathan B. Eddy, Secretary.

METOPON HYDROCHLORIDE

(Methyldihydromorphinone Hydrochloride)

Metopon (or methyldihydromorphinone) represents a new type of nuclear substitution in the morphine series for which the method of preparation was discovered by Small in 1936. The essential difference in metopon is the presence of a methyl group attached to the hydroaromatic ring of morphine. It also differs from morphine by the presence of a ketone in place of the alcoholic hydroxyl and by removal of one double bond by hydrogenation. Pharmacologic examination and clinical trial demonstrated that these chemical changes effected quantitative dissociation of components of the morphine picture - increase in analgesic action, decrease in euphoric, sedative, emetic and intestinal effects. Tolerance to and dependence on metopon developed more slowly and tolerance disappeared more rapidly than with morphine. Substituted for morphine in cases of addiction, it did not fully satisfy the craving or completely suppress abstinence phenomena. The minimal analgesic dose, the incidence of adequate relief and of side actions, and the duration of action were the same for oral and hypodermic doses administered for the relief of clinical pain.

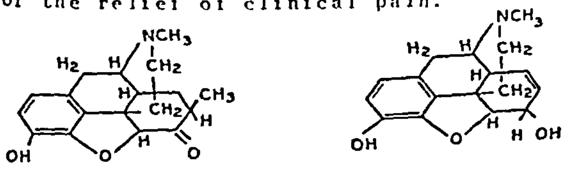

Fig. 1.—Structural formulas of metopon (methyldihydromorphinone) on the left and morphine on the right.

In review of the evidence on metopon in 1946 the Drug Addiction Committee of the National Research Council judged that in comparison with morphine the differences already outlined were clearly demonstrated. The Committee believed that these differences indicated the possibility of advantageous employment of the drug by the oral route for the control of chronic pain such as that in cancer. To test this possibility they recommended limited commercial production and distribution of metopon under a plan of supervision which would channel the drug to cancer patients only and which would seek to gather reports on its effectiveness for such cases in general practice. The plan of supervision has been published,* and this report reviews the first six months of its operation from May 15 to Nov. 15, 1947.

Figure 2 presents a graph of the amount of metopon distributed on original orders and reorders. Two thousand, eight hundred and twenty-nine physicians have ordered the drug for 4,288 patients. As of November 15, 20 per cent of all physicians who had ordered metopon had reordered and 33 per cent of these had reordered more than once. Both these figures are lower than the true extent to which physicians are reordering, since the figure for physicians ordering initially is also compiled to November 15 and obviously some proportion on that date had not yet received the drug and a larger number had used it too short a time to reorder. One hundred and six reorders were received in the three week period November 15 to December 5; fifty-five were from physicians reordering for the first time. In other words, as of December 5, 21.8 per cent of the physicians who had ordered metopon by November 15 had reordered at least once, which certainly represents only a partial correction for the time factor. Another estimate of the continuing use of the drug is derived from physicians' reports. Three hundred and forty, or 12 per cent, of physicians have reported on or signified their intent to use metopon for 461 additional patients, approximately 11 per cent of the number for whom the drug was ordered originally.

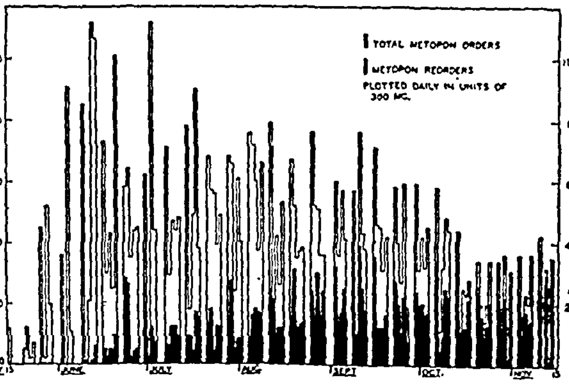

Fig. 2.—Amount of metopon distributed on orders and reorders.

Only eighteen orders for metopon have been rejected because the case for which it was intended was not one of cancer, cancer being interpreted in a broad sense to include all types of malignant tumor. A few physicians have asked or have tried to use the drug on other patients in addition to 1 or more patients with cancer, but to the best of our knowledge the drug has been sought for only 43 noncancerous patients, only 1 per cent of the total. Only ten other original orders have been rejected either because a satisfactory statement in regard to the diagnosis or the attending physician has not been supplied or because the narcotic order has been improperly executed. In each instance an effort was made to get the information or to have the error corrected before the order was rejected.

One of the requirements of the Committee's program of supervision is that a reorder shall be filled only after the physician has reported on the use of metopon. One hundred and one physicians have overlooked this requirement, but most have responded promptly when reminded of it. Only eleven reorders have been rejected because we were unable to get a report. Some reorders are received with which the physician states that he intends the drug for a new patient. Such reorders are approved whether or not the physician has reported, though he is asked again under these circumstances for a report on each case and usually responds promptly.

Practically all the cancer patients for whom metopon has been sought were in the terminal stage of recurrence and/or metastasis. Two hundred and twenty-seven, or 5 per cent, are known to have died before the drug could be received. Physicians have reported nonuse of the drug after ordering in 131 other cases, principally because other medical care was obtained, the patient moved from the locality or there was a recession in the pain of the disease. Correcting the total number for deaths, nonuse and noncancerous cases, metopon is presumed to have been used for 3,887 patients. This figure is undoubtedly too high, because deaths and nonuse certainly were not reported completely. Physicians have reported on the use of the drug in 1,841 cases. Some effort is required to attain this response, since four hundred and twenty-six reminder letters have been written and several hundred more are being written now. Reports from two hundred and ninety physicians have been received through these reminders. Tables 1 and 2 present a general summary of all reports.

---

*J.A.M.A. 134:291-292, 1947; J. Am. Pharm. A. (Pract. Pharm. Ed.) 8:430-433, 1947. Also in most of the state medical association journals, June to October, 1947.

Table 1.—*General Summary of Reports on the Use of Metopon**

Reasons given for trial of metopon:		
For better pain relief	946	
To avoid hypodermic administration	389	
Nausea and/or vomiting with morphine or other narcotic	277	
Mental dulness with morphine or other narcotic	87	
To avoid addiction	63	
Trial, no specific reason given	274	
Reports judged to indicate fair trial	1,341	
Reports unsatisfactory for assessment of analgesic effect	500	
Pain relief: Complete	477	(80 %)
Fair	598	
Poor	187	
None	79	
Mental condition: Clear	1,142	(75%)
Dull	286	
"Dopey"	75	
Confused	29	
Sleep promoted or permitted by relief of pain	445	(27 %)
Sleep not promoted	1,192	

*In each table figures represent cases in which the item is reported. Totals for pain relief, mental condition and sleep are uneven because of inadequacy of data on some reports.

Among the reasons given for trial of metopon, "for better pain relief" usually means that tolerance to other narcotics has already developed, since it is always specifically stated for these cases that previous medication was inadequate. Also other narcotics (morphine, codeine, dihydromorphinine, "pantopon" the total alkaloids of opium as soluble hydrochlorides or meperidine, in various sequences or combinations, frequently all of them) have been administered for six months or more in 39 per cent and for two months or more in 72 per cent of all cases for which information on this point is available. There was no narcotic medication prior to metopon in only 74 cases.

Table 2.—*Side Reactions with Metopon*

None	1,502	Disturbing dreams	6
Nausea	87	Itching	4
Restlessness	23	Anorexia	3
Headache	14	Urticaria	2
Perspiration	12	Tinnitus	2
Dryness or burning in throat and stomach	10	Allergic reaction	1
		Edema of face	1
Dizziness	9	Palpitation	1
Euphoria	7	Hiccup	1
Burning of skin and/or hot flushes	6	*Difficulty in urination*	1
Nausea, previously reported (277), persisting after metopon			27
Signs of physical and psychic dependence for which metopon was discontinued after brief trial			104
Signs of physical dependence disappearing under continued administration of metopon			45

With respect to other reasons for trial of metopon, the figure for "nausea and or vomiting with morphine or other narcotic" is surely too low. Unfortunately, a specific query on this point was not on the protocol sent to physicians to report results. Also there are included under "trial, no specific reason given" all cases in which it is said that the patients were intolerant to morphine or that they wished to avoid side effects, but for whom emetic action is not directly stated.

In table 1 effects are shown without regard to the dose employed. All reports which show dose and effect, are included in the tally unless attending conditions are described which obviously vitiate the result. These include attempted administration to patients close to death, attempted administration where nothing given by mouth was being retained and cases in which one or at most only a few doses of metopon were given because of the patient's demand for return to hypodermic medication with or without the appearance of signs of physical dependence, the physician admitting that addiction to morphine or other narcotic was the reason for failure. There were 104 cases in which administration of metopon was shortly discontinued because of its failure to satisfy an existing addiction and its inability to prevent the occurrence of abstinence phenomena. Pain relief was admitted to be fair or better in only 25 per cent of this group. On the other hand, 45 cases have been reported in which in spite of the appearance of abstinence phenomena administration of metopon was continued. The withdrawal signs disappeared gradually, and the net result was excellent. It is probable that some of the symptoms listed in table 2 as side reactions were in fact abstinence phenomena. This is especially probable for the symptom of nausea, which frequently did not appear until after several doses of metopon had been given or at about the time after the last dose of the previous narcotic at which one would expect to see the first signs of withdrawal. It is noteworthy that nausea after metopon therapy was reported in only 27 of the 277 patients known to have been nauseated by previous medicaments.

Restlessness as a side effect has been reported in 23 instances. This is in addition to the group previously mentioned in which mental agitation and anxiety as signs of psychic dependence caused the physician to discontinue administration of metopon. Euphoria was noted only in 7 instances. In 73 per cent of the cases metopon was said not to promote sleep. Even when the report indicates that sleep followed its administration, the note is often added that this is probably *only secondary* to the relief of pain. The retention of mental clarity, the absence of euphoria and general sedation were sometimes considered disadvantageous. Twelve times, although in most instances pain relief was adequate, metopon was discontinued *because* of lack of sedative effects. Sometimes the physician found it desirable to give a barbiturate or a small dose of another narcotic at bedtime.

The recommended starting dose of metopon *for oral administration is not less than 6 mg.* This has been clearly stated in all literature on the use of the drug under this program. Cross tolerance among the opiates has also been referred to, and the possibility of cross tolerance to metopon after prolonged *administration of morphine* and related substances. Such cross tolerance would be expected to require upward adjustment of dosage. There*fore*, to facilitate close adjustment of dose to need under varying circumstances the dosage form *originally* adopted is a capsule containing 3 mg. of metopon hydrochloride and the dose *is* "two or three capsules to be repeated only on recurrence of pain." It is surprising that physicians have commonly disregarded all dosage recommendations, *directing that the capsules be taken singly* at least initially. In 28 per cent of all trials the amount of drug per dose has not *been* increased beyond 3 mg. In 45 per cent of trials administration has started at or has shortly been increased to 6 mg. In 25 per cent of trials the dose has been increased to 9 mg., but in only 2 per cent has it been increased beyond that level.

Reference has already been made to the extent of narcotic administration prior to trial of metopon. This breaks down readily into three categories: (1) no previous narcotic, 74 cases; (2) narcotic administration for six weeks or less, a period in which relatively little tolerance and dependence will have developed as a rule, 339 cases, and (3) narcotic administration for two months or more, when some tolerance and dependence will almost certainly have developed, 1,200 cases.

Table 3.—*Influence of Previous Narcotic Administration on the Result Obtained with Metopon, 6 Mg. per Dose*

	No Previous Narcotic	Narcotic Administration 6 Wk. or Less	Narcotic Administration 2 Mo. or More
Number of cases	35	152	492
Pain relief:			
Complete	19(54%)	69 (45%)	135 (27%)
Fair	13(37%)	37 (24%)	199 (40%)
Poor	1	30	105
None	2	16	53
Incidence of nausea	0	5 (1:30)	20 (1:24.5)

Using only the results of 6 mg. doses of metopon, table 3 summarizes the influence of the previous medication. Quite definitely the incidence of adequate relief, fair or better, and particularly of complete relief is less the more previous narcotic medication the patient had received. It should be pointed out, however, that there is probably a relation between the duration and severity of the disease, at least the severity of pain as a symptom of the disease, and the extent of previous medication, so that cross tolerance may not entirely account for the difference shown.

The incidence of nausea as a possible side effect increases from none (where there had been no narcotic given prior to metopon) to about once in twenty-four times where there had been the greatest amount of previous medication. This supports the suggestion already made that some of the symptoms listed as side effects were really withdrawal symptoms. It is also possible in line with the statement of the previous paragraph that at least part of the nausea was incidental, related to the advanced stage of the disease and widespread metastases, and not associated with the medicament.

Two hundred and fifty-eight physicians have reported more than once on the effect of metopon in the same patient. In 164 cases the effect was the same at intervals of one to twenty weeks without change in dose; in 24 cases the effect was reported as increased in the second report, and in 70 cases it was diminished. In other words, there is no evidence of tolerance to metopon in 127, or 50 per cent, of cases in which administration is known to have continued for at least four weeks and none in 37, or 14 per cent, of cases of continued administration for eight weeks or more.

In some reports duration of effect is specifically stated as five to ten hours. In many more it is indicated only indirectly by the statement that only two or three doses per day were taken. In a few instances the effect has been reported as brief, one hour or less. In another small group the patients have complained of slowness of onset of pain relief.

In conclusion, this six months of experience with metopon in general practice has confirmed the earlier results of controlled clinical trials. It is an adequate analgesic for severe chronic pain when administered orally, and such administration is attended by a high degree of mental clarity and few side reactions. The satisfactoriness of its use is improved if its administration is begun as soon as the need for a potent analgesic arises, before the administration of morphine and other related substances has led to diminished effectiveness through the development of tolerance. The committee believes that the production of metopon should be continued, but that it should be recommended and made available only for oral administration for chronic pain. On May 15, 1948 the present program of supervision of the distribution of metopon by the Committee on Drug Addiction of the National Research Council will be terminated. Thereafter the drug may be obtained through regular channels in the same way as morphine and related substances. It must be remembered, however, that metopon is a morphine derivative and, like the latter, subject to narcotic regulations.

The drug will continue to be available only in capsule form for oral administration. Since it is important to hold narcotic administration to a minimum, to facilitate this and to permit adjustment of dose to the need of a particular case each capsule will contain 3 mg. of metopon hydrochloride. The minimal effective analgesic dose in nontolerant persons is 6 mg. Therefore, the dose is two capsules for persons who have not taken morphine and related substances previously, and it may be three or more capsules for persons already tolerant to morphine and the like. Institution of treatment with metopon hydrochloride in the latter group should be accompanied by rapid reduction rather than abrupt discontinuance of the previous medication.

The Committee on Drug Addiction and Narcotics of the National Research Council through its secretary (Nathan B. Eddy, National Institute of Health, Bethesda 14, Md.) will be glad to continue its correspondence with physicians in regard to their experience with metopon hydrochloride and to advise them on the use of the drug.

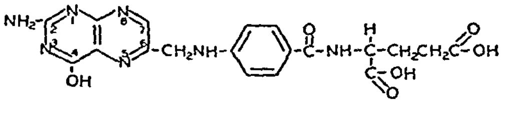
NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

FOLIC ACID.--Pteroylglutamic acid.--N 4 (2-amino-4-hydroxy-6-pteridyl)-methyl -amino -benzoyl glutamic acid.--$C_{19}H_{19}O_6N_7$.--M.W. 441.4.

The structural formula of folic acid may be represented as follows:



Actions and Uses.--(See New and Nonofficial Remedies 1947, p 517).

Dosage.--(See New and Nonofficial Remedies 1947, p 517).

Tests and Standards

Folic acid occurs as a yellowish-orange crystalline powder.

It is insoluble in ethanol, benzene, chloroform, ether and water, although very slightly soluble in hot water.

Dissolve about 5 mg. of folic acid in 5 cc. of glacial acetic acid. Add 1 cc. of 30 per cent hydrogen peroxide and allow to stand for 4 hours: the solution is completely decolorized.

Dry about 0.1 Gm. of folic acid, accurately weighed, in vacuum over phosphorus pentoxide at room temperature in the dark for 120 hours: the loss in weight does not exceed 10 per cent.

Char over a low flame 0.2 Gm. of folic acid, accurately weighed. Cool, then moisten the charred material with 1 cc. sulfuric acid. Cautiously ignite until ashing is complete: the residue does not exceed 0.5 per cent on the anhydrous basis.

Treat the residue from the sulfated ash with 2-3 drops of hydrochloric acid and evaporate to dryness on the steam bath. Add 10 cc. of 2 per cent hydrochloric acid and heat for 5 minutes on the steam bath. Filter through paper into a Nessler tube. Repeat the acid treatment of the residue with 10 cc. more of 2 per cent hydrochloric acid. Dilute to 25 cc., and add 10 cc. of hydrogen sulfide T.S. Allow to stand in the dark for 10 minutes: no more turbidity develops than corresponds to 50 parts per million of lead (U.S.P. XIII).

Place about 100 mg. of para-aminobenzoic acid, accurately weighed, in a 100 cc. volumetric flask, add 50 per cent ethanol to dissolve the solid, and dilute to the mark with 50 per cent ethanol. Transfer 1 cc. of the p-aminobenzoic acid solution to a 250 cc. volumetric flask, add 200 cc. of water, 25 cc. of 5 N hydrochloric acid, 2.5 cc. of a 0.5 per cent gelatin solution (0.5 Gm. gelatin and 0.1 Gm. benzoic acid in 100 cc. water), and finally dilute to the mark with water. Prepare a standard curve, using sufficient solution to give a range of final concentrations of 4 to 20 micrograms, developing the color as described for folic acid as follows:

Weigh, accurately, about 0.1 Gm. of folic acid and transfer to a 100 cc. volumetric flask. Dissolve the folic acid and dilute to the mark with 0.1 N sodium hydroxide. Transfer 1 cc. of the solution to a 100 cc. volumetric flask and add 80 cc. of water, 10 cc. of 5 N hydrochloric acid, 1 cc. of 0.5 per cent gelatin solution, and water to the mark. Withdraw 2 cc. of the mixed solution before reduction and determine the free amine as directed for p-aminobenzoic acid. Transfer the rest of the solution to a 250 cc. Erlenmeyer flask and add 0.5 Gm. of zinc dust. Allow the mixture to stand 10 minutes with intermittent shaking. Filter to free the reduced solution from zinc dust. Pipette 2 cc. of the reduced solution to a 10 cc. volumetric flask. Dilute to 6.6 cc. with water, add 0.4 cc. of 5 N hydrochloric acid and 1 cc. of 0.1 per cent sodium nitrite solution. Mix and let stand 3 minutes and add 1 cc. of 0.5 per cent ammonium sulfamate solution. Mix and let stand 2 minutes, add 1 cc. of a 0.1 per cent N-(1-naphthyl)-ethylenediamine dihydrochloride solution. Mix and allow to stand 5 minutes. Read the light absorption of the solution with a spectrophotometer at 5500 Å, using water as a blank. Determine the concentration of the solution in terms of p-aminobenzoic acid from the standard curve.

Calculate the total folic acid present from the following equation:

$$\text{micrograms as p-aminobenzoic acid} - \text{micrograms free amine} \times \frac{441.4}{137.06} = \text{folic acid found}$$

The folic acid content is not less than 90 per cent on the anhydrous basis.

Folic Acid Tablets

Weigh, accurately, 25 tablets of folic acid. Grind to a fine powder in a mortar and then weigh out an amount equivalent to 100 mg. of folic acid. Transfer the weighed portion to a 100 cc. volumetric flask and dilute to 100 cc. with 0.1 N sodium hydroxide. Centrifuge and transfer 1 cc. to a 100 cc. volumetric flask, and continue the assay for folic acid as described in the preceding paragraphs, beginning with the sentence "Transfer 1 cc. of the solution to a 100 cc. volumetric flask . . .". The folic acid content of the tablets is not less than 90 nor more than 115 per cent.

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Folic Acid: 5 mg.

KREMERS-URBAN CO., MILWAUKEE

Tablets Folic Acid: 5 mg.

LEDERLE LABORATORIES DIVISION, PEARL RIVER, N. Y.

Elixir Folvite: 5 mg. per 4 cc., 125 cc. bottles.

Solution Sodium Folvite: 15 mg. per cc. ampuls.

2,3-DIMERCAPTOPROPANOL IN OIL.—BAL in Oil-H. W. & D.—A solution of 2,3-dimercaptopropanol 10 per cent in peanut oil, containing benzyl benzoate 20 per cent.—$C_3H_8OS_2$—M. W. 124.21

Actions and Uses.—2,3-Dimercaptopropanol in oil is indicated in the treatment of arsenic, gold and mercury poisoning.

2,3-Dimercaptopropanol is particularly useful in the treatment of hemorrhagic encephalitis due to massive arsenotherapy, arsenical or gold dermatitis and possibly postarsenical jaundice but not homologous serum jaundice following parenteral therapy. It is useful as an adjunct in the treatment of agranulocytosis due to arsenic, but other measures, principally massive doses of penicillin, must also be employed.

While 2,3-Dimercaptopropanol in oil is indicated in the treatment of mercury poisoning, it must be remembered that mercury causes rapid and extensive tissue damage, particularly to the kidneys, which cannot be corrected by the administration of this drug. The use of 2,3-Dimercaptopropanol in oil in the treatment of mercury poisoning is still in the experimental stage, and definite recommendations cannot be made.

The toxicity of the drug appears to be less in patients suffering from arsenic, gold or mercury poisoning, but doses of 300 mg. per kilogram of body weight may produce nausea, vomiting and headache; a burning sensation of the lips, mouth, throat and eyes; generalized muscular aches with burning and tingling of the extremities, and a sense of constriction in the chest. The symptoms usually subside in thirty to ninety minutes.

Dosage.—In the treatment of arsenic or gold poisoning, 3 mg. per kilogram of 2,3-Dimercaptopropanol (as a 10 per cent solution in oil) should be administered by intramuscular injection as follows: every four hours for the first two days; four injections on the third day, and injections twice daily thereafter for ten days or until complete recovery. In milder cases the dose may be reduced to 2.5 mg. per kilogram.

HYNSON, WESTCOTT & DUNNING, INC., BALTIMORE

Solution Bal in Oil: 4½ cc. ampuls. 2,3-Dimercaptopropanol 10 per cent and benzyl benzoate 20 per cent in peanut oil.

Council on Physical Medicine

ABSTRACT OF MINUTES OF MEETING OF THE COUNCIL ON PHYSICAL MEDICINE

Dec. 12 and 13, 1947

The Council on Physical Medicine held its regular annual meeting on Dec. 12 and 13, 1947. Those present were Drs. Morris A. Bowie, Anthony C. Cipollaro, W. W. Coblentz, John S. Coulter, W. E. Garrey, W. E. Grove, Frank H. Krusen, Frank R. Ober, George Morris Piersol and Derrick Vail. Dr. John S. Coulter was reappointed chairman and Dr. Frank H. Krusen, vice chairman. Dr. Krusen was acting chairman.

Dr. George M. Piersol presented a report from the Consultants on Clinical Thermometry. Two articles are being written on the subject. He stated that the commonly accepted idea about normal clinical temperatures is far from accurate and a report will be available in due time.

The subject of ion transfer employed therapeutically was discussed. The critical evidence is limited, and in the opinion of the Council the problem should be studied further.

With regard to muscle stimulation, the Council believes that there is no necessity for a multiplicity of current combinations in an apparatus, since there is no critical evidence to justify their use.

The Official Rules of the Council on Physical Medicine were discussed and brought up to date. Several minor changes were made in the body of the booklet. Rule 9, "Policies of Firms Detrimental to Rational Therapeutics," was revoked.

The question whether hearing aid manufacturers be allowed to state that a hearing aid is accepted if it meets the requirements (that is, before it is formally accepted) was discussed. It was decided that all manufacturers should adhere to the rules and that no exceptions should be made.

The articles on atomic energy which were assigned to subcommittees of the Consultants on the Medical Aspects of Atomic Energy and Roentgen Rays and Radium have not been received. Dr. Edward Bortz, President of the American Medical Association, in a letter commended the Council on Physical Medicine for its work on atomic energy. He emphasized the importance of informing the members of the medical profession concerning the clinical value of radioactive isotopes and urged a more aggressive educational program. The revision of the glossary of terms used in atomic energy is proceeding.

The Council expressed its willingness to cooperate with the Council on Medical Education and Hospitals in the evaluation of schools for physical therapists and occupational therapists.

The Secretary was instructed to approach the Consultants on Education of the Council in order to formulate recommendations with regard to minimal suggested science requirements for admission to courses in physical therapy. These recommendations will then be presented to the Council on Medical Education and Hospitals.

The Council members voted that the Council on Scientific Assembly consider establishing a permanent Section on Physical Medicine beginning with the association meeting in 1949.

Due to the fact that the Committee on American Health Resorts was disbanded by the Board of trustees, the Council voted to appoint a group of Consultants on American Health Resorts.

The Council reaffirmed its ruling in regard to germicidal lamps as recorded in "Acceptance of Ultraviolet Lamps for Disinfecting Purposes."

In discussing the subject of ultraviolet radiation and cancer, it was revealed that the following two factors are responsible for cancer of the skin: (1) the quality of the radiation 2,900 to 3,200 angstrom units and (2) the quantity of the irradiation.

The use of radium in treating deafness was discussed at length. It was concluded that until definite evidence is adduced that the treatment is dangerous, advertising of such treatment may be continued in the publications of the American Medical Association.

Dr. Henry Schwerma presented a report on the research in artificial respiration which has been supported by a grant from the Board of Trustees.

The work of the Consultants on Contraceptive Devices, Audiometers and Hearing Aids, Electrocardiographs, Electroencephalographs and Respirators was reviewed.

The resignation of Dr. Grove as chairman of the Consultants on Audiometers and Hearing Aids because he is now a member of the Council was accepted with regret. Dr. Hallowell Davis was appointed to fill the vacancy.

The Council voted to disband the group of Consultants on Ophthalmic Devices because the same members serve as the Committee on Optics and Visual Physiology, and it is too large and busy to consider problems coming before the Council. A new group will be appointed.

Dr. Paul Klopsteg reported on the activities of the Consultants on Artificial Limbs. It was the general consensus that the present group is too large to work efficiently, and it was decided to appoint a new group of Consultants on Artificial Limbs. The revision of the Handbook on Amputations is to be postponed until the large book being prepared by the Committee on Artificial Limbs of the National Research Council has been published. Dr. Klopsteg was appointed to prepare an article on the subject of artificial limbs for the general medical profession. Drs. Ober and Dickson were appointed to serve on a committee to study ways and means to improve the training of those who fit artificial limbs.

The Council voted to revise the Handbook of Physical Medicine.

AN APPRECIATION

The Council on Physical Medicine desires to take this opportunity to express its gratitude and appreciation for the services of the following consultants, whose assistance in carrying out the work of the Council has been given so freely during the past year (1947): Drs. Charles Bahn, Alvan L. Barach, A. R. Barnes, Edward Bigg, Raymond Carhart, Milton B. Cohen, Earl Elkins, Alan Feinberg, Clarence J. Gamble, K. G. Hansson, L. G. Hardy, E. D. Hauser, J. S. Hibbin, A. Hollaender, M. Joannides, H. W. Kendell, Margaret Kunde, V. Lespinasse, Alfred Lewy, G. Martin, A. Olsen, Stafford L. Osborne, Howard F. Polley, Mr. Luther Ramer, Drs. Scott N. Reger, Henry Schwerma, Daniel Snydacker and G. De Takats, Miss Eva Thompson, Drs. Khalil G. Wakim, Ralph Waters, Harold Westlake, Paul H. Wosika, Jessie Wright and C. R. Zeiss.

Artificial Limbs.--Drs. Henry H. Kessler, Paul Klopsteg, Harry E. Mock, S. Perry Rogers, Paul B. Steele and Philip Wilson; Messrs. McCarthy Hanger Sr., W. E. Isle, J. B. Korrady, Joseph A. Spievak and David E. Stolpe.

Medical Aspects of Atomic Energy.--Drs. Kenneth S. Cole, L. F. Curtiss, Hymer L. Friedell, Shields Warren and Stafford L. Warren.

Audiometers and Hearing Aids.--Drs. Gordon Berry, Hallowell Davis, Kenneth M. Day, E. P. Fowler, Isaac H. Jones, Dean Lierle, Moses Lurie, Douglas Macfarlan, C. Stewart Nash and Paul E. Sabine.

Clinical Thermometry.--Miss Johanna Busse, Drs. George Crile Jr., Eugene DuBois, Steven M. Horvath, John Talbot and George Thorn.

Contraceptive Devices.--Drs. William W. Greulich, Joseph Hughes and Andrew C. Ivy, Professor Walter J. Meek, Mr. R. R. Olin and Dr. Ephraim Shorr.

Education.--Drs. Frances Baker, Robert L. Bennett, *Benjamin Boynton, Earl C. Elkins, F. H.* Ewerhardt, Richard Kovacs, Fred B. Moor, W. H. Northway, William Schmidt, Walter M. Solomon, Arthur L. Watkins, George D. Wilson and Walter J. Zeiter.

Electrocardiographs.--Drs. A. R. Barnes, George Fahr, Harold E. B. Pardee, William D. Stroud, Carl J. Wiggers and Frank N. Wilson.

Electroencephalographs.--Drs. Percival Bailey, Edward J. Baldes, Stanley Cobb, Hallowell Davis and Frederic A. Gibbs.

Occupational Therapy.--Drs. Raymond R. Allen, Robert W. Johnson Jr., Winfred Overholser, Howard A. Rusk and William D. Stroud.

Ophthalmic Devices.--Drs. *Thomas D. Allen*, S. Judd Beach, Conrad Berens, Frederick C. Cordes, Alfred Cowan, Walter B. Lancaster, William H. Luedde, Lawrence T. Post, Avery D. Prangen and *Kenneth C.* Swan.

Respirators.--Drs. Edward L. Compere, Charles F. McKhann and James L. Wilson.

Roentgen Rays and Radium.--Drs. William E. Chamberlain, Arthur C. Christie, Edwin C. Ernst, Giocchino Failla, Fred M. Hodges, Robert R. Newell, Eugene P. Pendergrass, Ursus V. Portmann, Lauriston S. Taylor and J. L. Weatherwax.

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, *Secretary.*

INTERMITTENT POSITIVE PRESSURE BREATHING

A MEANS OF ADMINISTERING ARTIFICIAL RESPIRATION IN MAN

H. L. MOTLEY, M.D.
A. COURNAND, M.D.
L. WERKO, M.D.
D. T. DRESDALE, M.D.
A. HIMMELSTEIN, M.D.
and
D. W. RICHARDS JR., M.D.
New York

Intermittent positive pressure breathing, produced by artificial means, is brought about by actively raising the pressure in the lungs during inspiration, the expiratory phase being either passive or mediated through an active mechanism creating negative pressure in the lungs (table 1). Effective ventilation may thus be maintained in apneic subjects, and at the same time the Hering-Breuer reflex is stimulated by distention of pulmonary alveoli. According to Drinker,[1] this is the best line of attack for the promptest possible restoration of normal respiratory movements. Intermittent positive pressure breathing may be given by mouth to mouth insufflation, a simple effective method seldom used. A more commonly employed method consists in applying intermittent positive pressure through an anesthesia breathing bag, which may be equipped with a safety valve set at 14 mm. of mercury as advocated by Waters.[2] A manual bellows respirator[3] with a safety valve that prevents excessive pressure is another means for giving intermittent positive pressure,[4] and a device of this sort has been accepted by the Council on Physical Medicine.[5] More recently another type of manual respirator (suck and blow) has been accepted[6] which has a pressure range from plus 20 to minus 10 mm. of mercury. Automatic mechanical intermittent pressure respirators include the accepted[7] "suck and blow" type with pressures ranging from plus 14 mm. to minus 9 mm. of mercury. Another type studied recently, the pneumatic balance respirator[8] developed by the Army Air Corps, is small and compact in size and has been found simple in operation and effective in providing adequate artificial respiration.[9]

TABLE 1.—*Comparison of Types of Apparatus*

Each of the seven types of apparatus compared in this report is identified by a number so as not to indicate the manufacturer; a list of the chief characteristics and a brief description of each type is given.

Type	Chief Characteristics	Description
1	Pressure-sensitive air-balanced valve	A gas-driven automatic device which administers intermittent positive pressure, the interruption being determined by a pressure-sensitive air-balanced valve. It is known also as pneumatic balance resuscitator (P. B. R.)
2	Pressure-sensitive spring-loaded valve	A gas-driven automatic device which administers intermittent positive pressure, the interruptions being determined by a pressure-sensitive spring-loaded valve
3	Flow-sensitive "Aviation Model"	A gas-driven device which administers intermittent positive pressure, the interruptions being determined by a flow-sensitive valve. It is known also as "Aviation Model"
4	Flow-sensitive "Research Model"	A gas-driven device, similar to type 3 but having in addition many adjustable features that make it versatile for scientific investigations: it is known therefore as "Research Model"
5	"Suck and blow"	A gas-driven device in which positive pressures alternate with negative (subatmospheric). The mechanism consists of a spring-loaded pressure-sensitive valve and in addition a Venturi device for producing suction
6	Hand-operated: slow	A hand-operated device in which positive pressure is produced by compressing a bellows; it is provided with a safety valve opening at a fixed pressure
7	*Hand-operated: fast*	*A hand-operated device* similar to type 6 but provided with a safety valve permitting faster escape of air

A survey of the literature shows a lack of experimental physiologic data reported on man in condemnation or in support of the various respirator devices, with the exception of the one report given on the pneumatic balance type. The design of respirator apparatus for use on man has been based largely on data obtained on animals with respect to (*a*) the upper limit of pressure that could be used safely, (*b*) the beneficial effect of the "suck and blow" type on the circulation as claimed by some[10] and denied by others[11] and (*c*) the absence of pulmonary damage produced by intermittent pressure breathing with and without the negative phase.[12]

The curve of pressure of inspired air, registered at the mask, differs with different forms of respirator apparatus. There has been up to the present time little information on the quantitative effects of these various forms of artificial respiration on the circulatory dynamics in man. Therefore it seemed desirable to obtain direct physiologic measurements by making use of recent technics, including right heart catheterization,[13] on the pulmonic and systemic circulation in man when various types of respirators were used producing either intermittent positive pressure alone or combined with negative pressure during part of the cycle. In the present study physiologic and clinical observations have been made with various types of intermittent pressure respirators on 79 subjects. The data have been analyzed to determine the physiologic requirements of an ideal respirator, one which would provide adequate pulmonary ventilation with a minimal disturbance to the circulation. In addition the efficiencies of several respirators have been compared with manual methods, such as the Schaefer, for producing pulmonary ventilation in the type of subject who needs artificial respiration.

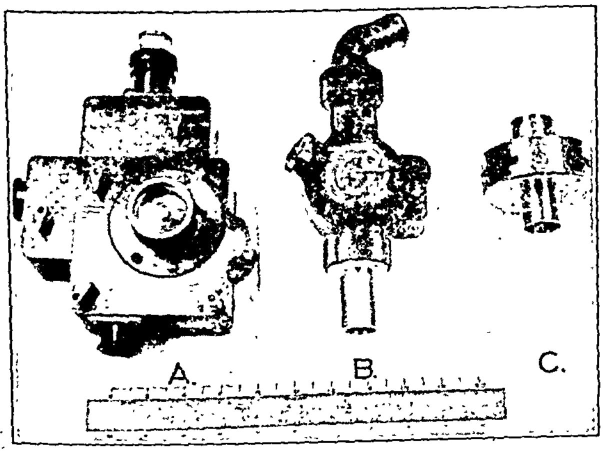

Fig. 1.—Automatic respirators: *A*, clinical research model, type 4; *B*, "Aviation Model," type 3; *C*, type 1.

DESCRIPTION OF THE VARIOUS TYPES OF RESPIRATOR STUDIED

Type 1: Pressure-Sensitive, Air-Balanced Valve ("P.B.R.").—The first of the New Army Air Force models, the pneumatic balance resuscitator, hereinafter referred to as type 1 (fig. 1C) has been described and studied previously.[9] In the present study further observations have been made for comparison with other respirators. Type 1 is based primarily on pressure characteristics for actuating the pneumatic balance alternating mechanism. This mechanism automatically converts continuous positive pressure supplied by a pressure tank with a pressure-regulating valve into intermittent positive pressure. Inflation of the lungs occurs under positive pressure transmitted through a mask to the lungs, and after reversal passive deflation takes place almost to atmospheric pressure aided by the elasticity of the lungs and thoracic structures. The maximal pressure in the face mask is approximately 75 per cent of the continuous positive pressure or line pressure delivered by the regulating valve on the pressure tank, while the minimal pressure is about 10 per cent.[8] The Army Air Force's pressure-demand regulator, which supplies oxygen at atmospheric pressure during inspiration or maintains a continuous positive pressure adjustable up to 30 cm. of water by means of a regulator dial (fig. 2), provided a convenient means for maintaining a constant line pressure. The complete respirator unit can be assembled as a small, compact, portable outfit with a small oxygen cylinder, as shown in figure 2. The aluminum model respirator has been found simple to use, easy to maintain in operation and serviceable for long periods of time without special care.[9] A model made of plastic material was found to be unsatisfactory due to (1) warping of the disk supporting the rubber membranes and valve seat, resulting in a failure to cycle properly, and (2) the danger of breaking the fragile outside wall of the plastic case. All variables except line pressure regu-

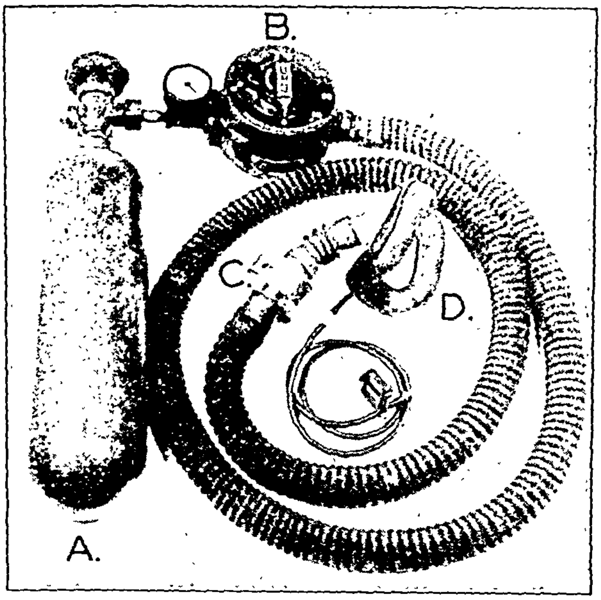

Fig. 2.—Small portable respirator outfit: *A*, high pressure oxygen cylinder; *B*, Bendix pressure demand regulator; *C*, type 1 respirator, and *D*, experimental face mask.

lation are built in the device as fixed adjustments. There are no springs. Two rubber diaphragms constitute the only moving parts. Mask leaks greater than 10 per cent prevent proper cycling. The mask pressure curve obtained is symmetric with a constant upward slope during inspiration and constant downward slope during expiration (see fig. 3, II *A*). Inspiratory time is approximately equal to expiratory time.

Type 2: Pressure-Sensitive, Spring-Loaded Valve.—A small compact experimental automatic intermittent positive pressure respirator with a mechanism similar to that of type 5 without a Venturi device was tested. All adjustments are fixed on this model except frequency of alternation. The breathing pattern and mask pressure curves are similar to those of type 1 (fig. 3, II *B*). The maximal peak pressure on the model used was 15.1 mm. of mercury and the minimal was 2.2 mm. of mercury. In general the observations on this model were the same as for type 1. The discussion of the influence of type 1 on the respiration and circulation is also applicable for type 2 (for a comparable line pressure setting giving the fixed peak pressure of the latter).

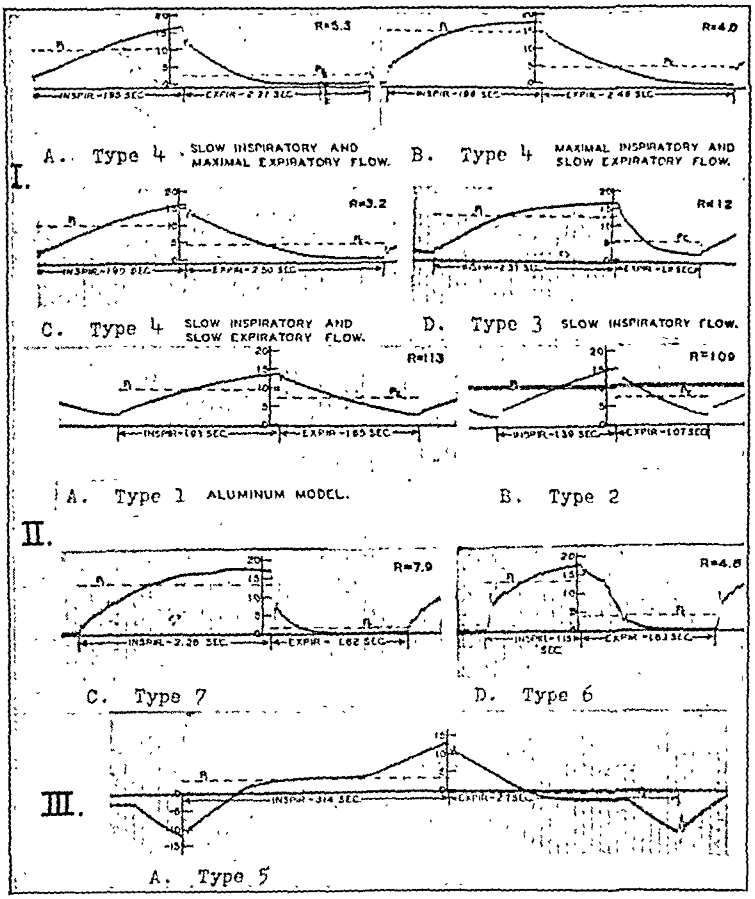

Fig. 3.—Various types of mask pressure curves produced by respirators (electric recording): P_I, inspiratory mean mask pressure; P_E, expiratory mean mask pressure. All pressures are recorded in millimeters of mercury.

Type 3: Flow-Sensitive, "Aviation Model."—The second new type developed by the Army Air Corps is shown in fig. 1 *B*[14] and hereinafter referred to as type 3. The principle of operation for this type is based primarily on flow characteristics for actuating the cycling mechanism. This model was designed for use with a compensated pressure valve used in the Army Air Forces A 13 and A 15 pressure demand oxygen masks. Expiration occurs more rapidly than with type 1, and the flow capacity is greater. The respirator mechanism reverses when the flow of gas through the cycling vane completely stops, a feature which requires that the mask fit on the face without leaks. The minimal pressure on expiration is 2.5 cm. of water and is unrelated to line pressure, while the maximal pressure is approximately the same as the line pressure. The flow sensitivity characteristic of the cycling mechanism is in contrast to type 1, which is primarily pressure sensitive. The mask pressure curve of type 3 is asymmetric, showing a gradual increase in pressure during inspiration and a sudden drop in pressure at the beginning of expiration, with the rest of the curve being concave upward until it levels off at a pressure of 2.5 cm. of water (fig. 3, I *D*). Inspiratory time usually exceeds expiratory time, but the ratio of inspiratory to expiratory time, the cycling rate and the ventilation can be varied widely.

Type 4: Flow-Sensitive, "Research Model"—A third type, newly developed by the Army Air Corps (fig. 1A),[18] is herinafter referred to as type 4. This instrument was designed to permit a study of more variables involved in intermittent pressure breathing than was possible with type 3. With type 4 the following can be varied separately or in various combinations: (*a*) line pressure, (*b*) inspiratory cycling rate, (*c*) expiratory cycling rate, (*d*) inspiratory flow rate, (*e*) expiratory flow rate and (*f*) expiratory pressure. Type 4 works automatically, and its characteristic alterations are determined by flow-time relationship provided by a separate cycling piston in the mechanism. It is stated that the cycling of the respirator is more positive than with type 3. Large mask leaks are tolerated without interfering with the cycling, due to the enclosure in the mechanism of a separate flow circuit acting on the cycling piston. (For a more detailed description consult article by Motley and others.[15] Type 4 does not require a Linde compensated pressure valve and may be used with any pressure face-mask or anesthesia-mask with an inflatable cuff. The mask pressure curve of type 4 is somewhat similar to that of type 3, characterized by the rapid initial drop in pressure at the beginning of expiration that progressively decreases to atmospheric. The variability in the type of tracing that can be obtained is much greater than with type 3 (fig. 4.; 1A, B and C). A slow inspiratory and maximal expiratory flow rate-setting produces a mask pres-

W., Jr.: Physiological and Clinical Studies of Intermittent Pressure Respirators and Manual Methods for Producing Artificial Respiration in Man; Memorandum Report, TSEAA 696-79-F, AAF Headquarters A. M. C. Engineering Division,, Aero-Medical Laboratory, Wright Field, Sept. 6, 1946.

sure tracing that has a gradual increasing pressure until a peak is reached, where cycling occurs and the pressure then drops rapidly to atmospheric (fig. 3, I *A*). The aforementioned respirator setting for flow rates results in maximal peak pressures with the lowest mean mask pressure for the entire cycle (see fig. 3, I *A*, *B* and *C*). Adjusting the expiratory flow rate to minimal instead of maximal as in the preceding combination results in a type 1 curve (fig. 3, I *C*). The transmission of line pressure in type 4 as peak mask pressure varies with the rate of inspiratory flow, approaching 100 per cent on a maximal inspiratory flow setting. When the inspiratory time tends to be longer than expiratory time, an unnecessarily high mean mask pressure for the entire cycle results.

Type 5: "Suck and Blow."—Type 5,[7] used as an example of the "suck-and-blow" type, has a negative pressure at the beginning of inspiration, which gradually becomes positive up to a certain peak pressure where reversal occurs. During expiration the pressure decreases gradually back to the starting point (fig. 3, III *A*); there are no variables to adjust in this model, as inspiration stops at a fixed positive mask pressure (plus 13.5 mm. of mercury) and expiration at a fixed negative pressure (minus 11.1 mm. of mercury). The valves are spring-loaded, and a Venturi device which operates only during expiration provides the suction. With the model used, 37 per cent of the expiratory volume was added by use of the Venturi device. Inspiratory time is longer than expiratory time, and the cycling rate (i. e., frequency per minute) is slower than on the other respirators

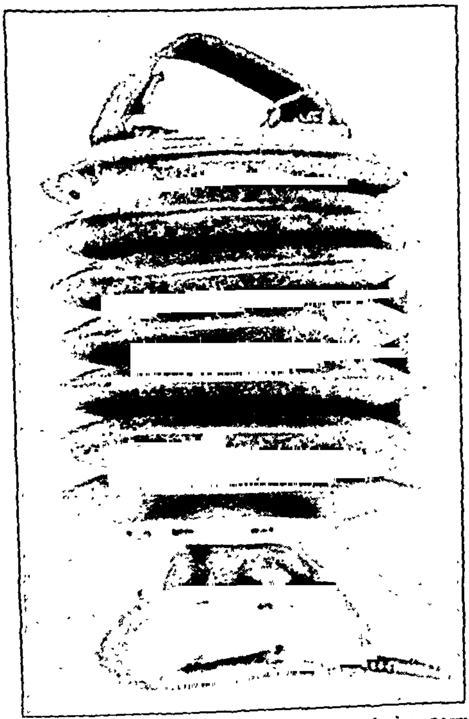

Fig. 4.—Type 7, hand-operated, fast: safety device permits faster escape of air than in type 6.

Type 6: Hand-Operated, Slow.—Type 6[4] is equipped with a safety valve which opens when the positive pressure reaches 17.5 mm. of mercury on the model used (fig. 3, II *D*). Positive pressure is produced by compressing a bellows, which builds up the pressure rapidly to a peak. When the valve opens expiration takes place rapidly and the mask pressure drops to atmospheric. Inspiratory and expiratory time may be varied by the operator. The maximal volume change for one stroke on the bellows measured 1,500 cc. The sliding valve arrangement of type 6 is rather awkward, as inexperienced operators may prevent effective ventilation with the device by blocking the valve by their hand.

Type 7: Hand-Operated, Fast.—Another model, type 7 (fig. 4), a bellows type, hand-operated respirator somewhat similar to type 6 was also studied. This model has also a safety valve that opens when the positive pressure reaches 17.5 mm. of mercury. The tracing of type 7 (fig. 3, II *C*) shows a gradually increasing mask pressure and then a rapid drop to atmospheric after expiration starts. The expiratory pressure drops to atmospheric more rapidly on type 7 than on type 6 (fig. 3, II *C* and *D*). The maximal volume change for one stroke on the bellows measured 2,000 cc. The bellows and valve operation on type 7 was smoother and more foolproof than that on type 6. Inspiratory and expiratory time may be varied by the operator.

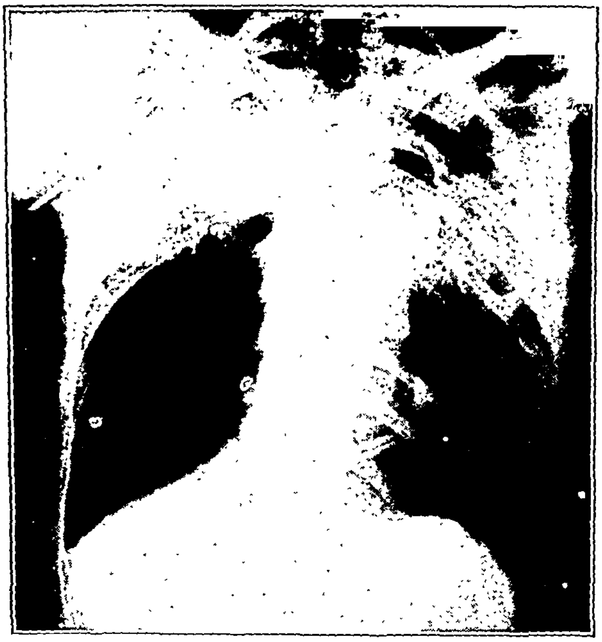

Fig. 5.—Cardiac catheter with the tip in the right ventricle.

METHOD OF STUDY

Pulmonary ventilation was measured and compared with the various types of respirators, both automatic and manual in both conscious and unconscious subjects, using a Tissot spirometer or a portable recording spirometer. In cases of complete apnea the respirators were compared with manual methods for producing pulmonary ventilation. The position of the apneic subject was studied with particular reference to respiratory resistance and the influence on the resulting ventilation.

Respiratory gas exchange was determined by analysis on the Haldane apparatus for carbon dioxide and oxygen content of expired air collected in a spirometer. Also, samples of arterial blood from the brachial or femoral artery were analyzed for oxygen content and capacity and carbon dioxide content on the Van Slyke-Neill apparatus. The p_H was determined directly by use of a glass electrode; the oxygen saturation and pCO_2 (carbon dioxide concentration expressed in terms of pressure) were calculated. In 26 cases a total of one hundred and two simultaneous samples of blood were obtained from the artery through an indwelling needle and from the right ventricle by means of a cardiac catheter introduced through the median basilic vein into the right ventricle (fig. 5), using a technic which has been described and discussed elsewhere.[16] The cardiac output was calculated by applying the Fick formula, using the data obtained from the samples of expired air, of mixed venous blood from the right ventricle and of arterial blood all collected simultaneously:

$$B = \frac{C}{D}$$

where B = cardiac output in liters per minute,
C = oxygen intake in cubic centimeters per minute and
D = difference in oxygen content between arterial and venous blood, in terms of cubic centimeters of oxygen per liter of blood.

(Example: Oxygen intake 200 cc. per minute with an oxygen arteriovenous difference of 40 cc. per liter of blood. Cardiac output = 5 liters per minute.)

Several measurements of cardiac output were obtained at intervals over a period of two to three hours. The subject had been maintained in a fasting state for the preceding sixteen hours. After introduction of the cardiac catheter and intra-arterial needle, a thirty minute rest period with the patient lying supine was used before the first measurement was taken while breathing air at ambient (prevailing atmospheric) pressure. The second cardiac output measurement was taken after ten to twenty minutes on a respirator, followed by a third measurement at ambient pressure in ten to twenty minutes. A fourth measurement was generally taken using either another type of respirator or the same respirator on a different line pressure. In a few cases a fifth measurement was taken either with another type of respirator or during spontaneous breathing. The patients were unanesthetized except for a small amount of procaine hydrochloride used in the skin where the needle and catheter were introduced.

Pressure recordings were obtained simultaneously from the brachial or femoral artery, the right ventricle, the mask pressure and, in 4 subjects having a therapeutic pneumothorax, from the pleural space. The Hamilton manometer for multiple pressure recordings[17] or the Clark pressure pick-up capsule with electrical amplification and recording were used.[18] Tracings were obtained from the same subject in three instances with both the Hamilton and the electrical methods of recording, separately and simultaneously. The pressures measured by the two systems checked closely. A simultaneous electrocardiogram was also obtained with the aforesaid recordings. The zero reference plane for cardiac pressure was taken 5 cm. below the angle of Louis, while the reference plane for arterial pressure was the level of the artery used. Systolic and diastolic pressures were calculated from the calibration curves and mean pressure by planimetric integration of the area under the curve for each pressure tracing.

A simulated breathing device was used to test the mechanical features of the various respirators. This set-up consisted of a G 1 low pressure oxygen cylinder (internal volume 2,100 cubic inches, 34,419 cc.) with a 500 cc. special type mask breathing bag connected on one end. The tidal volume approximates that of man, and the device provides both the distensibility and retractability factors present in the lungs.

MATERIAL FOR STUDY

The cases studied in this paper may be divided into four main groups, (1) essentially normal trained volunteers, (2) unanesthetized conscious subjects studied by cardiac catheterization, (3) patients in deep coma and (4) patients in complete apnea. The observations and measurements for each group are given in table 2.

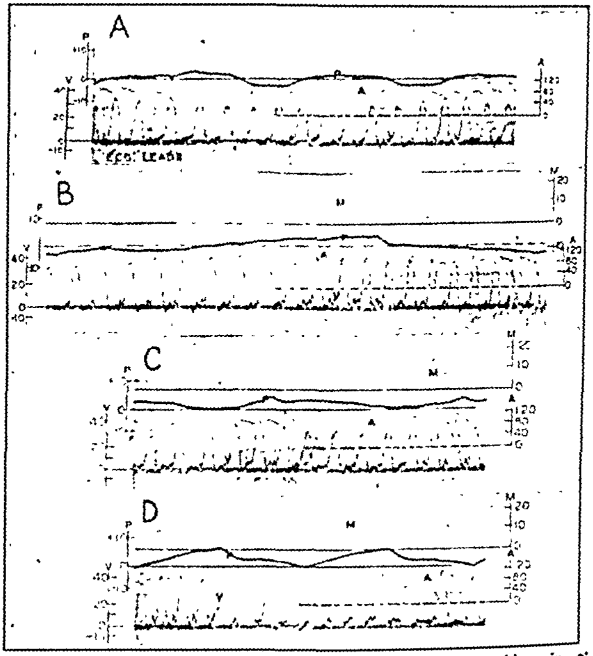

Fig. 6.—Comparison of spontaneous and respirator breathing in a subject with essentially normal circulation: *A*, pressure tracing during spontaneous (ambient) breathing: f [illegible] pleura, brachial artery and right ventricle; *B*, press [illegible] with type 5: from above downward—mask, [illegible] right ventricle; *C*, pressure tracings while [illegible] order as in *B*; *D*, pressure tracings while breathing with type 4, same order as in *B*. On the tracings: V, right ventricle; A, brachial artery; P, pleura; M, mask; all pressures in millimeters of mercury.

RESULTS

A. Influence of the Various Respirators on Ventilation and Gas Exchange.—1. Comparison of Mask Pressure Curves Obtained with the Simulated Breathing Apparatus and in Conscious Subjects: Using the simulated breathing device previously described, the mask pressure curves were studied using the automatic respirators. These curves, illustrated in fig. 3, are identical to curves obtained on well relaxed subjects.

Table 2.—*Material for Study and Observations Made*

Type of Case		No. of Subjects	Type of Observation
Normal trained volunteers..		10	Pulmonary ventilation; air and blood gas exchange
Conscious subjects..........		26	Pleural pressure (4 cases); pulmonary ventilation; air and blood gas exchange; cardiac output; intracardiac and peripheral artery blood pressure recordings; mask pressure
(a) Essentially normal circulation.........	17		
(b) Arteriosclerotic heart disease.......	7		
(c) Shock from hemorrhage..............	2		
Deep coma....................		22	Pulmonary ventilation; air and blood gas exchange; clinical observations
Complete apnea............		21	Pulmonary ventilation; imposed frequency pressures required; influence of position

and represent comparable ventilation volumes. In unrelaxed subjects deviations from the preceding type of curves frequently occurred. Failure of the inspiratory part of the curve to rise early in inspiration has been observed with all the automatic intermittent positive pressure respirators. This was due to a superimposed inspiratory effort on the part of the subject. The negative phase of the curve obtained with the type 5 respirator was often reduced in length and depth as the result of positive efforts by the patient to terminate the suction phase. Type 1 and also types 3 and 4 tended to follow the slightest breathing effort of conscious subjects, but with types 2 and 5 the subject had to follow the respirators to get proper ventilation.

2. Ventilation and Gas Exchange in Different Types of Subjects: (*a*) Conscious: Data from 47 experiments concerning the effect of the automatic respirators on ventilation and gas exchange in conscious subjects systematically studied, including cardiac catheterization, are given in table 3. The increase in pulmonary ventilation varied from 23.3 per cent with type 1 to 105 per cent with type 4. The ventilation rise was due to an increase in tidal volume, for the respiration rate was decreased from 21.4 per cent with type 4 to 56.6 per cent with type 5. In general there was a slight increase in the percentage of saturation of oxygen in the arterial blood (2 to 3 per cent, table 3). When the subjects were using the respirators with compressed air, the carbon dioxide content was decreased slightly with all the automatic respirators, varying from minus 0.7 volumes per cent with type 1 to minus 4.2 volume per cent with type 3. The p_H increased from 0.05 units with type 1 to 0.12 units with type 3, and accordingly the calculated pCO_2 decreased by 3.1 and 12.6 mm. of mercury respectively. With the exception of type 4, there was a good correlation between the degree of hyperventilation caused by the various respirators and the extent of pCO_2 changes. This may have been due in type 4 to the greater dead space in the hose line connection of the mask to the respirator, which resulted in greater rebreathing than on the other models.

TABLE 3.—*Respirators Using Compressed Air*

Comparison of effects on pulmonary ventilation and the CO_2 content, pCO_2 and p_H of arterial blood

	Respirator Type			
	1: Pressure-Sensitive	3: Flow-Sensitive "Aviation Model"	4: Flow-Sensitive "Research Model"	5: "Suck and Blow"

* With respect to ambient (spontaneous breathing at atmospheric pressure).

Changes in blood gases and p_H observed after the respirators were in use for several hours were of the same magnitude as the changes observed after ten to fifteen minutes. The respiratory alkalosis observed was of little clinical significance. Even in the patients using type 3, where the changes were most pronounced (pCO_2 25.2 mm. of mercury, p_H 7.58) no manifestation of tetany was observed. Observations after sixty minutes[6] at a 25,000 feet (7,620 meters) simulated altitude with subjects hyperventilating showed still lower pCO_2 and higher p_H without any evidence of tetany.

Observations on pulmonary ventilation and gas exchange in 10 essentially normal trained volunteers were similar to the data reported on the catheterized group in table 3.

(*b*) Deep coma: The automatic respirators were used on 22 patients in deep coma with respiratory difficulties. The diagnoses were as follows: 8 cerebrovascular accidents; 3 cardiac disease in terminal failure; 2 ethyl alcohol poisoning; 2 carbon monoxide poisoning; 2 barbiturate poisoning; 1 methyl alcohol poisoning; 1 immersion; 1 heat exhaustion and epilepsy; 1 irreversible hemorrhagic shock, and 1 pneumonia.

The automatic respirators produced adequate ventilation (5 to 18 liters per minute, average 10.5 liters per minute) in all types of unconscious subjects without adverse effects from hyperventilation. The following illustrative data were obtained in an instance of cerebrovascular accident, the patient in coma with Cheyne-Stokes breathing: On ambient air the ventilation varied from 8 to 40 liters per minute and in the arterial blood the pCO_2 was 34.9 mm. of mercury, the p_H 7.53 and the oxygen saturation 81 per cent. With type 1 on compressed air the breathing was regular with a ventilation rate of 16 liters per minute, pCO_2 37.8 mm. of mercury, p_H 7.47 and the oxygen saturation 93 per cent in the arterial blood. With type 1 on 100 per cent oxygen the breathing was regular with a ventilation rate of 17.5 liters per minute, pCO_2 36.0 mm. of mercury, p_H 7.49 and the oxygen saturation 102 per cent. The line pressure used above was 21 cm. of water (15.4 mm. of mercury for type 1 on both compressed air and 100 per cent oxygen. On ambient 100 per cent oxygen, following the use of type 1, the breathing remained regular with a ventilation of 14 liters per minute, pCO_2 38.5 mm. of mercury, p_H 7.46 and the oxygen saturation 105 per cent in the arterial blood. When the patient was changed to air, the Cheyne-Stokes breathing reappeared in two minutes.

In patients with a gasping type of inspiration there was a very high instantaneous flow rate of short duration (0.4 to 0.6 second) with maximal peak flows during this interval up to 80 to 120 liters per minute.[15] Type 4 flow-sensitive "Research Model" was the only respirator with sufficient instantaneous flow capacity to eliminate the negative phase at the beginning of inspiration due to additional inspiratory effort.

Usually the respirators were used with a mask, but in 2 cases type 1 and type 4 were used attached to an endotracheal tube. Lower regulator line pressures give adequate ventilation with an endotracheal tube as compared to the line pressures required when using the mask.

Type 1, Pressure-sensitive pneumatic balance resuscitator, was the only automatic respirator considered safe enough in the mechanical operation and sufficiently innocuous in its physiologic effects to be left with a minimum of ward supervision on patients in coma for extended periods of time, one to two days or longer if necessary. Type 1 has been used up to seventy-nine hours continuously in the treatment of a patient with barbiturate poisoning without demonstrable ill effects, either clinical or pathologic.

(c) Complete apnea: It has been pointed out that the fresh cadaver much more closely simulates the completely apneic living subject than does the normal conscious person.[19] Therefore, observations have been made on 18 subjects at or shortly after the time of death, in addition to 3 living subjects with complete apnea. Adequate pulmonary ventilation was obtained with all the respirators provided the subject was in the proper position, except in 1 case. The subject in the aforementioned case had bulbar palsy with dysphagia and had died as the result of a complete blocking of the upper trachea with solid particles of food. The onset of rigor mortis has been the factor limiting the length of time that type 1 will ventilate the lungs after death.[9] The preceding factor also holds for all the other types, both automatic and hand-operated respirators. The best position of the body has been discussed for type 1.[9] This body position consists in hyperextension of the head on the cervical vertebrae (push the head back) with support of the lower chin and a slight Trendelenburg position. This position was found to be the best for all respirators, both automatic and hand-operated, and was in most instances the determining factor between success or failure for proper performance of the automatic respirators in apneic subjects.

The frequency of alternation and the pulmonary ventilation produced by the various automatic respirators are shown in table 4. Line pressures used to ventilate the lungs averaged 15.8 mm. of mercury for type 1, 13.6 for type 3, and 12.0 for type 4. Types 2 and 5 have fixed line pressures. The line pressure with type 1 had to be increased approximately 25 per cent over those of types 3 and 4 in order to get the same peak mask pressure, due to less transmission of line pressure in type 1. All the automatic respirators which were tested gave adequate pulmonary ventilation with a mask if the line pressure was 11.8 mm. of mercury (16 cm. of water) or higher. The values for types 3 and 4 were obtained with the adjustments set for medium inspiratory flow and alternating frequency. By increasing the inspiratory flow and the alternating frequency on types 3 and 4 the total pulmonary ventilation could easily be increased on each of the different line pressures used. Types 3 and 4 were slightly more capable of overcoming breathing resistance in the upper part of the pharynx and maintaining proper alternation frequency than the others. In order to prevent types 3 and 4 from ventilating the lungs a complete blockage of the airway must be present, as the design of the apparatus is based on flow sensitivity. Type 1 tolerates airway obstruction slightly better than type 5. Type 2 responds in the same manner as type 1.

Both manual respirators (types 6 and 7) provided adequate ventilation in the apneic subjects tested. The operator controlled the frequency of alternation. The respiratory excursions produced by the manual respirators were preponderantly diaphragmatic in character; this was also true for the automatic respirators. Although the exact ventilation volume was not measured with the manual models, the amount was considered adequate as judged by the abdominal excursions and breath sounds, and these correspond with observations made on the same subjects with the automatic respirators in cases in which an adequate ventilation volume was measured.

In contrast to the adequate pulmonary ventilation secured with the various respirators, manual methods used on the same test subject were grossly inadequate. Observations were made on 4 suitable test subjects (cadavers), selected because they were known to have had clear lungs just prior to death. With the best positions of the body in the first case, the average tidal volume obtained with the Schaefer method was only 78 cc., and when the best position was not used no ventilation resulted. Type 1 easily ventilated this subject at a rate of 6 to 10 liters per minute, depending on the line pressure. In the second case with the best body position an average tidal volume of 50 cc. was secured with the Schaefer method. When the Schaefer method was used without hyperextending the head on the neck and supporting the lower jaw, ventilation did not result.

The two hand-operated respirators, types 6 and 7, ventilated the second subject adequately and with ease; respiratory movements were pronounced, and breath sounds were normal in character. All the automatic respirators ventilated this second subject adequately and with ease. In the third case with the Schaefer method an average tidal volume of 140 cc. was secured with the best position, and without hyperextension of the neck but with support of the lower jaw the tidal volume was reduced to 90 cc. Without hyperextension of the head and without supporting the lower jaw no ventilation resulted. This subject was easily ventilated with the automatic respirators at a rate of 6 to 10 liters per minute. In the fourth case the Schaefer method failed to ventilate the lungs even after the best position was secured. The Eve (rocking) method gave 50 to 60 cc. per tidal volume with the best position of the head. If the head were not held properly no ventilation could be measured with the Eve method. The automatic respirators ventilated the fourth subject easily at a rate of 5 to 11 liters per minute depending on the setting of the various respirators and the line pressure used. Tests made with and without an airway tube in these 4 cases revealed no difference in the pulmonary ventilation.

In summary, in 4 apneic subjects even though great care was taken in testing the manual methods with the proper position of the body, head and lower jaw pulmonary ventilation was grossly inadequate, while adequate pulmonary ventilation was easily secured with the respirators; similar observations have previously been reported on comparing type 1 to the manual squeeze procedure as commonly carried out on a hospital bed.[9] Other studies have been reported on the inadequacy of the Schaefer method in the type of subject in need of artificial respiration.[19] The proper position for the head, lower chin and body, previously described,[9] was found to be the most advantageous for administering artificial respiration in apneic subjects either by respirator or manual methods.

Type 1 was used for ten hours to maintain artificial respiration in 1 case of methyl alcohol poisoning with complete apnea. With a line pressure of 21 cm. of water (15.4 mm. of mercury) the pulmonary ventilation averaged 6 to 8 liters per minute. At intervals type 1 was stopped, but no spontaneous respirations occurred. The mean blood pressure was low, maintained at 25 to 30 mm. of mercury in the femoral artery during the entire period.[7] When sodium bicarbonate was given to correct the extremely low arterial blood p_H of 6.81, the

arterial pulse and blood pressure improved slightly with type 1 breathing as the p_H was raised to 7.30. Although the subject was decidedly cyanotic before using the respirator, shortly after starting type 1 the arterial blood was 100 per cent saturated. In this subject when type 1 was changed from 100 per cent oxygen to compressed air on the same line pressure the pulse became weak and the heart sounds faint. When 100 per cent oxygen was resumed with type 1 the improvement was immediate. During a routine lumbar puncture for examination of the cerebrospinal fluid the pressure was observed to fluctuate with the respirator cycling, with peak increases that represented 25 per cent of the peak mask pressure (16 cm. of water) on type 1. After ten hours the heart gradually failed and finally stopped. There was no urinary output during the ten hour period. Postmortem examination revealed extensive injury to the liver and kidneys as a result of the methyl alcohol poisoning.

TABLE 4.—*Alternation Frequency and Pulmonary Ventilation Produced with Various Respirators in Eighteen Patients with Complete Apnea*

* Corrected volume (amount added by Venturi suction device has been deducted).

Type 1 was used on 1 case of immersion, in which complete apnea developed shortly after the patient was brought into the hospital. There was pronounced cyanosis, a mottled purplish discoloration of the skin, white frothy fluid exuding from the mouth and acute pulmonary edema. The rectal temperature was 95 F. The condition was the result of immersion in sea water (East River, near Bellevue Hospital) while the patient was in a drunken stupor. Type 1 was used on a line pressure of 21 cm. of water with 100 per cent oxygen, and it maintained adequate ventilation. The cyanosis cleared after ten minutes, but about thirty minutes elapsed before the discoloration of the skin completely disappeared. After sixty minutes on type 1 the chest was clear anteriorly, with only a few moist rales left at the bases of the lungs posteriorly. Semiconsciousness returned after thirty minutes, and use of the type 1 respirator was discontinued after two hours. The patient made an uneventful recovery without contracting bronchopneumonia.

Type 1 was used on 1 adult man with acute anterior poliomyelitis complicated by a complete respiratory paralysis at Willard Parker Hospital, New York. This subject quickly became cyanotic when the Drinker type respirator was stopped, and manual methods applied by experienced operators were inadequate to prevent cyanosis from developing. On a line pressure of 21 cm. of water, adequate pulmonary ventilation was secured as judged by the subjective sensation of the patient, color of the skin and respiratory excursions of the chest and abdomen. Type 1 was used to permit nursing care and physical therapy while the respirator was stopped. Also, the subject was moved with ease from one building to another without discomfort. The face mask (fig. 2) was the most comfortable for this patient. The oxygen was too dry for continued use with type 1 without using a humidifier, as he complained of a dry throat and interference with swallowing. When the subject was changed to the respirator after being on 100 per cent oxygen with type 1 he complained of air hunger for a few minutes, but this sensation rapidly disappeared.

B. *Influence of the Various Respirators on the Circulation.*—In the 26 patients studied by means of cardiac catheterization, the records obtained permitted careful analysis of the effects on the circulation produced by increasing and decreasing mask pressures.

1. Heart Rate: The observations regarding heart rate made in 36 experiments on 24 subjects (17 with essentially normal circulation and 7 with cardiac disease) appear in table 5. The changes in heart rate during inspiration are listed separately and correlated with the corresponding mean mask pressure. Increase in heart rate during the period of increasing pressures was more appreciable than during the period of decreasing pressure with type 1, type 3 and type 4. During the period of increasing pressure with an average mean mask pressure of 9.3 mm. of mercury for the three respirators just mentioned, the average increase in heart rate was approximately 10 per cent; during the period of decreasing pressure, with an average mean mask pressure of 5.1 mm. of mercury, the average increase in heart rate was approximately 4 per cent. With type 4 the change in heart rate was insignificant during the expiratory phase, which is characterized by a rapid drop in pressure approaching zero with a low mean mask pressure. There was no essential change in heart rate during the period of increasing and decreasing pressure while breathing on type 5, as shown in table 5. This was probably related to the low mean mask pressure present during both inspiration and expiration.

TABLE 5.—*Heart Rate and Mean Mask Pressure During Inspiration and Expiration with Various Types of Respirators*

		Inspiration			Expiration		
			Heart Rate			Heart Rate	
Respirator Type	Number of Experiments	Mean Mask Pressure, Mm. Hg	Per Min.	Per Cent Change from Ambient	Mean Mask Pressure, Mm. Hg	Per Min.	Per Cent Change from Ambient
1: Pressure-sensitive	11	6.4	96	+9.0	6.0	90.0	+3.0
3: Flow-sensitive "Aviation Model"	8	12.4	86	+17.0	7.3	79.0	+7.0
4: Flow-sensitive "Research Model"	11.	9.0	89.6	+4.1	1.9	85.5	—0.7
5: "Suck and blow"	6	5.1	84.7	—1.7	0.5	86.5	—0.8

2. Electrocardiogram: Significant electrocardiographic changes on lead 2 were not observed in the 26 subjects during intermittent positive pressure breathing. There was also no change in the time intervals between

the electrical and mechanical events in the right heart, as compared to the records of spontaneous breathing (fig. 6 and 7).

3. Blood Pressure. The influence of intermittent positive pressure on blood pressure was studied on 17 subjects with an essentially normal circulation. The average arterial and right ventricular blood pressures during breathing with the four automatic respirators are given in table 6 with the corresponding mean mask pressures. Records illustrating simultaneous recordings of intra-arterial (femoral or brachial), intraventricular, pleural and mask pressures and electrocardiographic lead 2 are presented in figures 6, 7 and 8.

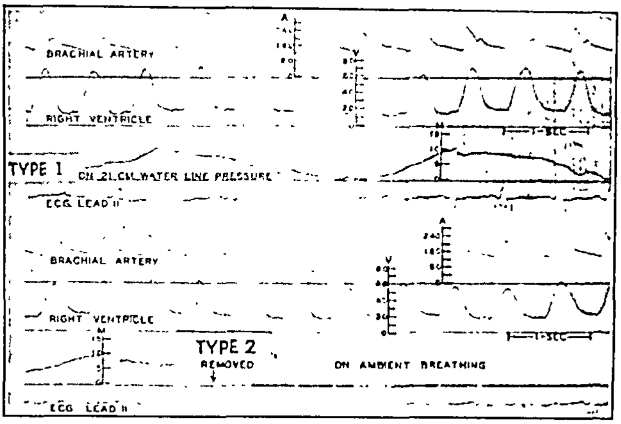

Fig. 7.—Pressure tracing in a case of essential hypertension. Electric recording was used in contrast to multiple simultaneous recordings with Hamilton manometer in previous figures: *A*, brachial artery pressure; *M*, mask pressure; *V*, right ventricle pressure. All pressures in millimeters of mercury on the scale.

* With respect to values obtained during spontaneous breathing: actually, the procedure involved in most cases in sequence: (1) a period of spontaneous breathing; (2) a period of pressure breathing, and (3) a second period of spontaneous breathing. The second period was compared with the average of the first and third periods.

The changes in systolic, diastolic, pulse and mean pressures are of low magnitude with all the automatic respirators, as is seen in table 6. The arterial systolic pressure with type 3 breathing decreased 3 mm. of mercury in contrast to a slight increase with the other respirators; however, the mean mask pressure on the former was the highest. Right ventricle pressures were increased with respect to ambient subjects with type 3 and type 4, while with type 1 and type 5 the changes were minimal. The mean right ventricular pressure was increased from plus 0.8 mm. of mercury on type 5 to plus 3.9 mm. of mercury on type 4, somewhat correlated with the mean mask pressure.

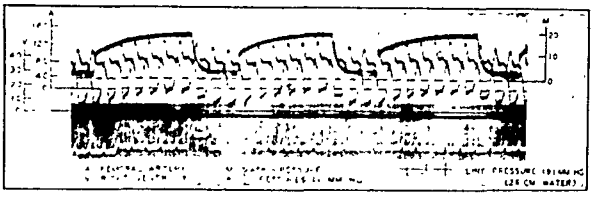

Fig. 8.—Pressure tracings while breathing with the type 3 (intermittent positive pressure) respirator: from above downward—mask, femoral artery and right ventricle.

4. Peripheral Vascular Resistance: The peripheral resistance was increased with all the automatic respirators (table 6). The calculation of peripheral resistance was made according to the formula[16a] generally in use with entries for the mean arterial blood pressure, the end diastolic right heart pressure and the cardiac output.

5. Cardiac Output: The effects of the four automatic respirators on the cardiac output in thirty-three experiments on 17 subjects with essentially normal circulation are presented in table 7. Type 1 with an average mean mask pressure of 7.7 mm. of mercury produced a decrease in cardiac output of 10.8 per cent. This decrease was apparently proportional to the increase in mean mask pressure, as seen in figure 9, which is based on data obtained in thirteen experiments in subjects with essentially normal circulation. With a slightly higher mean mask pressure (8.1 mm. of mercury) the reduction in cardiac output with type 4 averaged only 5.9 per cent. With a mean mask pressure significantly higher, 9.8 mm. of mercury, the reduction in cardiac output with type 3 averaged 12.9 per cent. The mean mask pressure for type 5 was exceedingly low (2.6 mm. of mercury), and there was an insignificant change in cardiac output with respect to the values for natural breathing. An example of the different effect of type 1 and type 4 on the cardiac output in a subject under basal metabolic conditions who was studied repeatedly on the same day is given in table 8.

Table 7.—*Effects of Various Respirators on Breathing Characteristics of Cardiac Output in Subjects with Essentially Normal Circulation*

Respirator Type	Number of Experiments	Mean Mask Pressure, Mm. Hg	Mean Mask Pressure, % of Line Pressure	Frequency of cycles per Min.	Inspiratory Time, Sec.	Expiratory Time, Sec.	Ratio: Inspiratory to Expiratory	% Change in Cardiac Output with Respect to Output During Natural Breathing

5: "Suck and blow"	5	+2.6	....	6.9	7.51	3.63	2.07	+1.9

In ten experiments on 7 patients with arteriosclerotic heart disease no significant change (—2.0 per cent) in cardiac output was observed as a result of using the respirators on the following line pressures: the average pressure with type 4 in four experiments was 11 mm. of mercury and with type 1 in six experiments, 14.7 mm. of mercury. The resulting mean mask pressures were low—the average with type 4 was 5.3 mm. of mercury and with type 1, 5.6 mm. of mercury.

The changes in cardiac output were insignificant in 2 instances of hemorrhagic shock when type 1 was used with a line pressure of 8.8 mm. of mercury (12 cm. of water).

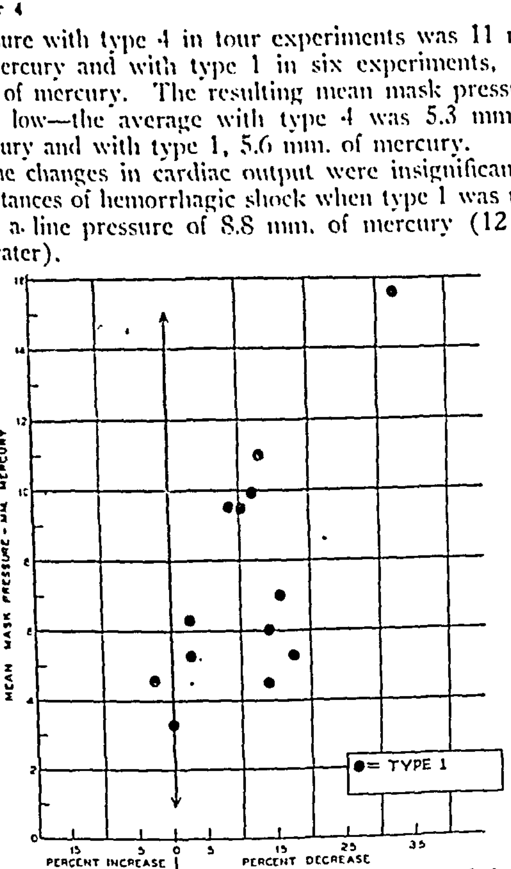

Fig. 9.—Relation between mean mask pressure increase and change in cardiac output from control ambient in patients with essentially normal circulation. Note the proportional decrease as the mean mask pressure increases.

Data were secured in 4 persons having a therapeutic pneumothorax by measuring pleural pressures simultaneously with the mask, right ventricle and arterial pressures. Information was thus obtained concerning the net filling pressure at the end of diastole in the right ventricle in relation to mask and pleural pressure variations. The right ventricular pressure changes were related to pleural rather than to mask pressure changes. In 2 subjects with structural changes in the lungs and in the pleura this relation was clearly demonstrated, as there was a lag of about one second between mask and pleural pressure changes. An analysis was made beat by beat of the heart, measuring simultaneously mask pressure, pleural pressure, right ventricular and arterial systolic and diastolic pressures and the right ventricle net filling pressure.[19] The net filling pressure, obtained by subtracting the simultaneously measured pleural pressure from the end diastolic pressure in the right ventricle, changed generally inversely with the pleural pressure. An increase in the net filling pressure corresponded to a decrease in pleural pressure. Successive decrease and increase in net filling pressure were therefore well in phase with variations in venous return to the right heart, which follow changes in intrathoracic pressure. An increase in the net filling pressure should result, according to Starling's law, in an increase in the output from the right heart, and a decrease should result in a decrease in output. During inspiration in intermittent positive pressure breathing, the increase in pleural pressure during inspiration results in a decrease in the net filling pressure of the right ventricle and therefore in a decreased output from the right heart. During expiration the pleural pressure decreases (rapidly or slowly depending on the type of mask pressure curve produced by the respirator), and this decrease results in an increase in the net filling pressure of the right ventricle, leading to an increase in cardiac output from the right heart.

Table 8.—*Comparison of Breathing Characteristics and Changes in Cardiac Output in One Subject Studied on the Same Day with Both the Type 1 and Type 4 Respirators*

	Respirator Type	
	1	4

Cardiac output		
Liter per minute	7.21	9.87
Per cent change from output during natural breathing	—17.5	+3.7

Similar studies on the output of the right heart during normal deep breathing in man[20], have been interpreted as indicating an increase in right ventricle stroke volume during inspiration and a decrease during expiration.

In the 4 patients with pneumothorax the arterial pulse pressure curves were more or less parallel to the pleural pressure curves. In the case of M. W. (fig. 10, table 9), with a very long sustained increase in pleural pressure the arterial pulse pressure increased at first and then rapidly decreased, indicating a reduction in left heart stroke volume after a few beats. This result confirms previous studies made on sustained forceful expiration in man.[20] The latter change may be interpreted as indicating that after a short interval of time the effect of the reduction in right heart stroke volume was transmitted to the left heart, causing a diminution in left heart stroke volume and therefore a reduction in arterial pulse pressure. A similar change is shown in fig. 6*B* with type 5.

Table 9.—*Comparison of Unfavorable (A) and Favorable (B) Time Ratio for Mask Pressure on Cardiac Output with Type 4 Respirator*

	Line Pressure, Cm. Water	Ratio: Inspiration to Expiration	Cardiac Output		Mean Mask Pressure, Mm. Hg	
			L./Min.	Per Cent Decrease from Control Ambient	During Inspiration	During Expiration
A	26	3.9	3.7	39.0	16.8	3.8
B	16	0.9	6.0	1.0	7.9	2.0

The transmission of the negative phase with type 5 ("suck and blow") was very slight in the case of M. W., with a frequency of 14 cycles per minute (fig. 6*B*). The negative pressure did not result in a striking increase in right ventricle net filling pressure, and the lowest filling pressure present corresponds to the lowest

---

20. Lauson, H. D.; Bloomfield, R. A., and Cournand, A.: The Influence of Respiration on the Circulation in Man with Special Reference to Pressures in the Right Auricle, Right Ventricle, Femoral Artery and Peripheral Veins, Am. J. Med. 1: 315 (Oct.) 1946.

negative pressure of the mask. Also, the arterial pulse pressure on the same subject (M. W.) was not influenced by variations in mask pressure. No evidence was obtained that negative pressure during part of the cycle increases cardiac output. On the other hand, the "suck and blow" type respirator did not produce adverse effects on the circulation when used for one hour in 2 cases of deep coma. The negative mask pressure was transmitted much less to the pleural pressure than the positive pressure.

In summary, intermittent pressure breathing will result in the following cycle changes due to variations in intrathoracic pressure: (1) during the increasing inspiratory pressure period the venous return to the right heart diminishes; (2) during the phase of diminishing expiratory pressure the reverse takes place, and (3) the more rapid and complete the pressure drop to zero after reversal at the peak pressure, the greater the filling of the right side of the heart during expiration.

The over-all changes in cardiac output will vary with the type of pressure curve. Type 1 produces a symmetric type of curve, and the pressure drops slowly at approximately the same amount per time unit as the increase during inspiration. The time on low pressure during one complete cycle is about the same as the time on high pressure. The changes in cardiac output are more related to the height of the mean mask pressure than to the ratios between inspiration and expiration. In the case of type 4 curve the rapid initial drop of pressure in expiration (fig. 11) allows the deficit occurring during the inspiration to be partly overcome in the first few beats. The complete compensation, however, will be dependent on two factors, (*a*) the duration of the expiratory period with as many heart beats as during inspiration and (*b*) the pressure existing during this time. The expiratory mean mask pressure on type 3 is relatively higher (2.5 cm. of water as a minimum) than on type 4. Hence type 3 occupies a position between type 1 and type 4 with respect to the decrease in cardiac output. In the case of type 4 the rapid drop in pressure and the total low expiratory mean mask pressures favor compensation of the deficit occurring during the inspiratory phase of rising pressures. A high mean mask pressure with type 4 results in large decreases in cardiac output (fig. 10 *A*), but to produce a high mean mask pressure for the entire cycle (12 to 15 mm. of mercury) with type 4, a short expiration time is required, thus not permitting adequate time for compensation to occur.

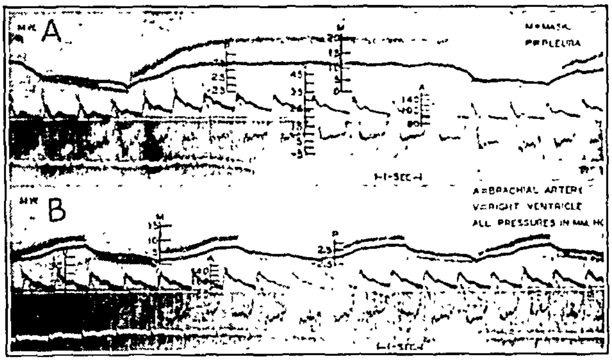

Fig. 10.—Comparison of an unfavorable (*A*) and a favorable (*B*) time ratio for mask pressure on cardiac output with the type 4 respirator (Hamilton manometer recording).

COMMENT

A. *Interpretation of the Mechanism of Action of Intermittent Pressure Breathing on the Circulation.*—It has been shown previously that in normal subjects the stroke volume of the two ventricles is unequal during deep breathing.[20] As the pressure in the thorax increases during expiration, filling of the right side of the heart from the large veins is reduced and the stroke volume diminishes; meanwhile, the output from the left side of the heart increases as a result of increased pulmonary venous return.

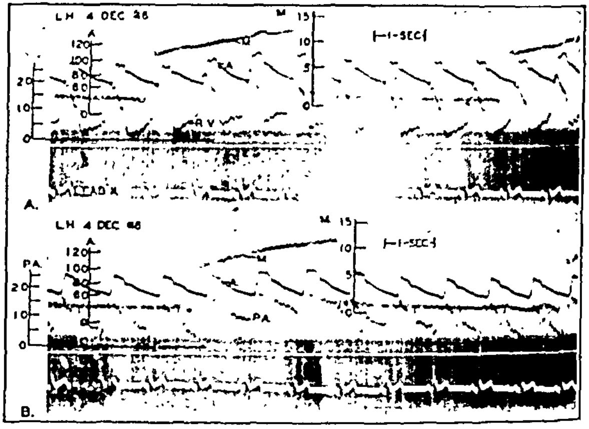

Fig. 11.—Desirable type of mask pressure curves produced by the type 4 respirator; there was no decrease in cardiac output: pressure tracings from above downward—*A*, mask, brachial artery and right ventricle; *B*, mask, brachial artery and pulmonary artery (Hamilton manometer recording).

The present study indicates that the same mechanism operates during intermittent pressure breathing in a reverse fashion and to a greater extent. The phase of rising intrathoracic pressure takes place during inspiration and the phase of decreasing pressure during expiration. The decrease in output from the right side of the heart, during the phase of rising pressure in the mask and in the thorax, is made up during the phase of falling mask pressure. For the left side of the heart the reverse occurs. However, the left side of the heart can only increase its output during inspiration for a short time (three to five beats) by ejection of blood squeezed out of the lungs. More extended increase in output of the left side of the heart will take place only after more blood has been supplied again by the right side of the heart. Thus, the variation in stroke volume of the right ventricle is the important part to consider in relation to sustained changes in cardiac output.

During intermittent pressure breathing the pressure should not only be low during expiration, but this phase of low pressure in the thorax should be of sufficient length. The total expiratory time interval should allow a sufficiently large number of heart beats to take place to compensate for the reduction in output which occurs during the inspiratory period of rising pressure. The type 1 symmetric curve (figs. 6 *C* and 3, 11 *A*) with inspiratory and expiratory time almost equal, affects the cardiac output through the entire cycle. There is positive pressure in the thorax during the whole of the respiratory cycle, which diminishes continuously the venous return of blood to the right side of the heart. The greater the increase in mean mask pressure, the larger the reduction in cardiac output with the type 1 respirator (fig. 9). The type 3 curve has a quick pressure drop on expiration, which permits the right side of the heart early in expiration to make up part of the loss incurred during inspiration, but the compensation is not complete as the pressure does not return to atmospheric and the expiratory time interval is too short. In fig. 8 there are only approximately three heart beats during expiration with type 3 to make up for the decreased output of six heart beats during inspiration.

The type 4 curve also has a quick pressure drop on expiration and thus permits an early compensation. Complete compensation occurs in those subjects using type 4 in whom the expiratory time is long enough and the expiratory pressure is allowed to drop to atmospheric (fig. 11). In patients with short expiratory time intervals the compensation is incomplete (fig. 10 *A*). The decrease in cardiac output on type 5 is insignificant, as this respirator produces a mean mask pressure that is relatively low during the positive phase and only slightly above atmospheric for the entire cycle.

B. *Ideal Type of Respirator Equipment.*—The ideal type of respirator for use on man (producing effective artificial respiration with a minimal disturbance to the circulation) should embody the following characteristics:

1. It should be simple and sturdy in construction and operation, small and compact in size, as in type 1, type 2 and type 7. The respirator apparatus should stand steam sterilization if expiration occurs through part of the device as in type 1. Expiration should not occur through the flow-sensitive respirators with reversing pistons as in type 4.

2. The mask pressure curve should increase gradually during inspiration up to a peak not in excess of approximately 25 cm. of water, and after reversal occurs the pressure drop should decrease rapidly to a final pressure near atmospheric (figs. 11 and 3, I *A* and II *C*). The mean mask pressure during the expiratory period should be as low as possible. There is no apparent advantage of including negative pressure in the cycle.

3. Alternating frequency rates should maintain a respiratory rate between 10 and 20 per minute.

4. The volumes of pulmonary ventilation provided should be on an average from 6 to 10 liters per minute.

5. A regulator line pressure should be provided that takes into account the pressure drop in transmission for the particular type of respirator used and provides peak pressures from 10 to 25 cm. of water (7.4 to 18.4 mm. of mercury).

6. The mask most suitable for use in this study has been one having a wide, inflatable, thin, soft rubber cuff built over a sponge-type cushion base and detachable from a light weight transparent plastic facepiece (fig. 2 *D*). This type of mask has provided the best leakproof fit and the least dead space.

SUMMARY AND CONCLUSION

1. In this study all the automatic respirators tested produced adequate ventilation in all types of subjects, whether conscious, comatose or apneic. The manual respirators also performed satisfactorily on the apneic subjects. The manual methods, such as the Schaefer, were inadequate in providing adequate pulmonary ventilation for any length of time in the apneic subject. (However, any sort of manual artificial respiration should be started immediately and continued until a respirator can be obtained.)

2. In administering artificial respiration in the apneic subjects either by respirator or manual methods, the position of the body that provides the minimal resistance to pulmonary ventilation was found to be: (1) hyperextension of the head on the cervical vertebrae, (2) support of the lower jaw from below and (3) the body flat or in a slight Trendelenburg position without pillows under the head. An airway tube may be used; however, in the present studies with respirators the use of such a tube did not result in a significant change in ventilation rate. An endotracheal tube with an inflatable rubber cuff on the end definitely decreases the resistance to artificial respiration in the apneic subject, and this was the most satisfactory arrangement for using type 1 on apneic subjects for long periods of time. The regulator line pressure may be set much lower (10 to 15 cm. of water) with the endotracheal tube and still maintain proper cycling of the respirator and adequate pulmonary ventilation. The falling back of the tongue with blockage of the airway has not been a problem in preventing adequate ventilation with the respirators. Excess fluids and secretions if present should be removed by suction. The proper position of the head should be secured as quickly as possible, for in administering artificial respiration with respirators this is a most critical factor in determining success or failure.

3. The apneic subject in need of artificial respiration should be given 100 per cent oxygen, preferably with the automatic respirators. Studies on the arterial blood before treatment revealed low oxygen saturation, increased carbon dioxide content and a decreased p_H. The addition of 5 per cent carbon dioxide with oxygen would only increase the acidosis.

4. No signs or symptoms of acapnia or tetany were observed even in those subjects with decided hyperventilation (over 15 liters per minute) during artificial respiration. The average changes in p_H and pCO_2 with the automatic respirators producing ventilation rates from 5 to 15 liters per minute were not enough to produce clinical signs of alkalosis.

5. The decrease in cardiac output was variable, large decreases (30 to 40 per cent) occurring in some instances and no decrease in others on line pressures necessary for adequate ventilation. This observation has been correlated with the type of the mask pressure curve present rather than with a particular respirator.

6. The automatic and manual respirators, if properly adjusted, did not produce undesirable effects on the circulation when line pressures adequate to give pulmonary ventilation in apneic subjects were used. All the respirators studied were satisfactory for use and far superior to the manual methods of resuscitation.

7. The ideal mask pressure curve should increase gradually during inspiration to a peak not higher than about 25 cm. of water. The pressure should drop rapidly after reversal, in the beginning of expiration, decreasing quickly to or near atmospheric, with a mean mask pressure during the expiratory period as near as possible to atmospheric. Inspiratory time should not exceed expiratory time.

8. The type of mask pressure curve described in the preceding paragraph permits the right side of the heart to compensate during expiration. From a detailed study of the variations in net filling pressure in the right side of the heart, evidence has been presented indicating that the stroke volume decreases during inspiration due to increased pressure in the thorax. The time and pressure during expiration should be adjusted in such a manner that the total inspiratory cardiac output deficit can be made up by a sufficient

number of heart beats in expiration having a normal or increased stroke volume.

9. Although all the respirators performed in a satisfactory manner in producing adequate artificial respiration, the following criticism may be given for the design of each type as far as concerns the shape of the mask pressure curve produced by it.

Type 1, a pressure-sensitive respirator, may be improved to give a more nearly ideal physiologic performance by a modification of the valves so that the mask pressure curve at the beginning of expiration decreases quickly to or near atmospheric, with a mean mask pressure during the expiratory phase as low as possible. The performance of this apparatus was remarkable over long periods of time; it is easy to clean and sterilize. The plastic model was unsatisfactory due to the warping of valves and the danger of breaking the outside wall.

Type 3, a flow-sensitive respirator, produced an unfavorable type of mask pressure curve because (1) the expiratory time interval is to short and (2) the minimal pressure at the end of expiration is plus 2.5 cm. of water. This instrument was designed primarily for aviation use, and the increased expiratory pressure was advantageous at high altitude; however, the short expiratory period is undesirable even at high altitude with respect to the ideal mask pressure curve based on physiologic studies in man.

Type 4, another flow-sensitive respirator with the various adjustments provided, was an ideal research instrument for studying the numerous variables involved in intermittent pressure breathing and various types of mask pressure curves in relation to changes in cardiac output. The design is complex and the operation requires constant supervision by trained personnel. However, employing the basic principle of design, flow primarily, in contrast to pressure as on type 1, satisfactory production model respirators may be made. The expiratory flow outlet on commercial models of type 4 should be separate from the main respirator mechanism so that vomitus or secretion cannot be blown in the device and jam the reversing mechanism.

Type 5, an example of the "suck and blow" type, was slightly less capable of overcoming breathing resistance in the apneic subject as compared to the intermittent positive pressure models. The negative pressure phase has not been found advantageous over simple intermittent positive pressure. However, no harmful effects were observed when the "suck and blow" was used for one hour in 2 cases of deep coma. There was no evidence in this study that the negative pressure phase aided the circulation. The mechanical performance of the device was satisfactory.

Type 2 produced a mask pressure curve similar to that of type 1, which has already been discussed. The mechanical performance of this model was satisfactory.

Type 6, a manually operated respirator, produced a fairly satisfactory mask pressure curve. The expiratory valve should open more quickly and allow the pressure to drop more rapidly to atmospheric. The sliding valve arrangement was considered unsatisfactory, because the inexperienced operator may block effective ventilation by getting his hand in the way of the sliding part.

Type 7, another manually operated respirator, gave a very desirable type of mask pressure curve. The operation of this model was smoother and safer than that of type 6.

10. In the types of intermittent positive pressure respiration produced by mouth to mouth insufflation, by applying pressure on an anesthesia rebreathing bag or by manual respirators the operator controls the time ratio of inspiration to expiration. It is extremely easy to allow a slightly longer expiratory than inspiratory time period, which permits more heart beats during expiration and allows the heart to make up for the decreased output occurring during the phase of increased pressure in the thorax.

11. Oxygen, helium and oxygen mixtures, and compressed air are too dry for prolonged use on conscious subjects (such as those who have poliomyelitis with complete respiratory paralysis) with intermittent positive pressure respirators. Some form of humidification is necessary for the dry tank compressed gases.

12. Intermittent positive pressure can be used as a means for administering artificial respiration without decreasing cardiac output when the pressure and time for inspiration and expiration are properly regulated.

SANBORN VISO-CARDIETTE ACCEPTABLE

Manufacturer: Sanborn Company, 39 Osborn Street, Cambridge 39, Mass.

The Sanborn Viso-Cardiette is a direct-writing electrocardiograph. The records appear in permanent form on plastic-coated paper. The machine requires a 110 volt, 60 cycle alternating current and consumes 70 watts. The galvanometer is connected with a stylus bearing a heated point which records data on temperature-sensitive paper. A control is provided to adjust the temperature of the point. The recordings obtained in this way are not easily marred, nor are they affected by direct sunlight. Reloading of paper is easy.

The specimen submitted to the Council office for examination was sent to a special investigator for physical tests, as well as clinical trial, in the light of the Minimum Requirements for Acceptable Electrocardiographs as published in THE JOURNAL, 134:455 (May 31) 1947

1. *Recording Mechanism.* - The investigator reported that the foregoing statements concerning the recording mechanism were accurate.

2. *Sensitivity and Adjustability.* - External voltage sources, both alternating and direct, were connected with various leads through a series resistance of 2,000 ohms, as directed in the requirements. It was shown that the response of the instrument to its incorporated standardizing signal of 1 millivolt was within a range plus or minus 5 per cent of the response to the externally applied signal, and that the test signal voltage could be maintained for a period of two or more seconds. It was noted that the maximum sensitivity was 700 microvolts per centimeter. There was a slight wandering of the stylus from its adjusted base line during normal operation due to alternating current line-voltage fluctuations.

3. *Amplitude Response at Various Frequencies.* Amplitude response recordings of direct versus alternating current signals were obtained at frequencies of 1, 2, 5, 10, 15 and 40 cycles per second, and an external signal generator was swept through frequencies from 40 to 300 cycles per second, while the stylus deflection was measured in millimeters.

4. *Decay Characteristics.* - The response of the instrument at 0.2 second after the application of a direct current of 1 millivolt was compared with the response at 0.04 second.

5. *Relation of Deflection to Voltage.* - The magnitude of the stylus deflection was measured for every step of 100 microvolts from plus 2,000 through zero to minus 2,000.

6. *Adequacy of Grounding.* - With the electrocardiograph connected as for previous tests, and with a millivolt of external direct current pulse applied to the input terminals, the sensitivity was adjusted to give a 1 cm. deflection, and a recording was obtained. The input terminals were then shorted together, and the same signal was applied between this point and the ground of the instrument. There was no response under this latter condition. Increasing the input signal to 100 millivolt gave a 0.5 mm. deflection.

7. *Timing Mechanism.* - A synchronous motor actuates a contractor and provides one second time signals; these can be recorded with any of the leads.

8. *Shock Hazard.* - Although the instrument did not carry an "Underwriters' Listed" label, there was no measurable voltage at the patient cable leads and ground at any setting of the leads-selector switch.

The firm complied with all requirements as regards advertising material and promotional methods. The Council on Physical Medicine voted to include the Sanborn Viso-Cardiette in its list of accepted devices.

DAZOR SUN-HEAT LAMP FIXTURE ACCEPTABLE

Manufacturer: Dazor Manufacturing Corp., 4481-4487 Duncan Avenue, St. Louis.

The Dazor Sun-Heat Lamp Fixture is of the pedestal-type having a circular cast iron base. Above the base there rises an upright bearing the switch box and the pivot for the floating arm bracket. The bracket consists of two arms hinged together so that the maximum reach is 61 cm. (24 inches). At the far end of the outer arm there is a reflector housing that contains a plastic heat-resistant handle for positioning. The fixture as a whole is sturdy and attractive in appearance and bears the approval of the Underwriters' Laboratories.

Bulbs are not furnished with the fixture. It is, however, especially useful in connection with R S sun bulbs drawing 275 watts on 110 to 125 volts alternating current supplies and R-40 heat bulbs drawing 250 watts on 110 to 125 volts alternating or direct current supplies. The diameter of the base is about 30 cm. (12 inches), and the whole weighs 11.3 Kg. (24 7/8 pounds); the shipping weight is 17 Kg. (37¼ pounds).

The apparatus was studied by an investigator for the Council, and was found satisfactory. The Council on Physical Medicine voted to include the Dazor Sun-Heat Lamp Fixture in its list of accepted devices.

WHIRLPOOL CARRIAGE, MODEL A, ACCEPTABLE

Manufacturer: Whirlpool Carriage, Inc., 113 East State Street, Westport, Conn.

The Whirlpool Carriage is a portable device for agitating the water in a bathtub or basin. It can be trundled alongside the tub; the casters can be either released or locked. The top of the apparatus can then be raised, rotated through an angle of 180 degrees, and lowered into the water. The stirring mechanism, as it is rotated into place over the water, will clear the brim of the tub at a height of 51 cm. (20 inches) above the floor; by tilting the base, it can be made to clear a brim of 61 cm. (24 inches) above floor level. The usual precautions must be observed to guard against shocks from the use of electric equipment near water; a ground wire is to be clipped to a good ground contact.

The motor connected to the agitator requires a 110 to 115 volt alternating current and draws 650 watts. The base of the apparatus is finished in a white-cream enamel. The total weight of the apparatus is 40.8 Kg. (90 pounds); the shipping weight is 97 Kg. (216 pounds). Its height when not in use is 64 cm. (25 inches).

When examined by an investigator for the Council, the apparatus was found to be of sturdy construction and neat appearance. Additional evidence from other sources acceptable to the Council corroborated the investigator's report of satisfactory performance. The Council on Physical Medicine voted to include the Whirlpool Carriage, Model A, in its list of accepted devices.

ALOE "HELIOGRID" COLD RAY QUARTZ LAMP ACCEPTABLE

Manufacturer: A. S. Aloe Company, Olive at Nineteenth Street, St. Louis.

The Aloe "Heliogrid" Cold Ray Quartz Lamp is a source of ultraviolet light using mercury vapor in a "body grid" composed of "84 inches (238.76 cm.) of pure fused quartz with special graded leakproof seals." This grid is mounted in a spun steel head finished in bronze and trimmed with chromium. The over-all height is 170 cm. (67 inches). The lamp is adjustable vertically and horizontally. The base, equipped with 2 inch (5.08 cm.) casters, houses the transformers. The lamp operates on 115 volts alternating current and draws 40 watts. It is equipped with a built-in timer adjustable for periods from a few seconds to five minutes.

The lamp submitted by the firm was sent to an investigator. He reported that an exposure of 60 to 75 seconds with the grid applicator at 60 cm. produced a perceptible erythema in twelve hours. The lamp is well constructed and of good appearance. The grid applicator was easily adjustable; the orificial applicator was well made and easy to manage. A rayon sleeve is provided to be used over the orificial applicator tube. The exposure guide accompanying the apparatus seemed accurate enough for general use by a physician.

Since this lamp met the erythema dose requirements established by the Council on Physical Medicine of the American Medical Association for cold quartz lamps and in view of the good construction of the lamp, the Council voted to include the Aloe "Heliogrid" Cold Ray Quartz Lamp in its list of accepted devices.

DUREX DIAPHRAGMS, INTRODUCERS AND FITTING RINGS ACCEPTABLE

Manufacturer: Durex Products, Inc., 684 Broadway, New York.

Durex Products, Inc., submitted the following devices to the Council on Physical Medicine: Deep Dome Dumas Diaphragms, Shallow Dome Diaphragms, Duraflex Diaphragms (Matrisalus), Coiled Spring Diaphragms, Mensinga Diaphragms (Flat Spring), Bow-Bend Diaphragms, Coiled Spring Measuring Rings, Individual Diaphragm Introducers and Mayer Diaphragm Introducers.

These devices were referred to an investigator specializing in gynecology for examination and report. Their construction and the evidence for their effectiveness and safety were declared satisfactory. The investigator also reported that the products satisfied the Requirements for Acceptability of Contraceptive Devices recorded in THE JOURNAL(132: 991 [Dec. 21] 1946).

The Council on Physical Medicine voted to include the Durex Diaphragms, Introducers and Fitting Rings in its list of accepted devices.

EDITORIAL ANNOUNCEMENT

The absence of the compositors from their work continues. This issue of THE JOURNAL has been prepared in part by the use of Vari-Typer machines.

RICKETTSIALPOX, A NEW RICKETTSIAL DISEASE

Reports of cases of an acute febrile disease of unusual character were first received by the New York City Department of Health toward the end of June 1946. Sussman[1] reported a recent increase of cases of a peculiar "spotted fever" disease which appeared in the housing development in Kew Gardens, Queens. The clinical appearance resembled that of typhus. The failure to cause agglutination with the usual antigens distinguished the condition from known diseases. Shankman[2] examined more than 60 patients presenting similar symptoms during the same period in the three block square area of Regency Park. The area involved was infested with mice and rats so that the possibility of a rickettsia or virus etiology was strongly suggested.

A joint study by the New York City Health Department and the United States Public Health Service of 144 nonfatal cases of this disease[3] helped to establish the disease as a definite clinical entity for which, because of some similarity to chickenpox, the name rickettsialpox was suggested. The disease is characterized by the appearance of an initial lesion about a week before the onset of fever, chills, sweats, headache and backache and by the appearance of a maculopapular and papulovesicular rash about three to four days after the onset of fever. Except for leukopenia, routine laboratory results are generally negative. The usual bacterial agglutination tests are uniformly negative; however, antibodies for rickettsialpox are demonstrable by means of the complement fixation test. There have been no deaths. Blood cultures were negative in all of the patients. Agglutination tests for typhoid bacilli, paratyphoid bacilli A and B, Brucella, Leptospira icterohaemorrhagiae, Leptospira canicola and Pasteurella tularensis were done with the serums of 30 samples of blood obtained from patients in both the acute and the convalescent stages. Agglutination tests for Proteus OX19 and OX2 were done with the serums of a considerable number of recovered patients. With the exception of a few that agglutinated in low titers, all were negative.

Huebner[4] and his associates at the National Institute of Health isolated from each of 2 patients with this disease an organism proved to be a rickettsia. This organism produced illness in mice and guinea pigs and grew well in the yolk sacs of fertile eggs. Ether-extracted yolk sac antigens were prepared which fixed complement with convalescent serums drawn from typical cases. "Cross tests" with immune serum and antigens from other species of rickettsia demonstrated that this strain is antigenically distinct from the organisms causing typhus, tsutsugamushi and Q fever. The reaction appeared to be specific except for the cross reactions with Rocky Mountain spotted fever. The behavior of the isolated organism resembled that of Rickettsia conori, the causative agent of fièvre boutonneuse, except for the failure of the disease under study to stimulate agglutinins for strains of Proteus OX 19 and OX 2 in the serums of most of the New York patients.

The basements of the dwellings in which some of the cases occurred were infested with mice and with the rodent mite Allodermanyssus sanguineus. Huebner[5] and his associates recovered a rickettsia from a saline suspension of the tissues of mites and a rickettsia which was morphologically, culturally and serologically similar from a mouse "bitten" by A. sanguineus. The behavior of the two mite strains in producing disease in guinea pigs, mice and chick embryos and as antigens in the complement fixation tests seem to establish the

as identical with the strain of rickettsialpox isolated from the patients. Further evidence of this identity has been provided by solid immunity afforded guinea pigs by rickettsialpox against one of the mite strains. Apparently identical strains of rickettsia from a man ill with rickettsialpox and from bloodsucking mites collected from the domicile of the same man indicate that human infection is acquired from the mites probably through biting. The authors suggest the name Rickettsia akari for this newly discovered microorganism of the rickettsial group.

MENTAL HOSPITALS: NEW YORK

The Committee on Public Health Relations of the New York Academy of Medicine[1] has recently reported on problems of the New York state mental hospitals system. Administrators of such hospitals face numerous problems, but they are especially concerned with provision of care for more patients than the rated capacities of their institutions. Public indifference to the fate of mental patients is still reflected by the depersonalization of care rendered in mental hospitals. Research programs connected with the mental hospital system are badly needed. The principal problems are overcrowding, understaffing, insufficient funds and deteriorated physical plants. Immediate recommendations call for correction of existing overcrowding by systematic review of patients, with discharge of patients in convalescent state or to family care. Expansion of the program of family care is desirable to secure increase in numbers of foster homes for mental patients and establishment of proper levels of payment. An effort should be made to attract competent personnel by providing adequate salaries and good living conditions. Proper investigation is necessary to obtain larger payments from relatives of patients. Repair of existing deficiencies in physical plants is necessary with advice from expert architects. Present inadequacy should be brought to the attention of the public and legislative bodies. The committee recommends long term planning to formulate a definite, integrated policy for future care. Institutional units should be limited to not more than 3,000 beds. New mental hospitals need to be located near large urban centers, so that they may affiliate with teaching institutions. Experimental hospital units for new approaches to treatment are necessary. An attempt should be made to establish sufficient numbers of psychiatric clinics to insure proper preventive outpatient care and treatment. The staffs of mental hospitals should be qualified to conduct research in the physiologic as well as psychologic factors of mental disease. Psychiatric service must provide comprehensive training programs for both young psychiatricts and general interns and special provision should be made for graduate training of psychiatric nurses, social workers, clinical psychologists and other needed auxiliary personnel. Finally, the public should be thoroughly enlightened concerning mental illness, its prevention and the needed facilities for treatment.

The committee report on conditions and needs in the mental health field of New York state mirrors completely conditions and needs in mental health throughout the United States.[2] Mental health is outstandingly a leading medical, public health and social problem.

Throughout the nation funds are insufficient for improvement of physical plants, increased facilities for training of personnel and increased research. Present knowledge offers the greatest hope for improvement of mental health in the United States by a concerted attack in the preventive field. Goals have been set which demand availability of at least one mental hygiene clinic per hundred thousand population. While this goal has by no means been reached today, the immensity of the problem would in all likelihood still make it insufficient. The need is certain to be increased once a properly educated public is relieved of its tendency to avoid obtaining psychiatric aid even when they themselves recognize the need.

No other field of health is as greatly handicapped by social stigma as is mental ill health. This handicap will be diminished and real needs supplied only by a greatly intensified program of public education wherein responsibilities are made known and the implications of personal and collective social attitudes in determining mental ill health are made clear

Current Comment

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

Physicians who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect registration on or before July 1 to avoid a penalty. Each year, despite the annual warnings in THE JOURNAL, this requirement is overlooked by some physicians and unpleasant consequences follow. Failure to register adds a penalty of 25 per cent to the tax payable and in addition subjects the physician to the possibility of a fine not exceeding $2,000 or to imprisonment for not exceeding five years, or to both. As an act of grace the Commissioner of Internal Revenue has in past years given some tardy registrants the choice between paying sums by way of compromise, a procedure authorized by law, or accepting criminal prosecution. If this procedure does not produce the required promptness in reregistration, the commissioner will have no other alternative than to institute criminal prosecution.

WHICH KENNETH WALKER WILL YOU HEAR?

About a year ago THE JOURNAL received a complaint from England that misrepresentations were occurring with respect to the identity of an American lecturer named Kenneth Walker. A distinguished Fellow of the Royal College of Surgeons has the same name. Contact was made with the American lecturer; he wrote that only recently had he become aware of the identity of the English surgeon and he asserted that the misrepresentation in promotional material being used by a booking agency in his behalf had come about rather innocently. The American lecturer had left a copy of a book written by the English physician in an office where an unnamed employee had accidentally seen it and assumed at once that the American was the author. Distribution of the erroneous piece of promotional literature, according to the American Kenneth Walker, had been stopped. Now Dr. Kenneth Walker of London, author of the well known book, "Physiology of Sex," has again indicated that there is persistent reliance on the similarity of the names by the American lecturer. The American Kenneth Walker has appeared before many gatherings during the past season, using as a subject " Live Together or Live Not." The impression is apparently prevalent that the American, who lectures on personal experiences and observations in foreign countries during the World War just ended, is the eminent English surgeon. A man has exclusive right to his reputation. When his name is the same as that of another man, confusion of repute should be avoided. Abuse of the similarity in names is not only undesirable but unethical and may be damaging. Since the British Kenneth Walker is an eminent physician and the American is not, confusion as to the identity might be especially reprehensible.

AMINO ACID AND VITAMIN INTERRELATIONS

Recent experimental observations on the production of deficiency complexes and their therapeutic control by varying the quantitative and qualitative dietary intake of amino acids and vitamins may have distinct implications as to the etiology and treatment of certain conditions of disease in man. The first observation suggestive of an interrelation between the activity of vitamins and amino acids was provided by Goldberger, who noted that the amino acids tryptophane and cystine exert some beneficial effect in human pellagra, indicating that factors in addition to nicotinic acid may be involved in the production of this disease. Subsequent observations showed that blacktongue, the canine counterpart of pellagra in man, produced by feeding corn grits and a synthetic diet low in nicotinic acid, as well as the growth inhibition in rats under the same diet, can be counteracted by adding tryptophane alone to the diet.[1] Bessey and Wolbach[2] found that in rats on a diet deficient in lysine or tryptophane there developed corneal vascularization similar to that in animals with riboflavin deficiency. Maun, Cahill and Davis[3] reported similar ocular lesions in rats on a diet deficient in leucine. Hueper[4] observed the development of porphyrin incrustations on the snout and ears of rats on a diet low in protein and methionine and deficient in aromatic amino acids (gelatin). These conditions, usually found in certain vitamin deficiencies (riboflavin, pantothenic acid), were not obviated when large amounts of these vitamins were added to the diet. The inhibition of growth exerted on cultures of Streptococcus lactis by excessive amounts of glycine or serine in the medium as well as the toxic effects elicited in animals given abnormal quantities of these amino acids can be prevented by pyridoxine.[5] Daft[6] recently recorded that rats made agranulocytic by feeding a protein-free diet gave granulocytic response when given folic acid; he noted that this action was accentuated when nicotinic acid, methionine and threonine were added. While the granulocytic reaction to the vitamins was rapid, it was slow if the agranulocytic rats were given a mixture of essential amino acids. There appears to be a relationship between amino acid and vitamin deficiencies and the development of blood dyscrasias. The experiments of Wissler and associates[7] revealed that the repletion of protein and the formation of antibodies in protein-depleted adult rats is impaired when these animals are fed a ration adequate in high quality protein but deficient in certain vitamins. It is not likely that the action of the amino acids is due to a direct replacement of vitamins. An adequate supply of suitable amino acids seems to enable the animal organism or its intestinal flora to synthesize vitamins of the proper type. The utilization of vitamins by the organism, on the other hand, seems to be defective unless adequate amounts of amino acids of the proper type are available. Since radical changes in the kind of intestinal bacterial flora and thereby in the quantitative and qualitative production of vitamins by these micro-organisms can be brought about by dietary changes, control of the resultant manifestations of deficiency may be accomplished in certain conditions by varying the quantitative and qualitative intake of proteins. The various observations on the interrelations between the action of amino acids and vitamins may find some practical application in human medicine in connection with the treatment of starvation states, the use of specific amino acid therapy and the causation and control of chemical blood dyscrasias, especially those of the agranulocytic variety.

Report Stresses Progress In Medical Care

A report prepared by Dr. George W. Bachman and Dr. Lewis Meriam for the private Brookings Institution, on behalf of the Senater Subcommittee on Health of the Labor Committee, observes that the United States had made great progress in health conditions. It points out that forty years ago the United States was outclassed by leading nations, while today the health of the white population is better than that of larger western European nations. It is on a par with the small nations with the best records. Health of Negroes is less favorable because of economic and social reasons, rather than lack of medical care. The report also states that there are not enough physicians to meet demands of a compulsory health insurance system.

Further Delay In Clearing World Health Bill

Although the House Republican Steering Committee had cleared legislation to permit the United States to join the World Health Organization, further delay was encountered in getting this bill out of the Rules Committee. The Republican Committee checked major legislation in advance of the scheduled June 19 adjournment and included the measure among bills slated for action this week. The Senate passed the W.H.O. bill unanimously last year and the House Foreign Affairs Committee approved it unanimously, but the Rules Committee blocked action on it. This barred the United States from charter membership in the World Health Organization and presented a strong propaganda weapon to forces opposing the democratic system of government. The State Department is in favor of congressional action so that the United States can take part in the meeting of the World Health Organization in Geneva, Switzerland, in June.

Delegates Make Capital A Medical United Nations

The two thousand delegates from all over the world to the fourth International Congresses on Tropical Medicine and Malaria gave the national capital the semblance of a medical United Nations. Sessions were conducted in English, French and Spanish, and local hotels had delegates registered from around the globe. The federal government sponsored the conference through the State Department and six other agencies, with the cooperation of fifteen national professional societies and several intergovernmental agencies. A total of one hundred and fifty societies and sixty governments received invitations, and one hundred and eighty papers from outstanding scientists of thirty seven nations were read. The scientific program was conducted in twelve sections, with as many as four meetings being held simultaneously.

U. S. Public Health Service Appointments

Surgeon General Leonard A. Scheele of the U.S. Public Health Service announced the appointment of the new deputy chief, Dr. W. Palmer Dearing of Chevy Chase, Md., and other division heads. Dr. Dearing is deputy Surgeon General and as second in command will serve as Surgeon General in Dr. Scheele's absence. He succeeds Dr. James A. Crabtree, who will direct medical mobilization planning for the National Security Resources Board. Dr. Bruce D. Forsyth was named assistant surgeon general and chief of the Dental Division, succeeding Dr. William Wright Jr., who has been transferred to duty with the Bureau of Employes Compensation, Federal Security Agency, and the Bureau of Indian Affairs, Department of Interior. Dr. Eugene A. Gillis succeeds Dr. Dearing as head of the service's Division of Commissioned Officers. He has been assistant chief. The appointments became effective May 17.

National Nutritional Yardstick Lowered By Council

The National Research Council reported at its conference here that the national nutrition yardstick has been reduced by the food and nutrition board. The daily calory allowances for sedentary persons has been dropped 100 calories below previous recommendations, with the claim that the original figure had been shown by studies since 1941 to be higher than persons actually need. The previous limit was said to be likely to cause too great an increase in weight for good health.

Amputees Win Awards For Testing Artificial Limbs

Robert S. Allen, newsman who served overseas as press chief for the late General George S. Patton Jr., was one of fifteen amputees who have been honored by the Army for " outstanding and patriotic service in testing artificial limbs and furthering the general program of research and development in the field of prosthetics." Secretary of the Army Kenneth C. Royall presented the certificates to three recipients in Washington, D. C., and army commanders in other areas were to make similar presentations to twelve others. Mr. Allen is consultant to the Committee on Artificial Limbs and cooperates with the Army Prosthetic Research Laboratory, the Mare Island Naval Hospital limb shop and Northrop Aircraft, Inc., in the development of artificial limbs and devices.

Medical Legislation

Michigan

Bill Enacted.—H. 14-XXX has become public act 14 of the Acts of 1949. It amends the hospital survey and construction act by providing that any hospital receiving federal aid under the federal hospital survey and construction act shall comply with the minimum standards of maintenance and operation which the state department of public health with the advice of the advisory hospital council shall promulgate.

Rhode Island

Bills Enacted.—H. 604 was approved April 30, 1948. It requires the enrichment of bread and flour by the addition of certain vitamins and minerals for the better protection of the public health. H. 658 was approved April 30. It provides for an act to extend and strengthen the mental health services in the state and designates the state department of social welfare as the agency to cooperate with the federal government in this regard. H. 743 was approved April 30, 1948. It provides for the licensing, regulation, inspecting and examination of homes for the aged or convalescent persons.

South Carolina

Bill Enacted.—H. 1214 has become Govenor's Act 1156 of the Acts of 1948. It puts sulfanilamide, sulfapyridine, sulfadiazine, aminopyrine, thyroid and other antifat preparations, together with any other drugs declared to be " dangerous drugs," on a prescription basis.

GOVERNMENT SERVICES

ARMY

MEETING OF CONSULTANTS

The Advisory Council of the Society of United States Medical Consultants in World War II met in the Surgeon General's Office May 8 to discuss future planning related to medical department personnel, revision of tables of organization, a new system of unit mobilization, problems of training and education and plans for medical reserve officers. Among those present were: Drs. Frank B. Berry, president; Henry M. Thomas Jr.; M. Ralph Kaufman; Alfred R. Shands Jr.; M. Barnes Woodhall; Donald M. Pillsbury; Yale Kneeland Jr.; Walter Bauer; Perrin H. Long; Ivan C. Berlien; I. Ridgeway Trimble; Francis R. Dieuaide; I. S. Ravdin; Harold A. Sofield; John V. Ambler, and Henry W. Brosin.

NEW VENEREAL DISEASE CONTROL FILM

More than one thousand four hundred educators and members of the clergy from the District of Columbia, Maryland and Virginia were invited to see March 10 the Army's new training film on veneral disease control, "Miracle of Living." The film, which is the only one currently in use for this purpose, emphasizes the moral approach to anti-venereal disease hygiene. The group was addressed by Kenneth C. Royall, Secretary of the Army, Major Gen. Raymond W. Bliss, the surgeon general, and Major Gen. Luther D. Miller, chief of chaplins. Lieut. General Willard S. Paul, director of personnel and administration, department of the Army, and president of the Army Venereal Disease Control Council, presided. A discussion was conducted after exhibition of the film, thus typifying the Army's policy of seeking civilian counsel and participation in the formulation of policies in moral and educational matters.

AWARDS AND COMMENDATIONS

Captain Harold F. Rheinlander

Capt. Harold F. Rheinlander, M.C., A.U.S., of Washburn, Maine, has been awarded the Army Commendation Ribbon for meritorious service for the period April 1946 to March 1948 as assistant chief of surgical service and then chief of surgical service, Regional and Station Hospital, Maxwell Air Force Base, Montgomery, Ala. Dr. Rheinlander graduated from Harvard Medical School, Boston, in 1944 and entered military service in April 1946.

Captain John C. Jarrett

Capt. John C. Jarrett, M.C., A.U.S., of Ellwood City, Pa., has been awarded the Army Commendation Ribbon for meritorious service for the period April 1946 to March 1948 as chief of obstetrical and gynecology service, Regional and Station Hospital, Maxwell Air Force Base, Montgomery, Ala. Dr. Jarrett graduated from Western Reserve University School of Medicine, Cleveland, in 1945 and entered military service in April 1946.

Captain Edmund D. Pellegrino

Capt. Edmund D. Pellegrino, M.C., A.U.S., of Brooklyn, has been awarded the Army Commendation Ribbon for meritorious service for the period April 1946 to March 1948 as assistant chief and then chief of medical service, Regional and Station Hospital, Maxwell Air Force Base, Montgomery, Ala. Dr. Pellegrino graduated from the New York University College of Medicine, New York, in 1944 and entered military service in April 1946.

AIR FORCE

AVIATION PHYSIOLOGISTS

Seventeen medical corps officers graduated April 16 from the aviation physiologists' course at the School of Aviation Medicine, Randolph Field, Texas Among the graduates were Lieut. Col. Francisco Sureda and Second Lieut. Amilcar Augusto, Air Force of Uruguay, Capt. George Cantoni, Air Force of France, and Lieut. Hilmi Dinc, Air Force of Turkey. The course is offered to medical officers who complete the aviation medical examiners' course. It prepares graduates to indoctrinate flying personnel on the changes in body functions at high speed and altitude. Counteraction, prevention and treatment of these physiologic changes form a major part of the instruction given to students. Col. Don Flickenger, Medical Corps, director of medical sciences, addressed the graduating class.

PROMOTIONS

John M. Hargreaves, deputy air surgeon, has received a temporary promotion to brigadier general in the medical corps of the Army. General Hargreaves, a native of Illinois and a graduate of the University of Minnesota Medical School, entered the service in 1925 and after graduating with honors from the School of Aviation Medicine in the following year was attached to the Air Forces, in which he has served since. He is also an honor graduate of the Army Medical School, a graduate of the Medical Field Service School and the Command and General Staff School. General Hargreaves was chief surgeon of the 8th Air Force on Okinawa during the recent war and later surgeon of the Pacific Air Command with headquarters at Manila and later at Tokyo.

Col. Harry G. Armstrong, commandant, Air University School of Aviation Medicine, Randolph Field, Texas, has been promoted to the rank of brigadier general. General Armstrong graduated at the University of Louisville School of Medicine and entered the Army in 1929. During World War II he was surgeon of the 8th Air Force in the European theater of operations and also surgeon, Armed Forces Division, Office of Military Government (United States) Berlin, Germany. His "Principles and Practice of Aviation Medicine" is a standard textbook throughout the world. In recognition of his work he has received the Collier Trophy and the John Jeffries award and has been decorated by England, France, Belgium and Poland.

BORDER HEALTH ASSOCIATION

Recently the United States Mexico-Border Health Association held a conference at Laredo, Texas, and Nueva Laredo, Mexico. Lieut. Col. Kenneth E.

Pletcher, M.C., from the School of Aviation Medicine, Randolph Field, Texas, was among the speakers. Following the conference, Dr. David Glusker, México, D.F., and Lieut. Col. Patricio Y. Funtes, commandant of the Indoctrination Center, Army of Mexico, visited Randolph Field and the Preventive Medicine Department and its allied research unit at the School of Aviation Medicine.

SCHOOL OF AVIATION MEDICINE

Dr. Gunnar Lundin of Sweden and Dr. Vogt Lorentzen of Norway, Scandinavian aviation physiologists, visited the School of Aviation Medicine, Randolph Field, Texas, to study laboratory procedures in aviation medicine. Sweden is in process of establishing a School of Aviation Medicine on the basis of the requirements at the Air University School of Aviation Medicine at Randolph Field.

AWARDS AND COMMENDATIONS

Major Cortez F. Enloe Jr.

Major Cortez F. Enloe Jr., now of Manhasset, Long Island, N. Y., has been awarded the Air Medal. The citation reads as follows: For meritorious achievement while participating in aerial flight in the China-Burma-India Theatre from February 1944 to May 1944. As Flight Surgeon with the First Air Commando Force, Major Enloe contributed to the success of combat operations and the aerial evacuation of wounded from behind enemy lines. The exceptional courage, professional skill and devotion to duty exhibited by Major Enloe while engaged in missions of unusual hazard reflected great credit on himself and the Army Air Force.

Dr. Enloe graduated from Friedrich Wilhelms Universität Medizinische Fakultät, Berlin, Germany, in 1937 and entered the military service of the United States in September 1942.

NAVY

RESEARCH ON TROPICAL DISEASES

The Naval Medical Research Unit, which is a part of the University of California's African Expedition, arrived in Africa in February to begin a year's study of tropical diseases. It traveled through the agricultural areas of Egypt, the Libyan Desert and the Assuan Mountains. A Bedouin guide led the party through the unbroken terrain of the desert and mountains. On reaching Wadi Halfa the Company ferried the equipment to the east bank of the Nile and opened the first temporary research laboratory in a government rest house. The Nubian Desert from Wadi Halfa to Abu Hamed was worked for zoologic as well as medical specimens. Fox, jackal, hyena, gazelle, reptiles and small game abound in this area; the only birds noted were white vultures and black ravens. In considering human diseases found in the Nubian area, Commander J. M. Amberson, MC, Commandant, reports they are similar to those normally occurring in persons of the temperate zones. Malaria, bilharzia, and trachoma are prevalent. Rheumatism, arthritis and diabetes are frequently found among the Nubians. Tropical diseases are found in the Northern Sudan. At Wadi Halfa and Abu Hamed portable x-ray machines were set up, giving the natives their first experience with x-ray. Through this project numerous diagnoses were made of fractures, renal stones, arthritic changes, pleural effusions, tuberculosis, enlarged hearts and osteomyelitis. The inhabitants of the Nubian area were examined by the medical officers to get a cross section of the diseases found there. Asthma is prevalent and found to be caused by hordes of chironomid flies. Another pest, the black fly (Simulium damnosum) attacked the group every afternoon, and its bite caused profuse bleeding. Though not a disease transmitter at Abu Hamed, this fly is infected at Dongola and in the southern Sudan, and in some areas it causes epidemic blindness.

The Naval Medical Reserve Unit now in the Anglo-Egyptian Sudan has trapped eight living shrews, some of them infected with malaria. The shrew, a mouselike creature, rare in captivity, was reported in 1913 to be infected with an undefined type of malaria, and the present report confirms this. These shrews will be sent to Washington, D. C., and placed in the care of the director of the National Zoological Park and of Dr. Clay Huff of the parasitology Department, Naval Medical Research Institute, Bethesda, Md. The Navy considers that the capture of these animals may prove of great importance in the evaluation of new chemical drugs having possible curative action on malaria.

NEW REGULAR OFFICERS

The following lieutenants (junior grade) have transferred from the Medical Corps Reserve to the Regular Navy Medical Corps: William L. Chapman, Warren, Pa.; Charles R. Sullivan, St. Petersburg, Fla., and Gilbert A. Webb, Oakland, Calif. All are graduates of the Navy's V-12 program.

The following physicians from civil life have accepted temporary appointments in the Regular Navy Medical Corps: Lieut. (jg) John J. Flahive, Springfield, Mass., and Lieut. (jg) Roy S. Ogren, Palo Alto, Calif.

Lieut. Carl E. Pruett of Kinmundy, Ill., U.S.N.R., has been nominated for active duty pending his acceptance of appointment in the Medical Corps of the Regular Navy.

Comdr. John J. Brown of Bellerose, N.Y., U.S.N.R., has accepted appointment in the regular Navy Medical corps.

Lieuts. (jg) William R. Thomas of Akron, Ohio, and Robert R. Sexton of Ipave, Ill., both graduates of the Navy's V-12 program, have accepted appointments in the regular Navy Medical Corps.

OFFICERS APPROVED FOR GRADUATE TRAINING

At a meeting in April of the Advisory Board to the Bureau of Medicine and Surgery, the following Navy Medical Officers were approved for graduate training:

Comdrs. E. E. Hogan of Oxford, N. Y., and R. R. Rambo of South Bend, Ind., to continue law course at the George Washington University School of Law.

Comdr. Harold A. Streit of Algona, Iowa, fellowship in orthopedic surgery at the Cleveland Clinic.

Comdr. John S. Thiemeyer Jr. of Norfolk, Va., extension of present course in Children's Orthopedics at the Children's Hospital, Boston.

Comdr. Joseph L. Yon of Charlottsville, Va., residency in surgery, Naval Hospital, Great Lakes, Ill.

Lieut. Howard W. Hill of Oakland, Calif., residency in surgery, Naval Hospital, Oakland.

Lieut. Jack S. May of Hyattsville, Md., to continue law course at Catholic University of America, School of Law.

SOCIETY NEWS

Rear Admiral H. Lamont Pugh (MC), assistant chief of the Bureau of Medicine and Surgery, addressed the section on General practice of medicine of the District of Columbia Medical Society, Washington, D.C., on the "The Role of the General Practitioner in Modern Medicine."

VETERANS ADMINISTRATION

HOME TOWN MEDICAL CARE FOR VETERANS

Dr. Paul B. Magnuson, chief medical director, Veterans Administration, writes: "It has come to my attention that considerable misunderstanding has developed throughout the medical profession concerning the establishment of fees for medical services to be paid private physicians participating in the so-called "Home Town Medical Care Program for Veterans." It has been contended that the Veterans Administration has arbitrarily established a fee schedule which represents the maximum amount which may be paid for any given service and which is, in effect, a national fee schedule. It has also been contended that the various state medical societies and other interested groups were not consulted when this fee schedule was adopted.

"In order to clear up any misunderstanding regarding this matter, it is desired to emphasize that my predecessor, Dr. Paul R. Hawley, had no intention at any time of establishing a national schedule of fees, nor do I contemplate doing so. However, the fee schedules originally submitted by the various state medical societies, when the "Home Town Medical Care Program" was inaugurated, varied so widely in format, terminology and fees for similar or identical services that it was deemed advisable to establish a uniform fee schedule format and to set up tentative fees which could be used as a guide by the various state medical societies when submitting their proposals for the furnishing of medical care to veterans.

"This uniform fee schedule format was formulated by the Professional Group of National Consultants to the Chief Medical Director. This group, representing the various specialties in medicine and surgery, is composed of eminent physicians from all parts of the country. Tentative fees were set up in the format after a careful analysis of prepaid medical care plan workmen's compensation and insurance fee schedules, and also the fee schedules in effect in the various states having agreements with the Veterans Administration. As was to be expected, considerable variation occurred in the fee schedules reviewed.

"The Professional Group of National Consultants made every effort to arrive at fees that were considered to be within reasonable limits and which would, as nearly as possible, allow a uniform provisional fee schedule for use as a guide in facilitating and expediting the preparation of agreements between state medical societies and the Veterans Administration.

"Further attempt was made to provide for elasticity in the charges for certain operations or other services which seemed to evoke more than average contention by listing the minimum and maximum amounts considered equitable. These items bear the notation "AA," which indicates that the fee for the given service is to be determined by arbitration and agreement between the Veterans Administration and the medical society concerned.

May I reiterate that the Veterans Administration Fee Schedule Format is in no sense to be construed as an arbitrary or national fee schedule. Furthermore, it is subject to periodic review and such modification as conditions may indicate."

VETERAN TRAINING FOR A MEDICAL CAREER

The Veterans Administration announced May 17 that one in every twenty-five World War II veterans training under the G. I. Bill is preparing for a career in medicine or a related field. Of former service men and women, 191,337 were enrolled in educational institutions in training for medical positions ranging from laboratory technicians to surgeons. Of these, 25,293 were enrolled in medical schools and 18,265 were in premedical training; 13,245 veterans were training to become pharmacists and 5,194 to become laboratory technicians and assistants.

Veterans are eligible for educational training benefits if they served in the armed forces between September 16, 1940 and July 25, 1945, had ninety days or more of active service and were released under conditions other than dishonorable.

PUBLIC HEALTH SERVICE

THREE NEW MAJOR GENERALS

The rank of major general has been conferred on three Bureau chiefs of the Public Health Service, according to Oscar R. Ewing, Federal Security Administrator. Elevated in rank from brigadier general were Dr. R. C. Williams, chief, Bureau of Medical Services; Dr. C. L. Williams, chief, Bureau of State Services, and Dr. R. E. Dyer, director, National Institute of Health. The action was under authority of Public Law 425 (S. 1454), passed February 28 by the Eightieth Congress, which amended Public Law 410, Seventy-Eighth Congress, the 'Public Health Service Act."

INCREASE IN RESIDENT PATIENTS

At the end of 1946, 382.4 of every 100,000 persons in the civilian population of continental United States were in hospitals for the prolonged care of psychiatric patients, according to figures of the Mental Hygiene Division of the Public Health Service, released April 21 by the Federal security Administrator. The number of resident patients increased during the year by 10,575, representing about 2 per cent of the 518,672 present at the beginning of the year. The number of first admissions to prolonged care hospitals during 1946 was 153,025. The figures are based on results of the 1946 Census of Patients in Mental Institutions, collected by the Bureau of the Census. Collection of these data was made a function of the Mental Hygiene Division of the U. S. Public Health Service in February of this year. The statistics, which cover either the calendar year or the fiscal year ending in the calendar year, are for hospitals which provide care for chronic patients although also receiving patients for short periods of time for observation and diagnosis. The statistics on veterans' hospitals are adjusted figures based on tabulations prepared by the Veterans Administration and cover veteran neuropsychiatric patients under the care of the Veterans Administration in federal hospitals of all types. While the figures for state hospitals and for veteran neuropsychiatric patients are substantially complete, reports were not received from an appreciable number of county and private mental hospitals. The over-all coverage, in terms of admissions, is estimated to be between 90 and 95 per cent complete.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

State Medical Election.—At the California Medical Association meeting in San Francisco April 11-14, Dr. R. Stanley Kneeshaw, San Jose, was chosen president-elect and Dr. E. Vincent Askey, Los Angeles, was installed as president.

Establish Section of Allergy.—An Allergy Section of the California Medical Association, to be known as the California Society of Allergy, was organized April 11 by thirty allergists of the state in San Francisco. Dr. Willard S. Small, Pasadena, was elected temporary chairman and Dr. Frank G. Crandall Jr., Los Angeles, temporary secretary. The new section will hold meetings in conjunction with the annual meetings of the California Medical Association. Physicians interested in allergy are invited to attend.

CONNECTICUT

Ferris Lecture.—The eleventh Harry Burr Ferris Memorial Lecture of the Yale Medical Society was given by Melvin H. Knisely, Ph.D., Chicago, May 12, on "Sludged Blood."

Personal.—Dr. John F. Fulton, chairman, Yale University School of Medicine department of physiology, will deliver the William Withering Memorial Lectures at the University of Birmingham, England, June 7-10 on frontal lobotomy. He will also receive the honorary doctor of science degree from the University of Birmingham on July 3. The Withering lectures were established in honor of the graduate of the school who discovered the action of digitalis in 1785.

COLORADO

Lectureship in Surgery.—An annual lectureship in surgery for the University of Colorado Medical School has been established by Dr. Oscar T. Clagett, 1933 alumnus, now chief of the section on thoracic surgery at the Mayo Clinic, Rochester, Minn. The first lecturer will be Dr. Owen H. Wangensteen, professor of surgery at the University of Minnesota.

Postoperative Care of Cancer Patients.—Sands House, Denver, formerly operated for the care of tuberculous women, reopened on March 22 to care for victims of cancer in the Rocky Mountain region. It will accommodate 48 patients in its two wards and twenty private and semiprivate rooms. Operated as a nonprofit association with a staff of twenty members, it is open to men and women patients of all ages on referral by a member of the Colorado State Medical Society. Postoperative care will be provided patients who are unable to secure it in hospitals and private homes.

ILLINOIS

Play Day.—The Champaign County Medical Society is making plans for their "Play Day" on June 10, an afternoon and evening affair to which all physicians in the surrounding counties are invited. There will be golf and other games in the afternoon and a nonscientific dinner in the evening.

Postgraduate Conference.—The Postgraduate Education Committee of the state medical society will hold a postgraduate conference at the Mineral Springs Hotel, Alton, June 3. The session will open with a luncheon sponsored by the Madison County Medical Society. Physicians participating in the program are: Wayne W. Flora, Chicago, anal fissure and fistula; Joseph N. Rappaport, Evanston, behavior problems of early childhood; Philip Thorek, Chicago, preoperative and postoperative therapy; Claude N. Lambert, Chicago, principles of fracture treatment, Walter F. Dillon, Chicago, cancer of the cervix and endometrium; Robert S. Berghoff, Chicago, coronary disease; Thomas D. Masters, Springfield, management of diabetes during pregnancy; Frederick H. Falls, Chicago, antepartum hemorrhage, and Percy E. Hopkins, Chicago, president, state medical society, Illinois prepayment medical care plan. Dr. Harold M. Camp, Monmouth, secretary of the state society, will speak at the banquet on "Necessity for a Cooperative Program in Providing Medical Care."

Chicago

Dr. Phemister Awarded Honorary Fellowship.—Dr. Dallas B. Phemister, chairman and professor of the department of surgery, University of Chicago, was recently awarded the honorary fellowship of the Royal College of Surgeons of England for outstanding contributions to the pathology of surgical shock and lesions of the bones and joints.

Research on Nucleic Acids.—The American Cancer Society, Inc., has awarded a grant of $18,935 to the department of pathology of the University of Illinois College of Medicine for an investigation of nucleic acids and amino acids in relation to cellular growth. Dr. Isidore Gersh, associate professor of pathology, will serve as the principal investigator.

Cancer Research Hospital.— Construction of the University of Chicago's new cancer research hospital, adjoining the west wing of the University Clinics, was started May 3. The estimated cost will be $2,000,000. The major part of the seven story building will consist of laboratories and facilities for research. Two floors will provide fifty-two beds for patients; another floor will be devoted to outpatients.

KANSAS

Premarital Examinations Lower Marriage Rate.—The Kansas State Board of Health reports that Kansas experienced a 45 per cent drop in the marriage rate for 1947 as compared to 1946, most of which must be attributed to the decrease in marriages following the new marriage laws effective in July 1947. There were only 1,799 marriages recorded in December 1947 as compared with 5,891 for December of the previous year.

MAINE

Cancer Laboratory Fund.—A committee under the chairmanship of J. Anthony Probst, New York, has been organized to raise $1,500,000 for reconstruction and maintenance for five years of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, that was destroyed last October by forest fires. Dr. Clarence C. Little is chairman of the board of trustees of the laboratory.

MARYLAND

Mental Hygiene Department Established.—A Division of Mental Hygiene has been functioning within the Maryland State Department of Health since January 7. Clinics are being held in seven counties, and plans are under way to establish services in two additional counties. This psychiatric program has been made possible through federal funds allotted to Maryland through the U. S. Public Health Service. The Public Health Service also assigned Dr. Kenneth B. Jones to this state as chief of the

Division of Mental Hygiene. Clinics provide services to all age groups in areas where no other psychiatric diagnosis or treatment is available. Patients are referred by courts, schools, welfare organizations, social service agencies, children's agencies, health officers and private physicians. Persons who come of their own accord because they recognize their needs are also accepted. In addition to the regular part time clinics held in cooperation with the county health departments, there is a full time, all purpose clinic established in Prince Georges County by the U. S. Public Health Service.

MICHIGAN

Annual Galen Lecture.—The 1948 annual lecture arranged by the Galen's Honorary Medical Society at the University of Michigan Medical School, Ann Arbor, was recently delivered by Dr. Stephen Rothman, professor of dermatology and syphilology, University of Chicago School of Medicine, on "Reactions of the Skin to Sunlight and Methods of Protection with Particular Reference to Para-Aminobenzoic Acid." Dr. Rothman spent one week at the university as visiting professor.

Final Checks from Kellogg Foundation.—The W. K. Kellogg Foundation is completing the plan on public health programs that it has underwritten since the early thirties in Allegan, Barry, Branch, Calhoun, Eaton, Hillsdale and Van Buren counties. Withdrawal has been spread over five years. Payments total $52,683.94 and bring to $2,455,091.27 the amount contributed by the foundation to establish and support local health departments. This support was part of the broad foundation program referred to as the Michigan Community Health Project. Field training programs for physicians, dentists, public health engineers, health educators and students in other fields will continue according to a second five year plan developed in 1947. A total of 1,384 persons have had field training experience in the seven counties in the training program to which the foundation has contributed $315,000 since 1933.

MINNESOTA

Johnston Lecture.—David P. C. Lloyd, Ph.D., Rockefeller Institute for Medical Research, New York, delivered the fourth annual John B. Johnston Lecture at the University of Minnesota Medical School, Minneapolis, May 19, on "Monosynaptic Reflexes and the Myostatic Unit." The lectures were established at the university in honor of the former dean of the college of science, literature and the arts, who died in 1939.

NEBRASKA

Memorial to Dr. Conlin.—At the annual meeting of the West Central Diabetes Association on March 16 a resolution was passed to establish a memorial award for the late Dr. Frank Conlin, its founder and first president. The award will be given annually for achievement in the field of diabetes. New officers elected at this meeting are all Omaha physicians: Morris Margolin, president: Charles R. Hankins, secretary, and Michael Crofoot, treasurer.

NEW MEXICO

Cancer Refresher Course.—One hundred and nineteen registrants, representing four states, were among the physicians and trained laymen who attended the refresher course on the diagnosis and treatment of cancer in Santa Fe April 15, sponsored by the New Mexico Division of the American Cancer Society, the Santa Fe County Medical Society and the Santa Fe Clinic, Inc. Among the speakers were: Drs. Roscoe R. Spencer, U.S. Public Health Service, Bethesda, Md.; Maurice N. Richter, New York, Herbert Willy Meyer, New York; Juan A. del Regato, Columbia, Mo., and Philip Rosenblum, Chicago.

Annual Meeting of State Medical Society.—The New Mexico Medical Society will hold its annual meeting at the Elks Club, Los Vegas, June 3-5 under the presidency of Dr. Victor K. Adams, Raton. Out of state speakers will be:

Jacob A. Bargen, Rochester, Minn., Management of Lesions of the Small Intestine.
Charles E. Shannon, Chicago, Injuries of the Head.
Morris Fishbein, Chicago, Editor, THE JOURNAL, Trends in Medical Legislation.
Fred Shapiro, Chicago, Intracapsular and Extracapsular Fractures of the Hip.
Earl E. Ewert, Boston, Treatment of Cancer of the Bladder.
Arnold D. Tuttle, Chicago, Comfort Aloft.
William T. Carlisle, Chicago, Forewarning and Forearming in Obstetrics.
John A. Lichty, Denver, Rheumatic Fever.
M. H. Peterson, Chicago, Status of Socialized Medicine.

The annual dinner will be held Friday at 7:30 p.m. Dr. Fishbein will give the address on "The Medical Hucksters."

NEW YORK

Postgraduate Lecture—The Medical Society of the State of New York in cooperation with the New York State Department of Health has arranged a Postgraduate lecture for the Seneca County Medical Society at the Armitage Tea Room, Seneca Falls, May 27 at 2:30 p.m. Dr. Paul C. Clark, Syracuse, will speak on "Recent Advances in Therapeutics."

Emergency Service in Erie County.—Erie County has established a round the clock emergency medical service whereby an inquirer is given the telephone numbers of several physicians available at that particular hour when he cannot locate his own physician. In the first nineteen days of operation ninety-nine calls were handled, of which eighty-seven were classed as emergencies.

Establish Toxicology Division.—The University of Buffalo School of Medicine has established a toxicology division which will be supported jointly by the university and the County of Erie. The unit will work closely with city and county authorities, with hospitals and with industry in the determination of poisons. Director of the toxicology division is Dr. Niels C. Klendshoj, associate in pathology, working under Dr. Kornel Terplan, head of the department of pathology. Mr. Milton Feldstein, who had experience in this field at Bellevue Hospital, New York, and in the Army Sanitary Corps, was brought here to assist in this work. The Buffalo General and Meyer Memorial hospitals already have working arrangements with the laboratory, and efforts are under way to enlist the cooperation of other hospitals.

New York City

Dedicate Hospital Wing.—Dedication ceremonies were held for the $1,000,000 McNally Pavilion, a new wing of St. Clare's Hospital, April 18, making capacity of the hospital four hundred and forty-three beds. The wing is a memorial to Mr. and Mrs. Michael J. McNally and Miss Marguerite E. McNally, parents and sister of State Supreme Court Justice James B. McNally.

Dr. Woolley Receives Award.—The first research award of the American Pharmaceutical Manufacturers Association, which met in Havana, Cuba, April 12-17, was presented to Dilworth W. Woolley, Ph. D., aged 33, a blind associate member of the Rockefeller Institute. By his study of the antimetabolite of pellagra he has contributed to public health in those Latin American countries where pellagra has long been prevalent.

Annual Jones Lecture.—Sir Reginald Watson-Jones, British orthopedic surgeon, will deliver the eighteenth annual Sir Robert Jones Lecture at 8:30 p.m. Monday, May 24, at the Hospital for Joint Diseases on "Death and Growth of Bone." The lecture is part of a three-day Alumni Conference of the hospital, which will be held from May 24-26. Sir Reginald is the director of orthopedic and accident service of the London Hospital, London, as well as chief civilian consultant in orthopedic surgery to the Royal Air Force. The Jones lectures were established in 1930 in honor of the man who many consider the father of modern orthopedics. Sir Robert died in 1933.

Dr. Rousselot Appointed Clinical Professor. —Dr. Louis M. Rousselot, associate in surgery at Columbia University College of Physicians and Surgeons, has been appointed professor of clinical surgery at New York University College of Medicine and director of surgery at St. Vincent's Hospital. Dr. Rousselot will devote his full time as director of surgery at St. Vincent's Hospital, beginning August 1. Dr. Rousselot received his medical degree from Columbia University College of Physicians and Surgeons in 1927. He has been affiliated with Babies' Hospital since 1934, has been assistant attending surgeon at Presbyterian Hospital since 1930 and chief of the surgical clinic at Vanderbilt Clinic from 1939 to 1948.

Project to Study Job Ailments. — The Columbia University School of Public Health and Goodwill Industries of New York, Inc., have initiated research to help crippled persons by an accurate scientific analysis of their disability and the jobs they can do. The program will be set up at the "fatigue laboratory" in the workshop of Goodwill Industries. Columbia University will furnish physicians and nurses to conduct the program and will use it as a graduate training center. Dr. Leonard J. Goldwater, professor of industrial hygiene and director of instruction and research, said that all Columbia students in industrial medicine and the majority of the third year medical students in the College of Physicians and Surgeons will be assigned to Goodwill for instruction. The program was made possible by a gift of $25,000 from the Milbank Memorial Fund.

OREGON

State Health Council.—The Council of the Oregon State Medical Society at its meeting April 3 voted to sponsor an Oregon State Health Council and directed the Committee on Public Health, with Dr. Leslie S. Kent, Eugene, chairman, to make plans for its organization. Over a year ago the council issued a recommendation that all component societies assume the leadership in establishing countywide health councils. The Committee on Public Health will also assume responsibility for stimulating and assisting county council development. The Multnomah County Medical Society has sponsored a health council for nearly two years, and one is being organized in Malheur County, also under leadership of the county medical society.

PENNSYLVANIA

Fifty Year Practioners.—The first councilor district of the Medical Society of the State of Pennsylvania and the Woman's Auxiliary held a testimonial dinner May 19 to honor twenty-three physicians who have been in practice for fifty years. They are Oscar E. Boericke, Robert Boyer, Harry K. Carey, Frank A. Craig, George S. Crampton, John M. Cruice, Damaso deRivas, Harry M. Eberhard, Wilfred B. Fetterman, Charles R. Haig, Eugene T. Hinson, Henry C. F. Kellner, Richard W. Larer, Morris V. Leof, Catharine MacFarlane, Albert C. Menger, Charles F. Mitchel, George E. Pfahler, Herbert J. Smith, Stephen E. Tracy, George W. Truitt, Milton N. White and Nathaniel S. Yawger. Dr. Elmer Hess, Erie, president of the state medical society, made the presentations. The dinner address was given by Dr. Edward Bortz, Philadelphia, President of the American Medical Association, on "Mechanism and Humanism in Medicine."

Philadelphia

Cancer Hospital Dedicates Building.—The James Harvey Gravell Supervoltage Building, a part of the American Oncologic Hospital, was dedicated recently in Philadelphia. The building was presented to the hospital by Leon R. Cherksey, president of the American Chemical Paint Company, in memory of the late James Harvey Gravell, founder of the company. The reinforced concrete walls average 27 inches in thickness. The x-ray machine, capable of being stepped up to 5,000,000 volts, was presented at the same time by L. D. Cassett, retired Philadelphia businessman, in memory of his mother.

Books for War Devastated Countries.—The Association of Internes and Medical Students at Woman's Medical College of Pennsylvania has inaugurated a project of sending medical books and journals to war-devastated countries. They have sent 2,000 pounds (907 Kg.) to Prague, Czechoslovakia, to be distributed there through the Unitarian Service Committee or the International Students Union, and 2,000 pounds to China through the China Aid Council in New York. Used instruments are also urgently needed, as well as funds for drugs and vitamins. Any journals or used instruments sent to the Association of Internes and Medical Students at Woman's Medical College will be packed and shipped directly by the organization.

GENERAL

Group for the Advancement of Psychiatry.—About a hundred and fifty members of the American Psychiatric Association have organized a group for the advancement of psychiatry, and subcommittees have been appointed. For information write to Dr. Henry Brosin, Secretary, Group for the Advancement of Psychiatry, c/o University of Chicago, Chicago.

New England Health Institute.—The 1948 session of the New England Health Institute is to be held at the University of Massachusetts, Amherst, June 16-18, as a joint session with the Massachusetts Public Health Conference. University rooming and and dining facilities will be available to delegates from official and voluntary health agencies throughout the area.

Congress on Orthopaedic Surgery and Traumatology.—The Fourth Congress of the International Society of Orthopaedic Surgery and Traumatology will be held in Amsterdam, Netherlands, September 13-18. Speakers on the treatment of osteoarthritis of the hip include Padovani, France; Zahradnicek, Czechoslovakia; La Chapelle, Netherlands; Delchef, Belgium; Wiberg, Sweden; Mathieu, France, and Smith-Petersen, United States. Those discussing closed injuries to the spine are Nicoll, Great Britain; Bohler, Austria; Pais, Italy; Inclan, Cuba and San Ricart, Spain. Orthopedic surgeons in Europe at the time of the congress are invited and should notify Dr. J. Delchef, secretary general, Rue Montoyer 34, Bruxelles, Belgique; Dr. J.D. Mulder, secretary of the congress, Vondelstraat 75, Amsterdam, Pays-Bas, and Dr. Henry W. Meyerding, president of the congress, 102-110 Second Avenue, S.W., Rochester, so that hotel reservations may be made.

Special Libraries Association.—Major General Paul R. Hawley, U.S. Army Medical Corps, retired, former director of medical services of the Veterans Administration, will be the chief speaker at a luncheon of librarians in the biologic sciences and hospital and nursing librarians groups of the Special Libraries Association during the thirty-ninth annual convention of the association in Washington, D. C., June 6-12. Col. Joseph H. McNinch, Washington, D. C., director of the Army Medical Library, will be a guest at this meeting. At another joint meeting of the two groups on Thursday, June 10, Dr. Edward H. Cushing, Washington, D. C., will discuss "The Residency Program in Veterans Administration Hospitals."

Nutrition Awards.—At the annual dinner of the American Institute of Nutrition, Atlantic City, N. J., March 16, the following awards were made: 1. The Mead Johnson and Company Award for work on vitamin B complex was presented to Fritz Lipmann, Ph.D., Boston, head of the Biochemical Research Laboratory of Massachusetts General Hospital "for his work on the identification of pantothenic acid as a component of coenzyme A and to the recognition of its biochemical role in enzymatic acetylation and in the biological oxidation of acetic acid." Dr. Lipmann received the Carl Neuberg Medal of the American Society of European Chemists and Pharmacists for this same research contribution. 2. The Borden Award for distinctive research which has emphasized the nutritive significance of the components of milk or of dairy products was presented to Charles A. Cary, Riverdale, Md., chief, Division of Nutrition and Physiology, Bureau of Dairy Industry, U. S. Department of Agriculture, for his "research concerning the influence of diet on the composition of blood and milk constituents; occurrence and losses of carotene in roughage; vitamin A potency of milk and butter and the relation of same to the quality of roughage; unidentified nutrients necessary for normal growth which are found in milk and milk products, and in certain other foods and feeds."

Society for Vascular Surgery.—The Society for Vascular Surgery will hold its second annual meeting June 20 at the Stevens Hotel, Chicago, under the presidency of Dr. Arthur W. Allen, Boston. The program includes:

Arthur W. Allen, Boston, Venous Thrombosis and Pulmonary Embolism.
John Homans, Boston, Venous Thrombosis in the Lower Limbs.
Michael E. DeBakey and E. W. Alton Ochsner, New Orleans, Gangrene as a Complication of Thrombophlebitis.
Claude S. Beck, Cleveland, Revascularization of the Heart.
Geza de Takats, Chicago, Corticoadrenal Factor in Essential Hypertension.
Herman E. Pearse, Rochester, N. Y., Cellulose and Cellophane Products in Vascular Surgery.
Daniel C. Elkin and Frederick W. Cooper Jr., Atlanta, Ga., Radioactive Isotopes in the Investigation of Vascular Disease.
Ross Veal, Washington, D.C., Surgical Treatment of Hyperhidrosis.
Frederick A. Coller, Kenneth N. Campbell, and Robert E. L. Berry, Ann Arbor, Mich. and Bradley M. Harris, Ypsilanti, Mich., Lumbar Sympathectomy in Advanced Arteriosclerosis Obliterans.
Reginald H. Smithwick and George P. Whitelaw, Boston, Effect of Sympathectomy on Heart Rate.
Louis G. Herrmann and Joseph A. Buchman, Cincinnati, Complications from Injuries to Arteries.
Arthur H. Blakemore, New York, Portacaval Anastomosis for Portal Hypertension.
I. Mims Gage, New Orleans, Cardiac Decompensation Secondary to Arteriovenous Fistula.
Norman E. Freeman, San Francisco, A Technic for Division and Suture of the Patent Ductus Arteriosus.
Robert R. Linton, Brookline, Mass., Treatment of Arteriosclerotic Popliteal Aneurysm.

Report of Interim Commission.—At the fifth session of the World Health Organization Interim Commission in Geneva, Switzerland, January 22-February 7, the report on the activities of the commission since its establishment at the International Health Conference in New York in 1946 was approved for submission to the World Health Assembly in Geneva June 24 - July 31. The proposed 1949 budget for the World Health Organization amounts to $6,367,995, of which $1,071,690 is allotted for fellowships, medical literature, teaching equipment and emergency medical supplies. Major recommendations by the commission to the first World Health Assembly and W.H.O. include the following: (1) Continuation of medical cooperation with accredited governmental and nongovernmental agencies. It recommends that the World Health Organization serve in an advisory capacity in the fields of public health and medicine with the International Civil Service Advisory Board, the United Nations Social Commission, the U. N. Scientific Conference for the Conservation and Utilization of Resources, International Labor Organization United Nations Educational, Scientific Cultural Organization. It recommended that aid be continued to the International Children's Emergency Fund in launching an antivenereal campaign among children and woman through mass treatment with penicillin; (2) Continuation of the epidemologic service and revision of existing sanitary conventions; (3) continuation of the work of biologic standardization and unification of pharmacopeias, (4) creation of an international influenza center, which is now well under way; (5) revision of the international lists of diseases and causes of death; (6) appointment of a designated representative of countries not having a scientific attaché in the United States for distribution of radioactive isotopes by the United States; (7) promotion of health protection for children; (8) programs of malaria, tuberculosis and venereal disease control, and maternal and child health; (9) continuation of field services and medical mission sent under UNRA to various countries.

Marriages

ALBERT HEWETT COONS, Boston, to Miss Phyllis E. F. Watts of Milton in December 1947.

FORREST CLARENCE ORMAN, Roanoke, Va., to Miss Mary Virginia Leonard of Galax, Dec. 6, 1947.

JOHN E. GOTTSCH, Shenandoah, Iowa to Miss Rachel E. Updegraff of Sigourney in New Orleans, January 31.

CORRECTIONS

Preliminary Program of Scientific Assembly—In THE JOURNAL, May 15, in the program of the Section on Ophthalmology, Wednesday, June 23, the title of the fourth paper, by Theodore H. Ingalls, "Epidemiology of Encephalo-Ophthalmic Dysplasia," was omitted; in the program of the Section on Pediatrics, June 23, the last name among the authors of the fourth paper should be "Herman" not "Herbert" N. Bundesen; in the Section on Pathology and Physiology, Friday, June 25, the authors of next to the last paper should have read: "Lester M. Morrison, Lillian M. Hall, Albert L. Chaney and William Gonzales."; in the Section on Gastro-Enterology and Proctology, June 23, the name of one of the authors of the last paper should have been "D. F. Richfield" instead of "Richkield;" in the Section on Miscellaneous Topics, Session on Physical Medicine, the third paper to be presented in the Panel Discussion on "Physical Treatment of Poliomyelitis" by Robert L. Bennett, Warm Springs, Ga., was omitted.

Deaths

Hill Hastings ⊕ Los Angeles; born in Elizabethtown, Ky., Jan. 9, 1874; University of Virginia Department of Medicine, Charlottesville, 1895; an Affiliate Fellow and in 1915-1916 chairman, Section on Laryngology, Otology and Rhinology of the American Medical Association; emeritus professor of surgery (otology, rhinology and laryngology), University of Southern California School of Medicine; member and formerly vice president of the American Laryngological Association; member and past president of the Los Angeles Society of Oto-Laryngology and the American Laryngological, Rhinological and Otological Society; member of the Pacific Coast Oto-Ophthalmological Society; assistant surgeon, U.S. Public Health Service, from 1897 to 1902; captain in the medical corps of the U.S. Army during World War I; affiliated with Los Angeles County General Hospital, Children's Hospital and the Good Samaritan Hospital, where he died February 14, aged 74, of bronchopneumonia.

William Lowndes Peple ⊕ Richmond, Va.; born in Manchester, Va., Dec. 5, 1875; University College of Medicine, Richmond, 1897; emeritus professor of clinical surgery at the Medical College of Virginia; member of the founders' group of the American Board of Surgery; member and formerly vice president of the Southern Surgical Association and of the Medical Society of Virginia; fellow of the American College of Surgeons; past president of the Richmond Academy of Medicine and the Tri-State Medical Association; served in France during World War I; for many years associated with St. Luke's Hospital; died February 7, aged 73, of cerebral hemorrhage.

Fred Franklin Attix ⊕ Lewistown, Mont.; born in Detroit Lake, Minn., Aug. 8, 1878; University of Pennsylvania Department of Medicine, Philadelphia, 1900; past president of the Montana State Medical Association; member and formerly vice president of Western Surgical Association; member of the American Association for the Surgery of Trauma and the Radiological Society of North America, Inc.; member of the founders' group of the American Board of Surgery; president of staff, St. Joseph's Hospital; founder and president, Attix Private Clinic Hospital; district surgeon, Chicago, Milwaukee, St. Paul and Pacific Railroads; died February 9, aged 69;

Harry Kraylor Born ⊕ Los Angeles; born in Indianapolis, Aug. 9, 1886; Indiana University School of Medicine, Indianapolis, 1908; associate clinical professor of surgery at the College of Medical Evangelists; member of the founders' group of the American Board of Surgery; member of the Western Surgical Association; fellow of the American College of Surgeons; affiliated with Presbyterian Hospital-Olmsted Memorial; attending surgeon, Los Angeles County Hospital and member of the senior staff of the California Hospital; died in the Methodist Hospital February 8, aged 61, of cerebral hemorrhage and essential hypertension.

Louis Abraham Feldman ⊕ Brooklyn; born in Brooklyn in 1890; University and Bellevue Hospital Medical College, New York, 1914; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; formerly affiliated with the Indian Service in White Earth, Minn.; fellow of the American College of Surgeons; affiliated with the Brooklyn Hebrew Home and Hospital for Aged and the Jewish Hospital; attending ophthalmologist to Sea View Hospital, Staten Island; died in Palm Beach, Fla., February 2, aged 57, of cerebral hemorrhage.

Alfred Franklin Hocker ⊕ New York; born in Audubon, Iowa, April 29, 1902; University of Louisville (Ky.) School of Medicine, 1926; assistant professor of radiology at the Cornell University Medical College; specialist certified by the American Board of Radiology, Inc.; member of the American College of Radiology and the American Radium Society; director of the tumor clinic at the Cornwall (N.Y.) Hospital; on the staffs of the Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York Hospital and the White Plains (N.Y.) Hospital; died February 12, aged 45, of coronary thrombosis.

Isaac Spencer Finney Dodd ⊕ Pittsfield, Mass.; born in Hangchow, China, Feb. 28, 1868; University of the City of New York Medical Department, New York, 1890; member of the founders' group of the American Board of Surgery; fellow of the American College of Surgeons; past president of the Berkshire District Medical Society; served during World War I; on the staff of the Fairview Hospital in Great Barrington, House of Mercy and St. Luke's Hospital; died in the Palmer Memorial Hospital, Boston, January 30, aged 79, of carcinoma of the colon.

John Wilson Poucher, Poughkeepsie, N.Y.; born in Claverack, N.Y., July 24, 1859; Albany (N.Y.) Medical College, 1883; instrumental in the organization of the Dutchess-Putnam Medical Society, which he served as president; fellow of the American College of Surgeons; veteran of the Spanish-American War; for many years affiliated with the Vassar and St. Francis hospitals; served as manager and president of the board of the Hudson River State Hospital; for many years secretary of the Dutchess County Historical Society; died February 16, aged 88, of arteriosclerosis.

Frank E. Andrews, Norfolk, Va.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1904; found dead February 18, aged 80.

Francis Richard Anthony, Maryville, Mo.; Missouri Medical College, St. Louis, 1898; member of the American Medical Association and in 1907 member of its House of Delegates; past president of the Nodaway County Medical Society; died in St. Francis Hospital February 16, aged 75, of a hip fracture received in a fall.

Glenn Wyatt Arthurs, Niagara Falls, N.Y.; University of Buffalo School of Medicine, 1918; member of the American Medical Association; served during World War I; on the staffs of the Memorial and Mount St. Mary's hospitals; died February 10, aged 52, of coronary thrombosis.

Lewis Harlan Athon, Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; member of the American Medical Association; on the staff of the Methodist Hospital; died February 26, aged 60, of carcinoma.

Harold Woods Baker, Orford, N.H.; Harvard Medical School, Boston, 1906; fellow of the American College of Surgeons; at one time an assistant at the Mayo Clinic in Rochester, Minn.; served on the faculty of his alma mater and on the staffs of the Charlesgate Hospital in Cambridge, Mass., and the Free Hospital for Women in Brookline, Mass.; died February 14, aged 66, of hypertension and cerebral thrombosis.

Irving Sydnor Barksdale, Greenville, S.C.; Yale University School of Medicine, New Haven, 1923; member of the American Medical Association; at one time on the faculty of the Medical College of the State of South Carolina in Charleston; for many years city health officer; died in St. Francis Hospital February 10, aged 50, of cerebral hemorrhage.

Julius Peter Karp, Hartford, Conn.; Maryland Medical College, Baltimore, 1913; Kansas City College of Medicine and Surgery, 1917; died in the Hartford Hospital February 14, aged 69, of coronary disease.

Felix Max Katar, Philadelphia; Maryland Medical College, Baltimore, 1910; member of the American Medical Association; died Dec. 7, 1947, aged 77, of coronary sclerosis.

Joseph Adelbert Keithley, Palmyra, Wis.; Illinois Medical College, Chicago, 1902; past president of the Jefferson County Medical Society; served during World War I; died in Lakeland, Fla., January 15, aged 73, of coronary thrombosis.

Arthur Edward Lamley ⊕ Blissfield, Mich.; Medico-Chirurgical College of Philadelphia, 1909; served as health officer and county coroner; died in Bixby Hospital, Adrian, February 10, aged 62, of primary atypical pneumonia.

Erwin Last ⊕ New York; Universität Bern Medizinische Fakultät, Switzerland, 1919; member of the New York Post Graduate Hospital; died February 12, aged 52, of coronary thrombosis.

Eugene Joseph Leopold ⊕ Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1905; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; on the staffs of the Johns Hopkins and Sinai hospitals; died January 14, aged 68.

Emry Franklin Lewis, Ada, Okla. (licensed in Oklahoma under the Act of 1908); died January 13, aged 82.

Philip A. Ley, Donora, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1904; also a graduate in pharmacy; member of the American Medical Association; served as school director, member of the board of health and medical examiner for the public schools; died February 5, aged 68, of carcinoma of the liver.

Walter Mathews Lott ⊕ Nashville, Tenn.; Emory University School of Medicine, Atlanta, 1918; served during World War I; died February 15, aged 53, of carcinoma of the stomach.

William Barker McCreery ⊕ Tacoma, Wash.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1902; fellow of the American College of Surgeons; on the staffs of the Tacoma General and St. Joseph's hospitals; died Dec. 28, 1947, aged 73, of coronary disease.

Wilbur Washington Mackenzie, Los Angeles; College of Physicians and Surgeons, Chicago, 1896; fellow of the American College of Surgeons; died recently, aged 78.

John M. Meadows, Vidalia, Ga.; University of Georgia Medical Department, Augusta, 1888; member of the American Medical Association; died January 22, aged 86.

Walter McDonald Merritt, Boyle, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1906; member of the American Medical Association; served during World War I; formerly assistant superintendent of the State Insane Hospital, Asylum; died in Baptist Hospital, Memphis, Tenn., February 1, aged 65, of heart disease.

Joseph Bennedick Metzger, Toledo, Ohio; Ohio State University College of Medicine, Columbus, 1915; member of the staff of St. Vincent's Hospital; died January 24, aged 64.

David G. Miller, Doraville, Ga.; University of Georgia Medical Department, Augusta, 1887; died January 20, aged 84.

F. A. Minnis, Phoenix, Ariz.; Tennessee Medical College, Knoxville, 1907; died in the Good Samaritan Hospital February 7, aged 74.

Robert Sterling Montgomery ⊕ South Hill, Va.; Medical College of Virginia, Richmond, 1934; physician to the Selective Service Board during World War II; died February 9, aged 37, of amyotrophic lateral sclerosis

Julia Morgan, Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1920; diplomate of the National Board of Medical Examiners; associate in medicine at her alma mater formerly a medical missionary in China, where she was on the faculty of the Cheeloo University School of Medicine, Tsinan, Shantung; received the honorary degree of doctor of science from Dickinson College, Carlisle, Pa.; died in the University of Pennsylvania Hospital January 26, aged 56, of coronary sclerosis.

Thomas Morgan, Alton, Ill.; Baltimore Medical College, 1895; died in St. Joseph's Hospital February 1, aged 76, of injuries received when struck by an automobile while he was crossing the street.

Ernest Mosby, Waynesboro, Va.; Medical College of Virginia, Richmond, 1899; died February 5, aged 71.

William Archibald Murray, Scranton, Pa.; Jefferson Medical College of Philadelphia, 1929; member of the American Medical Association; affiliated with Mercy Hospital, where he died February 14, aged 53, of heart disease.

Sverre Oftedal ⊕ Glendale, Calif.; Rush Medical College, Chicago, 1911; fellow of the American College of Surgeons; on the staff of the Physicians and Surgeons Hospital; died February 4, aged 64.

Francis Michael Pare, Worcester, Mass.; Georgetown University School of Medicine, Washington, D.C., 1931; member of the New England Obstetrical and Gynecological Society and the American Medical Association; affiliated with St. Vincent's Hospital, where he died January 28, aged 45, of lymphoblastoma.

Ralph Wait Parsons, Seattle; College of Physicians and Surgeons, medical department of Columbia College, New York, 1890; at one time physician in charge of the Greenmont-on-the-Hudson in Ossining, N.Y., where he practiced medicine and was a member of the library board; died January 29, aged 80, of carcinoma of the prostate.

Judson Philbrook Pendleton ⊕ Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1898; fellow of the American College of Physicians; past president of the Brooklyn Pediatric Society; affiliated with the Coney Island, Kingston Avenue, Cumberland Street and Methodist hospitals; died January 21, aged 74.

Anthony Salvatore Pendola, Holyoke Mass.; Middlesex College of Medicine and Surgery, Cambridge, 1920; member of the American Medical Association; served during World War I; formerly assistant physician affiliated with the Providence and Holyoke hospitals; died January 10, aged 57, of carcinoma.

Clarence George Perry, St. Paul; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; member of the American Medical Association; served during World War I; died in Pharr, Texas, January 6, aged 62, of coronary occlusion.

Thomas Adolphus Peterson ⊕ Wynne, Ark.; University of Tennessee College of Medicine, Memphis, 1932; died February 3, aged 40.

Harold Ashton Pingree, Portland, Maine; Medical School of Maine, Portland, 1901; member of the American Medical Association; formerly on the faculty of his alma mater; fellow of the American College of Surgeons; served with the U. S. Public Health Service; affiliated with the Maine General and Children's hospitals; died January 7, aged 70, of heart disease.

Eva Prescott, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; died February 3, aged 71.

Arthur Augustus Rankin, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; died in the Fairview Hospital January 4, aged 75, of a rupture of the left cardiac ventricle.

Maten Floyd Rathbun, Hanover, Ill.; Chicago Medical School, 1921; served during World War I; died January 25, aged 53.

Frederick Bangs Rawlings ⊕ Sandersville, Ga., University of Pennsylvania School of Medicine, Philadelphia, 1915; member of the Southeastern Surgical Congress and the Southern Medical Association; past president of the Washington County Medical Society; fellow of the American College of Surgeons; served overseas with the Emory Unit during World War I; senior surgeon of Rawlings Sanitarium; died in the Emory University Hospital, Atlanta, January 16, aged 58, of carcinoma of the pancreas.

Claude Everett Richmond ⊕ Colorado Springs, Colo.; Barnes Medical College, St. Louis, 1909; past president of the El Paso County Medical Society; specialist certified by the American Board of Anesthesiology, Inc.; member of the American Society of Anesthesiology; affiliated with the Glockner-Penrose Hospital, Memorial Hospital and the St. Francis Hospital and Sanatorium; died February 4, aged 60, of coronary thrombosis.

Ralph Weller Rucker, Bartlesville, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1936; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; past president of the Washington-Nowata Counties Medical Society; served during World War II; died in Norman January 27, aged 37, of injury received in a fall.

Emil Albin Rundquist ⊕ New York; Columbia University College of Physicians and Surgeons, New York, 1898; fellow of the American College of Surgeons; formerly on the faculty of the New York Post-Graduate Medical School and Hospital, Columbia University; died in January, aged 72.

Charles Morehead Smith, Dixon, Ky.; Missouri Medical College, St. Louis, 1885; member of the American Medical Association; secretary of the Webster County Medical Society; for many years health officer of Webster County; died in the Vanderbilt Hospital, Nashville, Tenn., January 28, aged 84, following an operation for cholelithiasis.

Herbert Lee Sproul, Waverly, N.Y.; Long Island College Hospital, Brooklyn, 1895; died January 25, aged 78, of arteriosclerotic heart disease.

Fred Wilson Standefer ⊕ Lubbock, Texas; University of Texas School of Medicine, Galveston, 1917; served overseas during World War I; associated with the West Texas Hospital and Clinic; died January 22, aged 54, of heart disease.

Gordon Livingston Todd, Princeton, W. Va.; University of Virginia Department of Medicine, Charlottesville, 1910; member of the American Medical Association; fellow of the American College of Surgeons; owner and medical director of the Mercer Memorial Hospital; died February 3, aged 63, of heart disease.

Thomas Tilghman Tolson, Longstreet, La.; Chicago College of Medicine and Surgery;. 1914; died at the Tri-State Hospital in Shreveport January 22, aged 57.

William Porter Verity, Two Buttes, Colo.; Rush Medical College, Chicago, 1879; member of the American Medical Association; for many years county coroner; died in the Sacred Heart Hospital, Lamar, January 13, aged 94.

Paul Henry von Zierolshofen ⊕ Croghan, N. Y.; University of the City of New York Medical Department, New York, 1887; served during World War I; for many years fire chief; affiliated with the Lewis County Hospital in Lowville and St. Lawrence State Hospital in Ogdensburg; vice president of the Croghan National Bank; died January 20, aged 84, of coronary occlusion.

John A. Waggener, Humboldt, Neb.; Louisville (Ky.) Medical College, 1876; member of the American Medical Association; past president of the Richardson County Medical Society; served as county coroner; died January 23, aged 95.

John Edward Walton ⊕ Alton, Ill.; Marion-Sims College of Medicine, St. Louis, 1897; past president of the Madison County Medical Society; member and formerly chief of staff, Alton Memorial Hospital; served during World War I; died January 25, aged 80, of coronary occlusion.

Philip Carter Washburn, Morris Plains, N. J.; Columbia University College of Physicians and Surgeons, New York, 1900; an officer during World War I; for many years on the staff of the New Jersey State Hospital at Greystone Park; formerly on the staffs of the Manhattan and Kings Park State hospitals in New York; died January 10, aged 72, of coronary thrombosis.

John Cowden Welch, Bellevue, Pa.; Medico-Chirurgical College of Philadelphia, 1893; district registrar of vital statistics; founder and original staff member of St. John's General Hospital in Pittsburgh; affiliated with the Suburban General Hospital, where he died February 3, aged 80, of cerebral thrombosis and diabetes mellitus.

Benjamin Franklin Williams, Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1910; died January 8, aged 64.

Millard Lewis Wilson, Falls City, Neb.; Lincoln Medical College of Cotner University, 1896; member of the American Medical Association; served as mayor of Humboldt, as coroner and health officer of Richardson County; affiliated with Our Lady of Perpetual Help Hospital, where he died January 28, aged 80, of acute gangrenous appendicitis.

Charles F. Wixom, North Cohocton, N. Y.; University of Buffalo School of Medicine, 1892; died in the Wayland (N.Y.) Hospital January 20, aged 88, of arteriosclerosis.

John George Wurtz ⊕ Philadelphia; Hahnemann Medical College and Hospital, Philadelphia, 1907, and Jefferson Medical College of Philadelphia, 1908; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; affiliated with the Women's Homeopathic Hospital, where he died January 15, aged 62, of cerebral hemorrhage.

Blood Transfusion Service for London Hospitals

During and since the war blood transfusion has greatly developed and services have been organized all over the country. The Greater London Blood Transfusion Service, which covers London and five adjoining counties, serves fifty hospitals. The service is responsible for the supply of donors in cases in which freshly drawn blood is essential. Every call is for a definite patient (there is no blood bank), and therefore the urgency of the demand is brought home to the donor. As the service has become known, the number of calls has increased. There were 1,095 requests in 1945, 1,863 in 1946 and 2,436 in 1947. In January 1948 the number was 273. The most received in any one day was 27.

On enrollment, donors undergo medical examination, their blood is tested and grouped by the medical officer of the service, Dr. H. F. Brewer, at the pathologic department, St. Bartholomew's Hospital. The service can supply not only Rh-negative and Rh-positive donors of the A, B, AB and O groups but also donors of the rare Rh subgroups for both transfusion and research purposes. No maximum is fixed for any one donor. More than half have given blood over ten times, and more than a fourth over twenty times. One donor has served more than one hundred times, and the seventieth birthday of another was celebrated by the seventieth transfusion, though 65 is the usual age limit. The minimum period between donations is three months for men and four months for women. In only 2 of 60,000 cases has the service learned that the donor's health has suffered temporarily from the donation. But all donors are insured against ill effects and are examined after the completion of each ten transfusions. The donors are not paid for their services but are reimbursed for their expenses.

Cardiac Catheterization

At a joint meeting of the Manchester Medical and Pathological Societies Professor J. McMichael lectured on cardiac catheterization, which was introduced by Forssman in 1929. Subsequently it was used extensively in Portugal, France and Latin America to inject radiopaque substances so as to define vessels at the root of the lung. In 1941 Cournand described its use for measuring pressure in the chambers of the heart and for measuring the cardiac output by the Fick principle. Use of the method in the London Postgraduate School has been without untoward incident in 800 cases and is now spreading widely. Blood never clots on the surface of the catheter, but small pinhead thrombi occasionally form on the tip, and some may escape into the lungs, where there is good reason to believe that they are harmless. In the right ventricle the tip may excite extrasystoles, which may be harmful to patients whose cardiac condition is precarious. One death has been reported in the Netherlands in a case of gross coronary disease.

In congenital heart disease the simpler defects may often be diagnosed by cardiac catheterization. A defect of the interauricalar septum is recognized by the admixture in the right auricle of arterial and venous blood. But the selection of cases for Blalock's operation is usually made on clinical grounds. Bing's recent success in sampling blood from the coronary sinus has opened possibilities. Cardiac catheterization has come to stay.

Precautions Against Harmful Results of Atomic Research

An establishment for research on atomic energy has been installed at Harwell, on the Thames, by the government. Precautions have been taken, on the advice of the Medical Research Council's research committee on the medical and biologic application of nuclear physics, to insure that the water used is returned to the Thames free from the risk of harmful radioactivity. A certain amount of radioactivity in drinking water can be tolerated by human beings, and the Medical Research Council has laid down a tolerance for Thames water such that the effects of consumption will be negligible. About a million gallons of water will be used daily at the research station. Most of it will be for cooling plant and domestic needs. The rest will be for research purposes, some of them radioactive. A carefully controlled water system will be installed. The most highly active portion of the water will be segregated and withheld from the river. The remainder will be passed to storage tanks, where it will be (1) tested by medical officers for compliance with the agreed tolerances, (2) treated for chemical impurities, and then (3) mixed with the domestic water before being discharged into the Thames.

The system of treatment and examination has been so devised that several operations have to be carried out before the water is discharged. A new weir is being constructed at the point of discharge so that the water will be turbulently mixed with much greater quantities of river water before it joins the main stream. These safeguards have received the approval of the Ministry of Health.

Orthopedic Surgery in Rheumatiod Arthritis

At the Section of Physical Medicine of the Royal Society of Medicine Mr. A. W. Law opened a discussion on orthopedic surgery in rheumatoid arthritis and ankylosing spondylitis. He had lately spent some months at the Massachusetts General Hospital studying the methods of Bauer and Smith Petersen. He said that the orthopedic surgeon is taking a greater share in overcoming the deformities of these diseases. The team work of a physician, an expert in physical medicine and an orthopedic surgeon is necessary, and in certain cases high voltage roentgen therapy may also be required. The principle of rest is still the basis of the so-called conservative treatment of rheumatoid arthritis, but it may be harmful from the point of view of restoration of function. A careful balance must be preserved between rest and active exercise, pain being controlled if necessary by drugs. In many rheumatoid cases multiple deformities necessitate a long program of reconstructive or functional treatment. One or more revision operations may be necessary for a satisfactory end result.

Taking first the upper limb, a painful shoulder joint with deformity of adduction and internal rotation is frequent. Excision of the acromion process, with removal of subacromial bursas, eliminates the source of pain and allows free movement. Relief of pain helps to remove muscular spasm. In rheumatoid arthritis of the elbow spasm of the biceps is prominent. *Smith Petersen* has shown that the radial head may be drawn upward so as to impinge on the capitellum. Excision of the radial head overcomes such faulty joint mechanics, pain is relieved and a considerable improvement in range is obtained. When there is gross destruction or complete ankylosis excision of the lower end of the humerus and upper ends of the radius and ulna is indicated. The hip and knee joints frequently require surgical treatment on account of pain and deformity with a variable degree of ankylosis. When the patient's morale is low and the muscles wasted and fibrotic a stabilizing process such as athrodesis may be useful. The problem of bilateral stiff hips and knees may have to be faced. A reconstructive operation before fibrosis of muscles and joints has progressed too far should be performed. The technic of Smith Petersen's arthroplasty of the hip, to create all the elements of the joint, has been greatly improved by the use of the " vitallium " mold, which becomes a barrier to recurring ankylosis. Any reconstruction of the hip joint must produce a joint which is painless, stable and capable of bearing weight.

Eire Doctors Reject a State Medical Service

Evidently as a result of the British proposal, the question of a state medical service has been raised in Irish politics. A special meeting of the Medical Association of Eire has been held to discuss the White Paper on the Eire Health Act of 1947. The meeting unanimously passed the following resolutions: (1) that many of the provisions of the health act of 1947, as outlined in the White Paper, are unworkable, and (2) that the central council of the Medical Association of Eire is opposed to the taking over or direction by the state of all medical services and to the degree of state control and direction that is visualized.

Experimental Psychology: A New Journal

Increasing interest in experimental pathology has led the Experimental Psychology Group to found a new journal, the *Quarterly Journal of Experimental Psychology*. Editorial inquiries should be addressed to Mr. R. C. Oldfield, M.A., Institute of Experimental Psychology, 34 Banbury Road, Oxford, England. The Journal may be ordered, 7½ s. annually or 2 s. per issue, from W. Heffer & Sons, Ltd., 3-4 Petty Cury, Cambridge, England.

Dentists Reject National Health Service

The British Dental Association announces that the decision of the representative board to recommend members not to enter the National Health Service has been followed by meetings of nine branches at which 1,080 votes were cast against any participation in the service and only 33 in favor of entering it.

ANKARA

(From Our Regular Correspondent)

March 12, 1948

Folic Acid Therapy

A sample of folic acid came to Turkey late in 1946, and Professors Tevfik Saglam and E. Frank, of Istanbul University Hospital, were the first to apply it with excellent results in cases of pernicious anemia.

A patient was given a daily dose of four tablets of folic acid but no liver extract. Reticulocytes, which before treatment had been subnormal, increased to 18 within a week; red blood cells and hemoglobin began to increase accordingly, and the whole blood picture gradually changed. Within eighteen days the red blood cell count rose to 3,850,000, with hemoglobin 68 per cent. After that the patient was given iron and ascorbic acid. A week later the red blood cell count rose to 4,000,000, the hemoglobin level to 72 per cent. The second sternal puncture revealed a decrease of megaloblasts from 30 to 4.5. In the third myelogram on the twenty-ninth day of treatment, megaloblasts had completely disappeared. The number of white blood cells, which before treatment amounted to only 3,000, gradually increased to 7,000 with a resultant great improvement in the patient's health and disappearance of the pains. This had been attained with 500 mg. of folic acid.

Half Century of Children's Hospital

As a memorial to his beloved daughter, the Sultana Haditche, who died of diphtheria at 10 years of age, Sultan Abdul Hamid II established the Istanbul Children's Hospital, which was opened in 1898. It had six pavilions with steam heat, one hundred beds, and was erected at the cost of 40,000 pounds Turkish in gold. Ibrahim pasha, who had been in attendance when the sultana died, was appointed physician in chief. This, the only children's hospital in Istanbul, has during the republic (since 1923) been remodeled. Today it has three hundred beds and departments for every speciality. More than 100,000 persons a year come to the outpatient department. In 1933 Istanbul University was reorganized and the children's hospital became part of it, the department of pediatrics, orthopedics and urology serving as a teaching center for medical students. At present only the department of pediatrics, which is under the direction of Professor Ihsan Hilmi Alantar, serves that purpose. As soon as the children's hospital of the university is finished, it will cease to be a teaching hospital. Two years ago the Ministry of Health added a new building, a nurses' home and a training school for hospital and public health nurses. There are at present one hundred students. The course lasts three years. Under the ten year National Health Plan seven three hundred bed children's hospitals are to be erected in the principal cities and towns.

Infantile Kala-Azar

At the monthly meeting of the Istanbul Medical Society Dr. N. M. Fakacelli of the Austrian Saint George Hospital, Istanbul, reported a case of kala-azar in an infant 13 months of age. According to the mother, who lived in Istanbul on the Bosporus, the onset of fever, lack of appetite, increasing weakness and swelling of the abdomen began four months prior to the child's admission at the hospital in September 1947. Because of the mother's illness, breast feeding had been discontinued after seven months, and the child was fed cow's milk. Plasmodia were not present in the blood smear; coagulation of the blood was normal. Sternal puncture was made the next day, and leishmania were found in splenogram and myelogram. Because the child was in a critical condition and ethylstibamine ("neostibosan") was not available, antimony and potassium tartrate had to be resorted to. A blood transfusion of 30 cc. was given by the father; iron and vitamin preparations were administered. The child died of pneumonia on the seventeenth hospital day.

Dr. Fakecelli discussed the 39 cases of kala-azar which had come to his clinic in the last nine years He said that the formolgel test, Gate and Papacostas tests are a great help in arriving at the diagnosis, but they should not be relied on solely. The tests had been positive in 34 of 39 cases; and undecided in 5. The most reliable method to arrive at a true diagnosis was to search for and locate the parasites in the spleen and bone marrow. In 2 of 18 cases in which parasites had not been found either in the myelogram or the splenogram, an abundance of leishmania had been found in the spleen. Though in the myelogram of 16 patients there had been only a few Leishmania, there were an abundance in the spleen, indicating that the safest method is the splenic puncture. Of 34 patients who every other day received an intravenous injection of "neostibosan," 31 patients recovered. Because "neostibosan" was not available antimony and potassium tartrate had to be resorted to for 6 patients, of whom 3 recovered and 3 died. All 39 patients had come from the Golden Horn and the Bosporus, indicating that in these regions kala-azar is endemic and requires precautionary measures.

Blood Transfusion Centers

A new order of the Ministry for Public Health and Population pertains to blood transfusion centers. Regional centers are under the management of a director assisted by a committee consisting of nine members: (1) a specialist in blood transfusion; (2) a hematologist; (3) a dermatologist; (4) an obstetrician; (5) a surgeon; (6) a representative of blood donors; (7) a representative of the Regional Social Security Fund; (8) a representative of public or private collectives, and (9) a representative of the Syndicate of Doctors. Centers have to insure a supply of preserved blood, fluid or dry plasma, and convalescent serum to medical establishments and district transfusion centers. Regional centers will also take part in scientific research and in the education of the medical corps with regard to blood transfusion; they will cooperate with the National Institute for Hygiene. District centers under the management of public or private collectives will have a consultative committee of six members, and they will assume the recruiting of blood donors and the institution of emergency blood transfusion services.

The national center for blood transfusion is the oldest in the world, having been created in 1923 by Professor A. Tzank, the present director, and by Professors Levy-Sclal and Gosset. Located in an annex of the St. Antoine Hospital, its activities embrace arm to arm transfusions, the preparation of plasma and preserved blood, the control of reactions to transfusions, the registration of future donors and the participation in the organization of regional and departmental centers. To those actitivities add also collaboration with the Percy Hospital Army Transfusion Center. Its official paper is the monthly *Revue d' hematologie.*

Research at the National Center.—Research is progressing in various directions in the Laboratory of the National Center. Caroli and Bessis' research on hereditary erythroblastosis opens a large field of experimentation in human serology and has great scientific and practical value. Bessis and Bernard, who use the exchange transfusion in the treatment of acute leukemia, in collaboration with Buhot have perfected the technic using Diamond's catheter. After exposing a vein at the elbow, the catheter is introduced up to the venous confluent at the base of the neck. Then the blood exchange is performed by means of the two-way syringe (Tzank's type). They believe this method may be applied also in the treatment of intoxications when the poison is still in the blood and the anatomic lesions are not irreversible. Research is in progress to ascertain whether the effective substances in normal blood are carried by the corpuscles, or, if by the plasma, by what fraction of the plasma. The experiments of these and other workers show that in acute leukemia exchange transfusion only produces recovery exceptionally but in all cases prolongs the patient's life. Tzank and Andre have studied post-transfusion reactions in a series of 6,000 transfusions. They conclude that a previous injection of morphine diminishes the frequency of such reactions and that transfusions without anesthesia are practically never followed by accidents. Post-transfusion reactions occur in 15 per cent of cases. While these reactions have no relation to the rapidity of the injection, Tzank and Andre recommend that the first 30 to 40 cc. of blood be injected slowly.

New Pathogenic Concept of American Trypanosomiasis

Drs. Julio Muniz and A. Penna de Azevedo, of the Oswaldo Cruz Institute, Rio de Janeiro, published a paper describing their investigation of the action of Tripanosoma cruzi, causative agent of the American trypanosomiasis, on man. Their main objective was to ascertain the possibility of causing an allergic condition by the inoculation of lysates and suspensions of dead cultures of the parasite. The experiments were performed on the rhesus monkey ((Macaca mulatta), since this animal presents, when infected, an immunologic picture similar to that of human patients suffering from trypanosomiasis.

Two monkeys received five preparatory intravenous injections of the antigen at three day intervals. It is important to emphasize the great tolerance of the rhesus monkey for high doses of the antigen. Although the sensitization of the animals was performed by intravenous injections no violent reactions occurred. Twelve days after the last preparatory injection the animals received the shock injection. One monkey was killed eight days after the shock injection, and the second thirty days after the injection. The second monkey received also three more doses after the shock injection, for a better observation of the evolution of the lesions caused by the shock. The lesions observed were of two different types: in the pleura, hyperergic lesions with inflammatory phenomena and development of granulomas; in the heart muscle, a myocarditis reproducing the exact picture found in human American trypanosomiasis.

To exclude the possibility of a toxic action eventually induced by the antigen, two more monkeys were injected. The first received 5 mg. of a desiccated mass of parasites directly into the heart muscle, and, on the same day, 15 mg. of the same material intravenously. The second rhesus received 312 mg. of humid parasites and 42 mg. of dried parasite mass in five injections given at 5 day intervals. No lesions were found in the pleura or in the heart muscle.

Muniz and Azevedo conclude that the killed parasitic bodies behave in the organism like a heterogenous protein with a high sensitizing power and that the lesions described occur as a consequence of the particular conditions of the sensitization. The heart muscle is more sensitive than all other organs and may be considered as a true "shock organ." The complete similarity of the histopathologic picture presented by the rhesus heart muscle in these experiments and the myocarditis observed in human cases of American trypanosomiasis modify the present concept of the pathogenic role of T. cruzi. The theory of an allergic condition in the pathogenesis of such a myocarditis, as suggested in 1929 by Magarinos Torres, finds here its experimental confirmation.

Correspondence

STATE PLANNING CONFERENCE FOR CHILDREN AND YOUTH

To the Editor:--I recently attended the State Planning Conference for Children and Youth in Washington, D. C. (March 30-April 1, 1948). The conference was called by the National Commission on Children and Youth in order to work out a program of action on the state and community level prior to the White House Conference on Children and Youth for 1950. The conference strongly advised the formation of State Committees for Children and Youth in those states not already having such committees, and that these state committees spearheed the formation of community committees. The theme of the 1950 White House Conference is to be "The Child in His Community." In previous White House conferences, decisions were made on the national level at the time of the conference. It is hoped that a well developed program will be under way in every state and community before the 1950 White House conference convenes.

While there were a number of representatives from state health departments, as far as I have been able to determine from the list of delegates, I was the only official delegate from any state medical society. The conference specifically recommended that each state chairman of the American Academy of Pediatrics be named on the State Committee for Children and Youth. It was recognized that these men would be in a better position to interpret the results of the recent Academy of Pediatrics Study of Child Health Services on a state level. It was also felt that state and county medical societies should be represented on these committees. Interestingly enough, these recommendations came from persons outside the medical profession.

The whole tone of the conference indicated that the layman and members of allied professions were most interested in seeking the leadership and advice of the members of the medical profession. Another healthful sign was the emphasis placed on local planning. While the conference was held under the auspices of the Children's Bureau, the government agencies remained much in the background.

In the months ahead members of the medical profession will be asked to serve on State and Local Committees for Children and Youth. It is an opportunity and a challenge which we cannot afford to overlook.

Carl G. Ashley, M.D., Portland, Ore.

NEUROPSYCHIATRY

To the Editor: The term neuropsychiatry has recently come into vogue, especially among the military. This term is unfortunate, since this word – though listed in Webster – is a bastard and a misnomer. Similar words in common usage, such as neurosurgery, neurophysiology and neuroanatomy, naturally lead to the assumption that "neuro" in neuropsychiatry stands for "neurologic." But this is not the case. There is no such thing as neurologic psychiatry. Neither can "neuro" stand for nerve or neuron – as in neuromuscular. 'Neuro" is apparently supposed to be an abbreviation of "neurology." If so the term neuropsychiatry is awkward because the endings of the two words are not the same. One rightly abbreviates otology, rhinology and laryngology to otorhinolaryngology, since in this case all endings are the same. If neuropsychiatry is intended to mean an abbreviation of neurology and psychiatry, both of these two words should be used. Each of these disciplines is so large that each deserves to be called by its own full name. One does not say "gynecoobstetrics," but gynecology and obstetrics. One does not say "ophthalmosurgery" when one means ophthalmology and surgery. A laudable effort to do away with the term "neuropsychiatry" was made at the meeting of the Section on Neuropsychiatry of the California State Medical Association in April 1948. A resolution was adopted to suggest to the council that the name of the section be changed from neuropsychiatry to neurology and psychiatry. A further innovation worthy of imitation has been made in this section under the able chairmanship of Dr. Robert B. Aird of San Francisco. In 1948 the section of neuropsychiatry had two separate sessions, held on separate days: one a psychiatric session, the other a neurology session. This is a better arrangement by far than a program of intermingled papers on neurologic and psychiatric subjects. The interests of neurologists and psychiatrists are drifting too far apart to make a constant mixed program appealing to both. The ideal solution for medical societies, of course, would be the establishment of a separate section on neurology and neurosurgery on one side, and a section on psychiatry on the other. But, for the time being, this idea must remain only the pious wish of some neurologists and neurosurgeons.

ROBERT WARTENBURG, M.D., San Francisco.

AUGMENTATION OF MERCURIAL DIRURESIS BY RECUMBENCY

To the Editor:--In connection with the résumé on diuretics by Dr. De Graff (THE JOURNAL, April 17, p. 1025) attention may be called to a simple and useful expedient to enhance the diuretic effect of mercurial compounds, namely, that the patient rest in the recumbent position for eight to twelve hours following administration of the drug.

Newer physiologic investigations are providing clearer insight into the mechanism of congestive heart failure and a better rationale for therapeutic procedures whose value has long been recognized. The beneficent effect of bed rest in cardiac decompensation is due not only to decreasing the work of the heart but in important measure as well to an improvement in the renal circulation. The studies of Warren and Stead (*Arch. Int. Med.* 73: 138, 1944) and others have shown a striking decrease in renal blood flow and glomerular filtration in cardiac failure, with the consequent retention of sodium, a prime factor in the development of edema. The erect position and exercise similarly cause renal vasoconstriction decreasing renal blood flow and glomerular filtration with a fall in diuresis; and particularly is this so in subjects with cardiac failure (Brun, C.; Knudsen, E. O. E., and Raaschou, F.: *Acta med. Scandinav.* 122:315, 1945; Merrill, A., and Cargill, W.H.: *J. Clin. Investigation* 27:272, 1948). The diuretic action of mercury, depending as it does on paralysis of tubular reabsorption of sodium, requires that adequate amounts of sodium and fluid be present in the glomerular filtrate, i.e., an ample renal blood flow and glomerular filtrate. In persons with severe congestive failure who are unresponsive to mercurial diuretics, an increase in renal blood flow brought about by intravenous administration of aminophylline restores the full diuretic effect of mercurials (Weston, R.E., and Escher, D.J.W. in Proceedings Annual Meeting Americal Society for Clinical Investigation, May 3, 1948). The diuretic effect of digitalis in congestive failure likewise is attributable to an increase in cardiac output and renal blood flow. Measures which increase renal blood flow such as bed rest, the xanthines and digitalis genuinely potentiate the diuretic effect of mercurial compounds.

It is customary to administer mercurial diuretics in the morning so that the patient's sleep is not disturbed due to the necessity for frequent voiding. Ambulant patients treated in the office or clinic should be advised to remain in bed on the day they receive a mercurial injection, so that their diuresis is augmented by the increase in renal blood flow and glomerular filtration resulting from recumbency. In subjects on daily or near daily maintenance dosage of mercurial tablets it is preferable that these be taken at bedtime, since in such circumstances of continued mercurial administration diuresis is seldom sufficiently severe to cause much interference with sleep. An additional advantage is served if mercurial tablets are taken at bedtime, for the nocturnal diuresis helps to minimize the increase in blood volume which occurs when edematous subjects assume the recumbent position and reabsorb into the circulation fluid filtered during the day into the extravascular tissues of the lower extremities. It is this increase in blood volume which is responsible for nocturnal dyspnea. Administration of mercurial tablets on retiring, alone or together with a 0.5 Gm. aminophylline suppository, is effective in decreasing nocturnal dyspnea and in aiding the subject with cardiac decompensation to maintain a normal renal excretion of salt and water.

RICHARD GUBNER, M.D., Brooklyn.

Bureau of Investigation

COURT CALLS KAADTS DISGRACE TO PROFESSION

Sentenced For Violation Of Pure Foods Laws

On April 14, 1948, the Federal District Court jury at Fort Wayne, Ind., found the brothers Charles F. Kaadt and Peter S. Kaadt, doing business as the Kaadt Diabetic Clinic at South Whitley, Ind., and Robert Benson, their superintendent, guilty of violation of the Federal Food, Drug and Cosmetic Act. The defendants had, the jury found, caused to be introduced into interstate commerce a drug misbranded by collateral literature. The drug was vinegar and saltpeter (potassium nitrate). The collateral literature created an impression in the mind of the reader that such drug was a specific for diabetes.

On May 4, 1948, twenty days later, the court reconvened to hear arguments on the motion for a new trial by defense attorneys and to pass sentence. For the brothers Kaadt the court assessed the maximum penalty provided in the statute, namely, one year in jail and a fine of $1,000 for each of the seven counts. It was provided that as to counts 1, 2 and 3 of the indictment each defendant would serve the years consecutively, but counts 5, 6 and 7 were to be served concurrently with count 4, on which sentence was suspended. In addition, the brothers were to be placed on probation for an unstated period, to begin at the end of the serving of the sentence. Assessed equally against each of these defendants were costs which totaled approximately $4,300. Defendant Robert Benson received a suspended sentence of one year. He was fined $50 on each of the seven counts, or a total of $350. He was placed on probation for a period of two years. Peter Kaadt was given ninety days within which to begin serving his sentence. He was brought into the courtroom on a stretcher, because of a heart attack. Charles Kaadt was given ten days within which to begin serving his sentence. Both were denied bond pending appeal.

In sentencing the defendants District Judge Patrick T. Stone said:

> It has taken years of effort on the part of the United States Attorney and the Food and Drug Department to bring you to the bar of justice to answer for your crimes. The proof submitted to the jury as to your guilt was overwhelming. For many years you have been engaged, on a wide scale, in a sordid, an evil and a vicious enterprise, without the slightest regard or consideration for the patients that consulted you seeking relief from diabetes. They were innocent and hopeful, but so gullible. They poured out to you their savings, hoping and believing that you would cure them of their ailment. At all times that you operated your institute, you knew there was no cure for diabetes, that the only recognized treatment for this disease was insulin and a sugar-free diet. Yet, notwithstanding that knowledge, you, in your avarice and greed for wealth, wrongfully advised these trustful patients, and as a result they suffered permanent damage and injury, and perhaps some went to an early grave. You have brought disrepute to your profession, disgrace and dishonor to you and your family. Defendant Charles Kaadt has been operating this health-destroying institute for about ten years. The wheels of justice grind slowly but surely. If you defendants were younger, I would not hesitate to impose the maximum sentences of imprisonment. I shall give to you what you withheld from your patients - some consideration for your condition of health. You were cold, cruel, vicious and heartless in your quest for wealth.

The trial, which lasted for seven days, contained much of the dramatic in the parade of injured witnesses or their survivors and in the testimony of expert medical witnesses. The highlight, however, was the cross examination of Dr. Peter S. Kaadt, who was forced to admit that an insulin deficiency exists in diabetes; that vinegar and potassium nitrate would not produce insulin in the body or bring a patient out of a coma; that he did not know how to make a blood sugar or a dextrose tolerance test, nor could he undertake the determination of a blood level of potassium; nor did he know what the renal threshold is, or what constitutes renal glycosuria. Although on direct examination he had described himself as an expert in diabetes, he had to admit that he took the patients' word for their ailments, that he made no physical examinations and that employees of the Kaadt Diabetic Clinic had prepared the patients' histories. Further, no prescriptions or records of medication were kept.

Dr. Kaadt had testified on direct examination that vinegar had therapeutic value in diabetes, but he admitted to previous testimony before a board of medical examiners that it was a vehicle only. His direct testimony on several other important items was similarly impeached.

The ferric chloride test, "given" the patient with the $30 "treatment," which included some digestive tablets and emodin-bearing pills, was shown to be a test for acidosis and therefore useless as a test for sugar in the urine. That patients should be so misled was forcefully brought to the jury's attention.

Charles F. Kaadt, the prime mover of the scheme, did not take the stand in his defense, nor had he appealed the action of the Indiana Board in revoking his license to practice medicine in Indiana in 1947 for gross immorality in his practice.

The court had permitted the reading into the record part of the proceedings before the Board of Medical Registration and Examination wherein Peter Kaadt's license to practice medicine was revoked for gross immorality in the practice of medicine. Further deliberation by the Court, however, resulted in the request that the jury disregard the recitation. Reference, of course, was to the successful action of the Indiana State Board of Medical Registration and Examination which only recently had been upheld by the State Supreme Court.

On his direct examination, Dr. Peter Kaadt in attempting to show that he was only helping his brother thereby permitted the government to introduce a series of letters on the letterhead of the clinic showing his name. These letters revealed, incidentally, that the quantity of vinegar being purchased monthly amounted to eighteen 50 gallon barrels. The prosecuting attorney's summation recalled testimony that the patients were usually kept in the Clinic for three days at $10 a day and that the medicine was sold for $30 a gallon. The added ingredients, principally potassium nitrate, brought the volume to approximately 1,200 gallons of medicine a month. Thus they were able to demonstrate to the jury an approximate monthly gross income of $60,000.

Expert witnesses for the government were Dr. Elliott P. Joslin, emeritus clinical professor of medicine at Harvard University, Dr. Henry T. Ricketts of the University of Chicago, Dr. John Warvel of the University of Indiana, Dr. Joseph Barach of the University of Pittsburgh and past president of the American Diabetes Association, Dr. Rollo N. Harger, professor and head of the Department of Pharmacology and Toxicology of the University of Indiana and state toxicologist, and Dr. William M. LeFevre, internist of Muskegon, Mich.

The story of insulin therapy with diet and of what such has done for the life expectancy of the diabetic person, particularly in the younger age groups, was brought forcibly and dramatically to the attention of the jury. Dr. Joslin recalled having starved children to enable them to live a bit longer in the hope that something would be discovered that would be a control or a cure for the disease.

In striking contrast was the medical testimony for the defense, led by H. Ward Quartel, an osteopath from Dayton, Ohio. He testified that he was getting good results on a dozen patients in the use of the Kaadt vinegar and saltpeter. Cross examination brought out, however, that his testimony before the Indiana State Board of Medical Registration and Examination on behalf of the Drs. Kaadt was given at about the same time that he obtained the formula from them. That was six months earlier, and he had been using the Kaadt method for the same length of time.

Quartel was followed by two doctors of medicine. Elmer N. Shockley of Bassetts, Va., house physician in an industrial plant, stated he had 1 diabetic patient on whom the Kaadt treatment had been used. It was brought out on cross examination that he had gone to South Whitley to the Kaadt Diabetic Clinic for treatment of his own diabetes, which was, he stated, improved by the vinegar and saltpeter. He also admitted, on cross examination, conversations with a former employee of the Kaadt Diabetic Clinic with a view to opening a similar institution in the East. Such, however, was not done.

Dr. George L. Thompson of Owensboro, Ky., testified that he brought his wife, a sufferer from diabetes, to the clinic. She did not appear as a witness. Cross examination, however, revealed that Dr. Thompson does treat his own diabetic patients with insulin.

Both sides were limited to the introduction of testimony on six items of fact. Six witnesses appeared on behalf of the government, of whom 3 were younger persons with diabetes, 2 were survivors of deceased diabetic patients and the sixth was an amputee. Testifying for the defense were 6 persons who claimed that they were diabetic and had received benefit from the use of the Kaadt treatment. It so happened that 2 of these had recently been examined by other physicians who came to Fort Wayne to testify in rebuttal for the government. Each of the "satisfied" customers of the Drs. Kaadt had 4 plus sugar.

Perhaps the most damaging witness to the brothers Kaadt was a boy aged 15 who had gone to the Clinic because his mother had heard of the "cure. She had other children at home and could not remain with him at the clinic. This lad took notes of a lecture delivered by Dr. Charles Kaadt (as was clinic custom) and testified from these notes that Dr. Kaadt had told his listeners, among other things, that "whisky is good for diabetes"; "boiled sugar is safe"; "the less insulin the better," and "if you have a diet, throw it away."

The Kaadt Diabetic Clinic has been in operation for a good many years. Dr. Charles F. Kaadt started out in Fort Wayne, Ind., during the twenties. He had been a surgeon for the Wabash Railroad. The Bureau of Investigation reported on the matter in THE JOURNAL of Aug. 15, 1931. The report at that time told of the attempt on the part of the Bureau to learn the details of the treatment, which was then being sold by mail, a quart bottle costing $5. The medicine at that time was described as a material which indicated the presence of potassium nitrate in fairly large amounts, dissolved in a brown, murky liquid having the odor of vinegar. Over the years, the only change seems to have been the increase to gallon lots with digestive and laxative pills as the components of the home treatment also being carried away by the victims. On cross examination Peter Kaadt complained that medical science quit when it discovered insulin.

In the past, adversity, in the form of action denying the use of the mails, which earlier had disrupted active interstate distribution of this nostrum, only served to solidify the business of Dr. Charles Kaadt. When it became so large that he could no longer handle it alone, his brother joined with him.

So for the institution has had the benefit of the investigative action of the Better Business Bureau of Indianapolis, the *Indianapolis Star*, the Indiana State Board of Medical Registration and Examination, the Post Office Department and now the Food and Drug Administration and the Department of Justice. Withal it has taken considerable effort and enormous expense to place the present obstacles in the path of the prosecution of this business. During the trial the institution was being operated under the guidance of Dr. Archie Jones, of Fort Wayne and other Indiana points. Newspapers, during the trial carried a report that he was to be cited by the Indiana State Board of Medical Registration and Examination to show cause why his license to practice medicine should not be revoked. More recent reports do indicate, however, that the Kaadt Diabetic Clinic has finally closed its doors.

The government was ably represented by United States Attorney Alex M. Campbell and his assistants, James S. Keating and Gilmore S. Haynie. The defendants had Frank E. Corbett and Lloyd Hartzler of Fort Wayne as counsel. Congratulations are certainly in order to the office of the United States Attorney for skilful handling of the case in such a manner that a favorable verdict was reached by the jury within a relatively short period of time. The investigation of the Food and Drug Administration as the preliminary to the court action bore such fruit as to indicate its efficiency. It is the hope of the Bureau that these events may serve as discouragement to others who may seek to capitalize on uninformed fear of the insulin needle.

Medical Motion Pictures

FILM REVIEW

Daily Battle. 16 and 35 mm., black and white, sound, 800 feet (one reel), showing time twenty minutes. Produced in 1947 by RKO Pathe, Inc., through the cooperation of McCook Memorial Hospital, Hartford, Conn. Procurable on loan or purchase from the National Foundation for Infantile Paralysis, 120 Broadway, New York 5.

This film is a vivid portrayal of the services provided by the March of Dimes, through national and local chapters of the National Foundation for Infantile Paralysis. It was designed to show how the funds are used in the fight against poliomyelitis and the constant vigil necessary to meet the handling of these cases. The film can be recommended for showing to hospital personnel, physical therapists and those persons interested in rehabilitation problems.

The Feeling of Rejection; Its Development and Growth. 16 mm., black and white, sound, 800 feet (1 reel), showing time twenty minutes. Prepared in 1947 with the technical advice of the Medical staff of the Allen Memorial Institute of Psychiatry, McGill University and the Royal Victoria Hospital, Montreal, for the Mental Health Division of the Department of National Health and Welfare, Ottawa. Produced and procurable on rental or purchase from the National Film Board of Canada, 400 West Madison Street, Chicago 6, and 620 Fifth Avenue, New York 20.

This film portrays the case of Margaret, who at the age of 22 complains to a psychiatrist that she is shy, moody and indecisive to the point of self frustration. Placed on a gynecologic table in lieu of an analytic couch, Margaret recounts the story of her life and thus furnishes the script for a series of flashbacks in familiar Hollywood styles. Margaret's mother is accused of inculcating fears of normal initiative and exploratory play in Margaret's childhood, after which Margaret is shown experiencing rivalry with a younger sibling, feeling rejected by her parents frustrated in substitutive attachments to an idealized school friend and so on. To an experienced analyst these retrospective fantasies can mean little more than literalized "screen memories," yet they are presented in the film as the cause rather than the accompaniment of defensive personality traits such as exaggerated meticulousness, masochistic discipline and resentful isolation.

From a technical point of view the film has a number of other defects: the musical interpolations are distracting and amateurish, and the commentary is occasionally so tedious and pontifical that the net effects are painful rather than poignant.

Psychologically, the film oversimplifies the nature of "feeling of rejection" and fails to clarify the complex sexual inhibitions, repressed hostilities and other unconscious conflicts that underly Margaret's obsessive-compulsive neurosis. Certainly, the implication that such deep seated character deviations can be corrected in a few therapeutic interviews is seriously misleading.

On the favorable side, this is a commendable first attempt to present some of the modern concepts of dynamic psychiatry to lay or ancillary professional groups. Despite the explanatory pamphlet that accompanies the film, however, a competent psychologist or psychiatrist should be present to clarify and amplify its message and so prevent misunderstanding of its content.

The following 16 mm., black and white sound motion pictures are part of a series of five films produced in 1947 by the McGraw-Hill Book Company for correlation with the Textbook of Healthful Living, prepared by Harold S. Diehl, M.D., dean of the medical sciences, University of Minnesota, Minneapolis. Procurable on purchase from McGraw-Hill Book Company, Inc., 330 West Forty-second Street, New York 18, or procurable on rental from Y.M.C.A. Motion Picture Bureau, 19 South La Salle Street, Chicago 3.

Emotional Health. 725 feet (one reel), showing time twenty minutes.

The continuity of this motion picture is characterized by excellent writing, competent acting and good medical sense. A youth consults a general practitioner for "heart trouble" and receives the usual diagnostic examination. He is told that he is in normal physical condition but that his cardiac symptoms may be due to *functional disturbances arising from emotional* stresses. The physician's explanations, clear and concise in themselves, are illustrated by sequences of action and cartoon animation which, though somewhat oversimplified, would be illuminating to a lay audience. The youth is then advised to consult a psychiatrist, and his objections to the referral are dispelled by further reassurances that could serve as a model for many a practitioner. Excerpts from several of the patient's subsequent interviews with the psychiatrist--for once portrayed as a perceptive and rational human being--are then recorded, and the patient's anxieties are traced to conflictful familial, sexual and social attitudes. Throughout this section of the film typical episodes that may have led to the formation of disturbing unconscious conflicts are recalled in vivid flashbacks relevant to the patient's childhood experiences. Although the interviews are of necessity somewhat telescoped, the course of the therapy is presented in logical and convincing sequence and with a validity that stems from authoritative supervision.

This film can be highly recommended not only for the teaching of medical undergraduates but for presentation to lay groups interested in some of the principles of psychosomatic medicine and *brief psychotherapy*.

Body Care and Grooming. 600 feet (one reel), showing time sixteen minutes.

The importance of personal cleanliness, good grooming and proper attention to clothing is well depicted in this film in a way that would be acceptable to the average college student. The structure and activity of the skin are shown in diagrammatic animation. The motivation for cleanliness and care of the body is extremely effective, and, though it is particularly aimed at students of college age, there is no apparent reason why it would not be equally useful for high school groups. It could be used in mixed as well as in segragrated groups.

A silent follow-up film strip, consisting of scenes selected from the corresponding motion picture over which questions are superimposed, accompanies each motion picture. Photography is excellent and the animation is well done.

The following was omitted from the motion picture review entitled "HUMAN REPRODUCTION" which appeared in THE JOURNAL, A.M.A., May, 1948, p. 323:

The following 16 mm., black and white sound motion picture is a part of a series of five films produced in 1947 by the McGraw-Hill Book Company for correlation with the Textbook of Healthful Living, prepared by Harold S. Diehl, M.D., Dean of the Medical Sciences, University of Minnesota, Minneapolis. Procurable on purchase from McGraw-Hill Book Company, Inc., 330 West Forty-second Street, New York 18, or procurable on rental from Y.M.C.A. Motion Picture Bureau, 19 South La Salle Street, Chicago 3.

An Introduction To Extracellular Fluid. 16 mm., black and white, sound, 800 feet (one reel), showing time twenty-five minutes. Prepared in 1945 by James L. Gamble, M.D., professor of pediatrics, Harvard University Medical School, Boston. Produced by and procurable on loan from Mead Johnson & Company, Evansville 21, Ind.

The author presents a lecture based on a highly technical subject to which he has devoted much time and effort over a period of years. The chemistry and physiology of extracellular fluid have been his chief medical interest, together with the application of basic principles to the clinical aspects of fluid balance in health and disease. This picture will be of interest to those who studied under the author and to those interested in fluid balance, However, to those who are looking for a teaching film containing the modern devices, this picture will be a disappointment because it shows the self-effacing scientist, rather ill at ease before the sound camera, presenting his subject in lecture form with the aid of two charts. It might have been preferable to portray the author in his laboratory, at his desk or in the ward in lieu of standing before an unseen group of students.

Coming Medical Meetings

American Medical Association, Chicago, June 21-25. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Aero Medical Association, Royal York Hotel, Toronto, Canada, June 16-18. Dr. Thomas H. Sutherland, 214 S. State St., Marion, Ohio, Secretary.

American Academy for Cerebral Palsy, Baltimore, May 30-31. Dr. Meyer A. Perlstein, 4743 N. Drake Ave., Chicago 25, Secretary.

American Academy of Tuberculosis Physicians, Chicago, June 19. Dr. Oscar S. Levin, P. O. Box 7011, Denver 5,

American Association for the Surgery of Trauma, Drake Hotel, Chicago, June 17-20. Dr. Charles G. Johnston, 1512 St. Antoine St., Detroit 26, Secretary.

American Association for Thoracic Surgery, Quebec, Canada, May 31-June 2. Dr. Brian Blades, 1335 H St. N.W., Washington 5, D.C., Secretary.

American Association of the History of Medicine, Penn Sheraton Hotel, Philadelphia, May 26-27. Dr. Howard Dittrick, 2020 E. 93rd St., Cleveland 6, Secretary.

American Blood Irradiation Society, Stevens Hotel, Chicago, June 19-20. Dr. G. J. P. Barger, 1125 Buchanan St. N.W., Washington, D.C., Secretary.

American College of Chest Physicians, Congress Hotel, Chicago, June 17-20. Dr. Benjamin L. Brock, 500 N. Dearborn St., Chicago 10, Secretary.

American College of Radiology, Sheraton Hotel, Chicago, June 20. Mr. Mac F. Cahal, 20 N. Wacker Drive, Chicago 6, Executive Secretary.

American Diabetes Association, Chicago, June 17-20. Dr. George E. Anderson, 429 Clinton Avenue, Brooklyn 5, Secretary.

American Electroencephalographic Society, Claridge Hotel, Atlantic City, June 12-13. Dr. Robert S. Schwab, Massachusetts General Hospital, Boston 15, Secretary.

American Heart Association, Stevens Hotel, Chicago, June 18-19. Dr. Harry E. Ungerleider, 50 W. 50th St., New York, Secretary.

American Medical Women's Association, Blackstone Hotel, Chicago, June 19-20. Dr. Helena T. Ratterman, 125 Wm. Taft Road, Cincinnati 19, Corresponding Secretary.

American Neurological Association, Claridge Hotel, Atlantic City, June 14-15. Dr. H. Houston Merritt, 100 E. Gun Hill Road, New York 67, Secretary.

American Orthopedic Association, Quebec, Canada, June 3-6. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Otorhinologic Society for the Advancement of Plastic and Reconstructive Surgery, Academy of Medicine Bldg., New York, June 10. Dr. Norman N. Smith, 291 Whitney Ave., New Haven 11, Conn., Secretary.

International Poliomyelitis Conference, Waldorf-Astoria Hotel, New York, July 12-17. Mr. Stanley E. Henwood, Room 571, Waldorf-Astoria Hotel, New York 22, Executive Secretary.

Maine Medical Association, Poland Spring House, Poland Spring, June 20. Dr. Frederick R. Carter, 142 High St., Portland 3, Secretary.

Massachusetts Medical Society, Hotel Statler, Boston, May 25-27. Dr. H. Quimby Gallupe, 8 Fenway, Boston 15, Secretary.

Medical Library Association, Warwick Hotel, Philadelphia, May 28-30. Miss M. Edna Poole, 288 Bloor St. W., Toronto 5, Canada, Secretary.

Minnesota State Medical Association, Minneapolis, June 7-9. Dr. B. B. Souster, 496 Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Montana, Medical Association of, Billings, June 17-19. Dr. H. T. Caraway, 115 N. 28th St., Billings, Secretary.

National Gastroenterological Association, Hotel Pennsylvania, New York, June 7-10. Dr. G. Randolph Manning, 1819 Braodway, New York 23, Secretary.

National Tuberculosis Association, Hotel Pennsylvania, New York, June 14-18. Dr. H. Stuart Willis, 1790 Broadway, New York 19, Secretary.

New Hampshire Medical Society, Newcastle, June 2-3. Dr. Carleton R. Metcalf, 5 S. State St., Concord, Secretary.

New Mexico Medical Society, Las Vegas, June 3-5. Dr. H.L. January, 221 W. Central Ave., Albuquerque, Secretary.

North Dakota State Medical Association, Jamestown, May 23-25. Dr. O. A. Sedlak, 702 First Avenue S., Fargo, Secretary.

Society for Investigative Dermatology, Hotel Sherman, Chicago, June 20. Dr. Samuel M. Peck, 140 E. 54th St., New York 22, Secretary.

Society for Vascular Surgery, Hotel Stevens, Chicago, June 20. Dr. J. Ross Veal, 1028 Connecticut Ave., Washington 6, D. C.

South Dakota State Medical Association, Sioux Falls, May 30-June 1. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Southern Society of Clinical Surgeons, Chicago, May 26-28. Dr. William P. Nicolson Jr., 478 Peachtree St. N. E., Atlanta, Ga., Secretary.

American Pediatric Society, Quebec, Canada, May 24-26. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiotherapy Association, La Salle Hotel, Chicago, May 23-28. Miss Mildred Elson, 1790 Broadway, New York 19, Executive Secretary.

American Proctologic Society, Chicago, June 18-21. Dr. Vernon G. Jeurink, 1612 Tremont Place, Denver 2, Secretary.

American Radium Society, Hotel Stevens, Chicago, June 20. Dr. Hugh F. Hare, 605 Commonwealth Ave., Boston 15, Secretary.

American Rheumatism Association, Hotel Stevens, Chicago, June 19-20. Dr. Charles Ragan, 620 W. 168th St., New York 32, Secretary.

American Surgical Association, Chateau Frontenac, Quebec, Canada, May 27-29. Dr. Warfield M. Firor, Johns Hopkins Hospital, Baltimore 5, Secretary.

American Therapeutic Society, Chicago, June 29. Dr. Oscar B. Hunter, 1835 I St. N.W., Washington 6, D. C., Secretary.

American Venereal Disease Association, Chicago, June 20. Dr. William L. Fleming, 750 Harrison Ave., Boston, Secretary.

Association for the Study of Internal Secretions, Palmer House, Chicago, June 18-19. Dr. Henry H. Turner, 1200 N. Walker St., Oklahoma City 3, Secretary.

Idaho State Medical Association, Sun Valley, July 5-8. Dr. Wallace Bond, 144 E. Fourth Ave., Twin Falls, Secretary.

Interamerican Cardiological Congress, Michael Reese Hospital, Chicago, June 13-17. Dr. Richard Langendorf, Michael Reese Hospital, 29th and Ellis, Chicago 16, Secretary.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and the Examining Boards in Specialties were published in THE JOURNAL, April 17, page 1064.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Examination. Montgomery, June 22-24, 1948. Sec., Dr. D.G. Gill, 519 Dexter Ave., Montgomery 4.

ARKANSAS:* Examination. Little Rock, June 3-4. Sec., Medical Board of the Arkansas Medical Society, Dr. L.J. Kosminsky, Texarkana. Eclectic: Little Rock, June 3. Sec., Dr. C.H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral. San Francisco, June 5-6; Los Angeles, Aug. 7-8. Written Examination. San Francisco, June 7-10. Los Angeles, Aug. 9-12. Oral and Clinical Examination for Foreign Graduates. San Francisco, June 6. Sec., Dr. Frederick N. Scatena, 1020 N. Street, Sacramento 14.

COLORADO:* Examination. Denver, June 21-23. Final date for filing application is June 5. Sec., Dr. J.B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT:* Examination. Hartford, July 6-7. Sec., Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: Examination. Dover, July 13. Endorsement. Dover, July 22. Sec., Dr. J.S. McDaniel, 229 S. State St., Dover.

FLORIDA:* Examination. Jacksonville, June 29-30. Sec., Dr. Harold D. Van Schaick, 6675 Windsor Lane, La Gorce Island, Miami Beach 41.

GEORGIA: Examination. Atlanta, June 8-9. Endorsement. June 10. Sec., Mr. R.C. Coleman, 111 State Capitol, Atlanta.

HAWAII: Examination. Honolulu. July 12-15. Sec., Dr. S.E. Doolittle, 881 S. Hotel St., Honolulu.

IDAHO: Boise, July 13-15. Sec., Bureau of Occupational Licenses, Miss Estella S. Mulliner, 355 State House, Boise.

ILLINOIS: Chicago, June 29-July 1. Supt., Dept. of Registration and Education, Mr. Fred W. Ruegg, Springfield.

INDIANA: Examination. Indianapolis, June 15-17, 1948. Sec., Board of Medical Registration and Examination, Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

KANSAS: Kansas City, June 9-10. Sec., Board of Medical Registration & Examination, Dr. J.F. Hassig, 905 N. 7th St., Kansas City.

KENTUCKY: Examination. Louisville, June 16-18. Sec., Dr. P.E. Blackerby, 620 S. 3rd St., Louisville.

LOUISIANA: New Orleans, June 3-5. Sec.-Treas., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MAINE: Augusta, July 6-7, Sec., Dr. A.P. Leighton, 192 State Street, Portland.

MARYLAND: Medical Examination. Baltimore, June 15-18. Sec.-Treas., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. Homeopathic Examination. Baltimore, June 15-16. Sec., Dr. J.A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Examination. Boston, July 13-16. Sec., Board of Registration in Medicine. Dr. H.Q. Gallupe, 413-E. State House, Boston.

MICHIGAN:* Examination. Parlor A, Olds Hotel, Lansing, June 9-11. Sec., Board of Registration in Medicine, Dr. J.E. McIntyre, 100 W. Allegan St., Lansing.

MISSISSIPPI: Jackson, June 28-29, 1948. Asst. Sec., State Board of Health, Dr. R.N. Whitfield, Jackson,

MONTANA: Helena, Oct. 4-6. Sec., Dr. O.G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA:* Examination. Omaha, June 7-9. Dir., Mr. Oscar F. Humble; Room 1009 State Capitol Bldg., Lincoln 9.

NEW HAMPSHIRE: Concord, Sept. 9. Sec., Board of Registration in Medicine, Dr. J.S. Wheeler, Room 107, State House, Concord.

NEW JERSEY: Examination. Trenton, June 15-17. Sec., Dr. E.S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO:* Santa Fe, Oct. 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

NEW YORK: Examination. Various Centers, June 28-July 1. Sec., Dr. J.L. Lochner Jr., State Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G.M. Williamson, 4½ S. 3rd St., Grand Forks.

OHIO: Examination. Columbus, June 21-24. Sec., Dr. H.M. Platter, 21 W. Broad St., Columbus 15.

OKLAHOMA:* Oklahoma City, June 2-3. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON:* Examination. July and Jan. Endorsement. July and Aug. Sec., Miss L.M. Conlee, 608 Failing Bldg., Portland.

PENNSYLVANIA: Examination. Philadelphia & Pittsburgh, July. Act. Sec., Bureau of Professional Licensing, Mrs. M.G. Steiner, 351 Education Bldg., Harrisburg.

RHODE ISLAND:* Examination. Providence, July 1-2. Chief, Div. of Professional Regulation, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Written Examination. Columbia, June 21-23. Endorsement. July 5. Sec., Dr. N.B. Heyward, 1329 Blanding St., Columbia.

SOUTH DAKOTA:* Pierre, July 20-21. Sec., Dr. Gilbert Cottam, Capitol Bldg., Pierre.

TENNESSEE:* Examination. Memphis & Nashville, June 9-10. Sec., Dr. H.W. Qualls, 1635 Exchange Bldg., Memphis.

TEXAS: Waco, June 16-18. Sec., Dr. H.F. Connally, 1305 Amicable Bldg., Waco.

UTAH: Examination. Salt Lake City, June, 1948. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: Examination. Burlington, June 25-26. Sec., Dr. F.J. Lawliss, Richford.

VIRGINIA: Examination. Richmond, June 18-19. Endorsement. Richmond. June 17. Sec., Dr. K.D. Graves, 306 Medical Arts Bldg., Roanoke.

WEST VIRGINIA: Charleston, July 5-7. Comm., Public Health Council, Dr. N.H. Dyer, State Capitol Bldg., Charleston.

WISCONSIN:* Milwaukee, June 29-July 1. Sec., Dr. C.A. Dawson, Tremont Bldg., River Falls.

WYOMING: Examination. Cheyenne, June 7. Sec., Dr. G.M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: Examination. Tucson, June 15. Sec., Mr. Francis A. Roy, Univ. of Arizona, Tucson.

COLORADO: Examination. Denver, June 2-3. Sec., Dr. E. B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: Examination. June 12., Exec. Asst., State Board of Healing Arts, Mr. W.G. Reynolds, 110 Whitney Ave., New Haven 10.

IOWA: Des Moines, July 13, Oct. 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MINNESOTA: Examination. Minneapolis, June 1-2. Sec., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

OREGON: Examination. Portland, June 19. Final date for filing application is June 2. Sec., Basic Science Examining Committee, Dr. C.D. Byrne, Univ. of Oregon, Eugene.

SOUTH DAKOTA: Examination. Vermillion. June 4-5. Sec., Dr. G.M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Examination. Memphis, July 5-6. Sec., Dr. O.W. Hyman, 874 Union Ave., Memphis.

WISCONSIN: Examination. Madison, Sept. 25. Final date for filing application is Sept. 18. Sec., Prof. W.H. Barber, Scott & Watson Sts., Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Narcotics: Physician's Right to Possess Narcotics Unlawfully Obtained.—The defendant was convicted of unlawfully possessing a narcotic drug and from such conviction appealed to the court of criminal appeals of Texas.

A patient of the defendant physician testified that his wife was given a prescription calling for fifteen tablets of 1/16 grain (4 mg.) "Dilaudid Hcl" (dihydromorphinone hydrochloride) which was taken to a pharmacist and properly filled. The patient then returned to the physician's office and gave him the box which the pharmacist had given her. He took it into his private office. A little while later he delivered to the patient a box of pills which were subsequently analyzed as "novocaine" hydrochloride and not "dilaudid" hydrochloride. "Novocaine" hydrochloride is not a derivative of opium, but "dilaudid" hydrochloride is. It was the contention of the state that the defendant physician came into possession of the narcotic by taking the same from the filled prescription and substituting another drug therefor--in other words, that the defendant acquired the narcotic by theft, subterfuge or fraud and that therefore his possession of it was unlawful. The defendant contended that he had the right to possess narcotics.

Section 2 of the uniform narcotic act provides that "It shall be unlawful for any person to... possess...any narcotic drug." Section 2 A provides that: "It shall not be unlawful to...possess... any narcotic drug where same is authorized under the terms of this Act." These two sections, 2 and 2 A, said the court, are a part of the same act and are of equal dignity. They must therefore be construed together. When so construed, they must mean that if the act authorizes possession of a narcotic, such possession is lawful; otherwise, it is not. It becomes material, then, the court continued, to determine wherein the act authorizes possession of a narcotic and if the defendant has discharged the burden resting upon him to bring himself within those provisions. A physician--that is, one authorized by law to practice medicine--in this state may in good faith, in the course of his professional practice only, prescribe, administer and dispense narcotic drugs. The term dispense as there used, in addition to its ordinary meaning, includes "distribute, leave with, give away, dispose of or deliver." The terms prescribe and administer--not being specially defined--are used in their ordinary meaning, as commonly known and understood. So, then, a physician may in the course of his professional practice prescribe, administer, dispense, distribute, leave with, give away or deliver a narcotic. The right to do these things carries with it the right to possess, because possession is first necessary and without it such rights could not be fully exercised. The term possession, as here used, means the actual care, control and management of the narcotic.

If we understand the state's position, said the court of criminal appeals, it is that since there are facts sufficient to show that the defendant came into the possession of the narcotic by unlawful means, he could not thereafter be in the lawful possession thereof. To accept this theory would require, by judicial construction, writing into the act an additional limitation not found therein--which would be that unless and until a physician came into possession of a narcotic by lawful means, he could not make use of the same in any manner. The act authorized the physician to make unlimited use of the narcotic in the particulars mentioned. We would not be authorized, said the court, by judicial construction, to place a limitation on that right not found in the act. In the light of what has been said, there appears no escape from the conclusion that, under the rights expressly conferred under the act, it is not unlawful for the physician duly licensed by the laws of this state to have in his possession, or possess, narcotic drugs. Since the defendant was a duly licensed practitioner of medicine in this state, his conviction for possessing a narcotic drug is accordingly reversed.—*De Vine v. State, 206 S. W. (2d) 247 (Texas, 1947).*

Blood Grouping Tests: Admissibility in Evidence over Objection of Self Incrimination.—The defendant was found guilty of murder in the first degree and appealed to the Court of Appeals of Maryland.

At the time of the defendant's arrest, he was in a hospital under treatment for iodine poisoning and after being placed in jail he was treated by the county medical officer. The following day another physician visited him, at the request of the state's attorney, for the purpose of getting a sample of his blood. The physician testified that the captain of detectives, who accompanied him on the visit, asked the defendant if he would mind if he took his blood. The defendant held out his arm, the physician took some of his blood and turned the specimen over to the officer. The physician also testified that he listened to the defendant's heart and took his pulse, but did not tell him why he wanted the blood other than that the state's attorney requested it. The captain of detectives corroborated this testimony and said that, in addition, the physician asked if the medicine the county physician had given him the previous night had worked. He too stated that when he asked the defendant if he had any objection to their getting a sample of his blood, the defendant said no and held up his arm, to the physician. The defendant was not informed of the purpose for which they wanted the blood specimen. The defendant testified that the physician asked him if he knew that the iodine he had taken might affect his eyes or his kidneys and said that he would like to take a blood test and a urine specimen. The defendant said he thought they were doing it for his health.

On appeal the defendant contended that the admission of testimony about his blood, taken from his body by a subterfuge, was a violation of his constitutional immunity from giving evidence against himself. We are unable to see where there is any constitutional question involved in this case, the Court of Appeals concluded. There is no substantial difference between obtaining a specimen of blood from an accused and obtaining his fingerprints or physical property, the possession of which by him is a pertinent question at issue in a felony against him. Whatever may be the rule in other jurisdictions we have long since adopted the rule that the admission of evidence thus obtained is not a violation of the Maryland Declaration of Rights, and we so hold in this case. Accordingly the judgment of conviction was affirmed.--*Davis v. State 57 A. (2d) 289 (Md., 1948).*

Extravagant Claims and Promotional Literature as Misbranding.--The defendant was charged with a violation of the federal food, drug and cosmetic act for introducing misbranded drugs into interstate commerce. From a judgment of conviction, the defendant appealed to the circuit court of appeals, seventh circuit.

Section 301 of the food and drug act prohibits the introduction or delivery for introduction into interstate commerce of any drug that is misbranded; section 502 provides that a drug shall be deemed to be misbranded if its labeling is false or misleading in any particular, and section 201 (*m*) defines the term " labeling " to include all labels and other written, printed or graphic matter accompanying such article.

The defendant was a self-styled authority on nutrition and vitamins. Operating under various trade names, he had been producing and marketing his products since January 1941, largely through " health food " stores. The products appear to be, for the most part, compounded of various vitamins, minerals and herbs. No charge of falsehood was made as to the principal labels printed on the packages in which each product was contained. The misbranding charged was contained in a number of printed pamphlets and circulars, and one display placard. The mode of distribution of this literature differed. In some cases it was contained in the carton in which the articles were shipped. More often, it was separately shipped to the same consignees, and in at least one case a period of a year and a half intervened between the shipment of the product and the literature, respectively.

In order to support a misbranding charge, said the court, it is not necessary that the matter alleged to accompany the product be shipped in the same container or even that it be shipped simultaneously. The defendant contended that the literature here involved was not only not shipped in the same carton with the products in all cases, but neither was it intended by him that product and literature should be placed together by the dealer to whom they were sent. His theory was that the literature was intended for advertising, not labeling. All the printed matter, he said, was intended either to be mailed out or to be sold, as indicated by the fact that with the exception of the one display placard, each piece either contained a price mark or a mailing permit with space for address. This showed he contended, that product and literature were not to be distributed together, hence could not be said to accompany each other.

First, said the court, labeling and advertising are not mutually exclusive and the same matter may serve both purposes. Second, the placing of the mailing permit or the price tag on the literature cannot insulate the defendant from liability for introducing the drugs and their related descriptive matter into interstate commerce together by consignment to the same consignee for distribution by him.

The test, the court continued, is not of physical contiguity but of textual relationship. Viewed thus, the products and literature here involved were interdependent because the former lacked the labeling necessary to inform the purchasing public of of their uses and purposes. The labels printed on the immediate containers did not indicate the purposes for which the articles were to be used. The literature was intended and essential to explain the alleged uses of the products. It constituted a supplement to the label physically attached to the container of the product. One of the health food dealers in whose store the " kordel " products were sold admitted that if he were buying one of the products he would have to go to " reliable sources" to know to what use to put the product. Presumably, said the court, those reliable sources were the booklets displayed in racks close by the counter where the drugs were dispensed or lying on the counter where they were available to the public and could be picked up and examined. Some also were wrapped with merchandise or handed to customers. Because the literature was shipped by the defendant or at his order to the same consignees as the products, was related to those products, and was intended for distribution in relation to them, it did accompany the products into interstate commerce within the definition of the act.

With respect to the misrepresentations contained in the accompanying literature, said the circuit court of appeals, we think there can be no serious question. The two booklets, " Nutrition Guide " and " What You Can Do About Relieving the Agonies of Arthritis," were written by defendant, who in the latter is described as "America's leading vitamin and diet expert." " Health Today, Spring 1945," is edited by the same " famous nutrition and vitamin authority." While all purport to be scientific publications of general interest apart from the articles produced and marketed by the defendant, all are replete with references to the " kordel " products and their uses to prevent, ameliorate or cure a vast and diverse variety of ailments, and each conveniently closes with a price list of the various " kordel " products recommended for use therein. All are concerned primarily with promoting the sale of the various products by explaining the need for each, along with extravagant claims as to the usefulness of each. A study of the three pamphlets reveals that the products therein described are recommended for relieving stomach agonies, general weakness, anemia, premature old age, high blood pressure, liver troubles, failing eyesight and sore feet; for maintaining blood energy, muscular activity, sound teeth and gums, healthy skin, hair and eyes, normal functioning of the pituitary and thyroid glands, stomach, intestines, colon, liver and kidneys, and for preventing arthritis and stiff joints, excess weight, catarrh, nervous breakdown, sterility and paralysis. Thus the scheme devised by the defendant for the distribution of his products and related literature contemplates an elaborate system of self diagnosis and medication. The government introduced the evidence of many eminent men in the medical profession to prove the dangerously misleading character of the literature in that the drugs were useless to combat the conditions they were represented to relieve, while delay in correct diagnosis and treatment for those conditions might render treatment useless. All the experts were agreed that, although the claims were absurd and fantastic, they were dangerous in that they tended to lull persons into a false sense of security in reliance on the drugs when they might need professional diagnosis and treatment for conditions which might respond to treatment if correctly diagnosed early enough, but which might become much more serious if not taken care of early. Since the literature, which we have already held accompanied the products, embodies such misleading representations, the court of appeal concluded, it constitutes misbranding within the meaning of the act. Accordingly the conviction of the defendant was affirmed.--*United States v. Kordel, 164 F. (2d) 913 (1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

Carcinoma of Colon Secondary to Chronic Ulcerative Colitis. T. M. Johnson and T. G. Orr.—p. 21.
*Importance of Occult Blood in Stool. W. D. Paul and H. E. Hamilton.—p. 23.

Occult Blood in the Stool.—Paul and Hamilton believe that digital examination of the rectum and the test of a fecal specimen for occult blood should be a routine part of physical examination. Earlier recognition of a disease process in the gastrointestinal tract will be made if this simple and expedient procedure is carried out. A technic employed at the University of Iowa hospitals is as follows: Following the digital examination, the gloved finger is placed over the top of a 3/4 inch (1.91 cm.) test tube containing 5 cc. of water. The tube is shaken so that the adhering stool specimen is washed from the end of the gloved finger, and a drop of this solution is placed on a small piece of filter paper. An orthotolidine tablet is placed on this moistened filter paper and 2 drops of water are permitted to flow over the tablet and down on the filter paper. If occult blood is present, the filter paper about the orthotolidine tablet will turn a blue color of varying intensity within two minutes. Even though there is no visible fecal material adhering to the gloved finger the material obtained will frequently be sufficient to give a positive reaction if the preceding stool specimen contained occult blood.

Radium in Uterus.—Arneson and his associates say that about 1938 the method of radium treatment of uterine cancer was changed in two hospitals in St. Louis. Previously intrauterine treatment had been given by means of tandems containing from two to three tubes in linear arrangement. That applicator did not always meet the standard requirement of active length extending from the level of the external os to the top of the fundus. The first modification, which employed gauze strips to hold multiple tubes in position, did not prove satisfactory. Many technical difficulties were eliminated by a special instrument developed in 1940. By means of an introducer the number of tubes placed within the uterus was increased considerably. Brass capsules of a standard external diameter were obtained for radium sources. Length of capsules varied according to length of the radium tubes, but the strength per centimeter active length was on the order of 5 or 6 mg. of radium. From ten to twelve such capsules can be packed into a uterine cavity of normal size. Capsules of greater external diameter are used in the cervical canal to maintain patency adequate for removal of the intrauterine radium. Stronger sources are used in the cervical capsules. The authors review observations on 93 patients with endometrial cancer treated between 1936 and 1941. Of the entire group, 45 per cent were considered inoperable. The absolute five year survival rate for the 43 patients treated by radiation alone is 27 per cent. For the 32 patients receiving preoperative roentgen and radium therapy followed by hysterectomy the five year result is 68 per cent. Surgery alone was used in 18 patients, of whom 84 per cent remained well for the same period. Explanation of the unusually good results from hysterectomy alone is made on the basis of favorable clinical material. Among patients treated by radiation alone the use of intrauterine tandems resulted in survival of only 22 per cent, but 32 per cent of those irridiated with multiple capsules are well at the end of the five year period. For treatment by radiation and hysterectomy the use of intrauterine tandems resulted in survival of 54 per cent, but the value for multiple capsules of radium is 79 per cent.

Culdoscopy.—TeLinde and Rutledge report their experience with culdoscopy in 56 cases. The patient is placed in the knee-chest posture. The procedure can be carried out under local or general anesthesia. The uterus, tubes, ovaries, broad ligaments, uterosacral ligaments, infundibulopelvic ligaments, rectal wall, sigmoid, small intestines and often the cecum, appendix and even the ureters can be visualized. The culdoscope may be moved from side to side and rotated as necessary. Culdoscopy is indicated particularly to gain more information in cases in which the history and/or pelvic examination suggest tubal pregnancy. Of the 56 cases of culdoscopy reported here, 37 were for this purpose. Ectopic gestation is more often overlooked and more often diagnosed when not present than any other serious pelvic disorder. Salpingitis was found to be the condition simulating tubal gestation in 18 of the 37 cases. The differential diagnosis between salpingitis and endometriosis may at times offer considerable difficulty. The culdoscopic pictures in both conditions are quite characteristic, and the differentiation is easily made unless the cul-de-sac is obliterated by adhesions. In postmenopausal bleeding culdoscopy may detect a nonpalpable ovarian or tubal neoplasm. In certain endocrine disturbances, such as functional bleeding, functional amenorrhea, ovarian dwarfism and ovarian agenesis, exact knowledge of the anatomic and to some degree the physiologic condition of the ovaries can be obtained only by culdoscopy or exploratory laparotomy. The chief contraindication to culdoscopy is the presence of a fixed mass in the cul-de-sac. The authors regard culdoscopy as a valuable adjunct to gynecologic procedures.

Ulceration After Irradiation.—Influences which may contribute to ulceration following irradiation include, according to Hunt and Breit, systemic disorders such as hypoproteinemia, ascorbic acid (vitamin C) deficiency, allergy, anemia, arteriosclerosis, uncontrolled diabetes and syphilis; poor blood supply; infection of devitalized tissue; foreign body action of devitalized bone, cartilage or fascia; trauma—whether actinic, thermal, mechanical or chemical; inadequate regeneration of tissue due to nutritional disorders; residual or recurrent neoplasm. The occurrence of necrosis following irradiation is to be reduced by promotion of general health, provision of proper nutrition, preservation of blood supply, control of infection, protection against trauma, treatment of lesions while small, and elimination of cancer by the first course of therapy as far as possible. Experimental studies on acute radiodermatitis in rabbits showed onset to be delayed and severity reduced by avoidance of greasy applications, although the reaction was not aggravated by water or dry powder. Clinical observations suggest that the vesicular phase is benefited by sterile bland wet dressings and exposure to the air. Infection can be reduced by prompt closure of the skin and by bacteriostatic and antibiotic drugs. There are various ways to eliminate necrotizing tissues. The use of radon ointment is most effective in promoting regeneration of epithelium.

Postbulbar Ulcer of Duodenum.—According to Ball and his associates, ulcer craters in the duodenum are not commonly found distal to the bulb, but since there is hemorrhage in many of these cases, often of the massive type, it is important that a careful search be made for ulcer craters in the examination of the upper portion of the gastrointestinal tract. Ulcer of the duodenum located distal to the bulb displays a smooth, rounded indentation of the wall at the level of the crater with an eccentric narrowing in all cases examined. Enlarged, distorted mucosal folds, irritability of the bulb and hypermotility are associated observations. The ulcer crater is not always seen. The use of exaggerated oblique projections with the patient in the horizontal position or with the head lowered below the horizontal plane has been found to be helpful in disclosing the lesions of postbulbar ulcer. The incidence of postbulbar ulcer is difficult to evaluate. In cases of hemorrhage from the gastrointestinal tract, particularly in those cases associated with back pain and symptoms of peptic ulcer, the possibility of postbulbar ulcer should be seriously considered.

Rheumatism and Arthritis: Review of American and English Literature of Recent Years (Ninth Rheumatism Review). P.S. Hench and others. -p. 66.

Urine Volume and Total *Renal Sodium* Excretion.—Crutchfield and Wood say that the advisability of drastically reducing sodium intake in the edema of congestive heart failure is generally accepted. Recommendations concerning the optimal water intake during such sodium restriction, have ranged from the older view that fluids should be drastically restricted to the opposite extreme, that fluids should be forced even to 5 or 10 liters daily. The authors decided to investigate how fluid intake might be adjusted to assure in the average patient the greatest possible excretion of sodium per day. Approximately *one* hundred observations on water diuresis and sodium excretion have been made on 50 patients. Water diuresis was produced by oral administration of 1,000 cc. of tap water within fifteen minutes. It was found that in a patient who already has adequate urine volume, the exhibition of water diuresis does not increase total renal sodium excretion. To the contrary, in such a patient water diuresis usually decreases total renal sodium excretion. It is further suggested that the optimal urine volume for the patient with congestive heart failure, when related to water diuresis alone, falls between 2 and 3 liters daily. The efficiency of osmotic diuretics is impaired when combined with water diuresis. Xanthines and mercurophylline injection disproportionately increase urinary volume and total renal sodium excretion, favoring the latter. This suggests that the primary renal action of these substances may be depression of tubular reabsorption of sodium.

Incidence of Heart Disease.—Wartman and Hellerstein present a statistical study of the incidence of heart disease in 2,000 consecutive necropsies. The term heart disease is used in an anatomic sense and includes all organic lesions of the pericardium and heart, but it does not necessarily mean clinically evident disease. Nearly two thirds of the necropsies involved males. The age curve of the series was similar to that of deaths from all causes in the United States Registration Area for 1940. Forty-nine and two-tenths per cent of the patients had some cardiac lesion, although not all were sufficiently important to have contributed to death. Nineteen per cent died directly of heart failure. The cardiac lesions were divided into rheumatic heart disease, hypertensive heart disease, coronary artery disease and a miscellaneous group. Thirteen and six-tenths per cent of the total group had hypertensive heart disease. The age, sex and color distribution of 120 patients with rheumatic heart disease was as follows: the mitral valve was involved in every case, the aortic in 85, the tricuspid in 53 and the pulmonic in 15. Forty-nine patients with rheumatic carditis lived to be 45 years old or more. There were 16 cases of endocarditis lenta among the 120 cases of rheumatic heart disease. The coronary arteries were significantly diseased in 51 per cent of the 984 patients with heart lesions, or 25 per cent of the total series. Eighty-four per cent of patients with coronary thrombosis also had myocardial infarcts; 16 per cent died without myocardial infarcts, many of them suddenly. The factors concerned in sudden death following coronary obstruction were severe generalized coronary arteriosclerosis and multiple occlusions with occlusion of the predominant artery. The incidence of myocardial infarcts in the total necropsy series was 8.2 per cent. The left ventricle was the most frequent site of an infarct. The commonest complications of myocardial infarction were mural thrombi, fibrinous pericarditis, subsequent myocardial infarcts, aneurysm formation and cardiac rupture. Peripheral thromboembolism occurred in 45 per cent of cases of myocardial infarcts and were a main or contributory cause of death in 43 of 160 cases.

Chemical Meningitis Following Use of Tyrothricin.—Otenasek and Fairman have not found reports of ill effects in human beings from clinical use of tyrothricin. They report 2 patients seen at the Johns Hopkins Hospital exhibiting disastrous effects from this drug. Morbid effects in both patients were seen immediately after a frontal sinus had been irrigated with tyrothricin. There were severe headache, delirium, high fever and, in a very few hours, clinical and laboratory signs of meningitis. In both, the acute inflammatory process lasted less than a week, with apparent clinical cure but with delayed production of hydrocephalus as a consequence of adhesive arachnoiditis. The first patient had a stormy convalescence and left the hospital with no perception of light in the right eye and disturbance of visual acuity in the left. There also was some unsteadiness. The second patient died. Necropsy revealed hydrocephalus and chronic meningitis with thickening and round cell infiltration of the leptomeninges. The clinical experience with these 2 patients prompted experiments on animals. Of 35 dogs in whom 1 cc. of a 1:1,000 suspension of tyrothricin was injected into the cisterna magna, 18 died either immediately or within a few hours. Those with a survival period of a few hours showed massive swelling of the medulla oblongata at the site of injection, with almost complete obliteration of the foramen of Magendie in some cases. Animals surviving longer periods were killed at different intervals. The final picture revealed gross and microscopic thickening of the leptomeninges, with or without hydrocephalus. The authors stress that even extremely small amounts of tyrothricin in the cerebrospinal fluid may produce disastrous effects. When an opening of the dura mater is known to exist after a radical sinusotomy, irrigations with this agent should be scrupulously avoided. Routine and indiscriminate tyrothricin irrigation of infected cavities close to the subarachnoid space is to be avoided.

Nasal Hemorrhage.—Neivert and his associates studied 104 consecutive patients presenting themselves with nosebleed at the Presbyterian Hospital, New York. Ascorbic acid level and prothrombin time were normal in only 11 of these patients. The plasma ascorbic acid level was subnormal in 68 patients, of whom 35 also showed prothrombinopenia. There were 25 patients whose plasma ascorbic acid concentration was normal but whose prothrombin activity was subnormal. The nosebleed in 57 patients was traceable to one of the generally recognized local or systemic causes, but in 47 patients it was not. Vitamin therapy was instituted in 62 of the 93 patients found to be deficient in ascorbic acid and/or prothrombin. The clinical response could be determined in only 36 patients. Of these, 27 were improved. The extremely high incidence of ascorbic acid and prothrombin deficiency in cases of epistaxis and the gratifying clinical results attending the administration of ascorbic acid and/or a vitamin-K-like substance in some of these cases suggest that vitamins C and K have a definite place in the management of nasal hemorrhage.

Macrocytic Anemias.—Wills limits her discussion to the three principal types of macrocytic anemia: pernicious anemia, nutritional macrocytic anemia and tropical sprue. The interrelationship of these three entities is reviewed on the basis of reports in the literature and of unpublished work. The author considers these three clinical conditions as distinct entities possessing a common characteristic in the presence of a panhemopoietic dystrophy characterized by a megaloblastic erythropoiesis and corresponding changes in the myeloid cells and platelets. This panhemopoietic dystrophy possibly results from the breakdown of an intracellular enzyme system, but the deficiencies causing the breakdown differ; in pernicious anemia the liver principle is apparently at fault, in endemic nutritional macrocytic anemia another unidentified factor is missing and in sprue either or both may be at fault. Folic acid is active therapeutically in all three diseases, but in all it fails to restore completely normal blood levels. Pernicious anemia is probably due to a genetic defect which produces atrophy of the gastric mucosa. As a consequence of this interference with gastric function there is failure in the formation or absorption of the liver factor and possibly of another neurotropic factor, which failure results in the development of a macrocytic megaloblastic anemia and the characteristic changes in the nervous system. Indefinite replacement therapy is necessary, as the changes in the gastric mucosa are irreversible. Endemic nutritional macrocytic anemia is a food deficiency in a factor other than the liver principle, possibly a coenzyme present in or associated with good biologic protein and the vitamin B_2 complex. A hemolytic type of the disease occurs in areas of high malarial incidence. After successful treatment the disease does not relapse if the diet is satisfactory. Pregnant women are particularly liable to development of the disease. Tropical sprue is due to a functional disorder of the intestine, possibly primarily a failure in phosphorylation of fatty acids, glycerol and dextrose. Diarrhea and macrocytic anemia are present. The macrocytic anemia may be due to a failure in absorption of one or more essential hemopoietic factors or to a lack of Castle's intrinsic factor. A high protein diet and liver extract are most important in the treatment.

Therapy and Nervous System in Pernicious Anemia.—Bethell and Sturgis analyzed the clinical course, particularly the neurologic changes, in 70 patients with pernicious anemia, who were observed for periods of not less than ten years. Most of the patients, whether treated with oral preparations of stomach or liver, or with parenteral crude or refined liver extracts, showed significant improvement of their neurologic manifestations. The period of improvement was limited, essentially, to the first year of therapy. Thirty-six patients were maintained in complete hematologic remission. Fifteen of the patients did not adhere to an optimal therapeutic regimen, and their blood values were frequently abnormal, although definite relapses did not occur. In the former group there was no progression of neural lesions. In the latter such adverse changes as did occur were transient and reversible on resumption of adequate therapy. Nineteen patients had clinical and hematologic relapses after their initial response to intensive therapy. The end results in this group were not so favorable, but nevertheless serious progression of spinal cord involvement was seldom observed. The observations do not justify the conclusion that irregular or suboptimal therapy is without serious risk. The early results of treatment with synthetic folic acid, as observed in 15 patients, indicate that both the hematologic and the neurologic response to this form of therapy are much less predictable than is the case with stomach or liver preparations. It is suggested that disturbance of folic acid metabolism is not the sole cause of either the hematologic or the neurologic manifestations of pernicious anemia but that inability to utilize folic acid effectively may play a part in the development of both myeloid and neural abnormalities.

Spinal Cord Degeneration and Folic Acid.—Ross and his associates substituted synthetic folic acid (pteroylglutamic acid) for liver extract in treatment of 22 patients with pernicious anemia. The patients received this treatment for from eight to seventeen months. Satisfactory blood levels were maintained in all cases receiving daily oral doses of 1.25 to 15 mg. Severe hematologic relapse occurred within six months in a case treated with monthly injections of 30 mg. of the preparation. Synthetic folic acid in oral doses of 15 mg. daily induced satisfactory hematopoietic responses in 3 patients with pernicious anemia in severe relapse, but only slight hematopoietic response was obtained in a fourth patient with mild pernicious anemia but severe subacute combined degeneration of the spinal cord. Ten patients manifested a significant improvement in blood values for a few months after substitution of folic acid for liver extract. With one exception these subsided after six or more months to pre-folic acid levels comparable with those previously maintained with liver extract alone. These observations suggest that a combination of orally administered folic acid and parenterally injected liver extract may maintain a better hematologic status than either substance alone. A previously untreated patient with severe subacute combined degeneration of the spinal cord failed to show improvement in neural disease during twenty-eight days of folic acid therapy. Eleven patients manifested, or showed progression of, subacute combined degeneration of the spinal cord during folic acid treatment. Neurologic disease developed in most of these patients when the peripheral blood was normal. The institution of liver extract therapy in addition to folic acid in 5 patients in whom there developed subacute combined degeneration during folic acid maintenance therapy failed to prevent progression of the disease in 4 cases and only partially arrested the disease in the fifth, in which improvement occurred more rapidly when folic acid was discontinued. Subacute combined degeneration occurred with greater frequency in patients on large daily doses of folic acid than it did in patients with small or intermittent doses. This suggests the possibility that folic acid in large daily doses may actually precipitate or aggravate neurologic disease.

Refractory Megaloblastic Anemia.—Davidson applies the term refractory megaloblastic anemia to cases which failed to respond hematologically and clinically to the parenteral administration of an amount of liver extract which has been proved to produce an optimal response in cases of addisonian pernicious anemia. The preparation employed had been found to be potent in a dose of 2 cc. when administered parenterally in a large number of cases studied during the past ten years. Every patient with refractory megaloblastic anemia received at least twice this dose after admission to hospital. During the past six years 59 patients with megaloblastic anemia partially or completely refractory to potent liver extracts given parenterally have been investigated in Edinburgh. Thirty-four of these cases were associated with pregnancy, the puerperium or the sprue syndrome. No explanation of the cause of the megaloblastic anemia was discovered in the remaining 25 cases. Excellent therapeutic effects were obtained by proteolysed liver or folic acid in the 25 cases of idiopathic refractory megaloblastic anemia. With regard to the mechanisms involved in refractoriness to potent parenteral liver extracts the author suggests that chemical purification of liver extracts for parenteral use may remove some essential factor which is necessary for the restoration of normal blood formation in certain cases of megaloblastic anemia. It is possible that an unknown hematinic principle, in addition to the liberating factor in purified parenteral liver extract and folic acid, is required for the complete restoration of normoblastic blood formation.

Clinical Trial of New Synthetic Analgesic.—Bercel says that the new analgesic drug 6-dimethylamino-4,4-diphenyl-3-heptanone, known as 10820 or methadon, appears to have a morphine-like effect. Administrations of 2.5 mg. of Methadon raised the pain threshold to the same extent as did 10 mg. morphine sulfate. Bercel summarizes experiences with this new analgesic drug on 25 selected patients, all of whom had severe pain. The drug was given in various doses and in a variety of ways. More or less complete relief from pain was obtained by all but 3 patients. Ten patients complained of side effects. In 5 administration of the drug had to be discontinued because of undesirable reactions due to sensitivity. Skin tests are advisable. After daily administration of 5 to 60 mg. of the drug for periods varying from two to twelve weeks, the sudden withdrawal produced no physiologic withdrawal phenomena. The drug appeared to be a potent analgesic with an effect similar to morphine and demerol.

Hemochromatosis of Central Nervous System.—Neumann says that hemochromatosis, so named by von Recklinghausen, was first isolated by him as a clinical entity in 1889. Since that time more than 300 cases have been reported. Sheldon's study lists the chief criteria for the recognition of the disease as follows: brown pigmentation of the skin, widespread pigmentation of the viscera, muscles and connective tissues, cirrhosis of the liver and pancreas, and diabetes. Pigmentation of the brain is seldom mentioned in case reports, although it has been stated that the choroid plexus is almost uniformly involved. Neumann's case greatly resembled that reported by Lewey and Govons. There was relatively slight involvement of the viscera. The main neurologic signs accompanying the disorder are progressive ataxia and deafness. The cerebrospinal fluid is xanthochromic. Vomiting occurs frequently. The primary pathologic process is believed to have originated in the teloid roof of the fourth ventricle. In Neumann's case the superior surface of the cerebellum was intensely damaged. It is probable that this case and the few similar recorded cases constitute a clinicopathologic entity.

Histopathologic Aspects of Myotonia Atrophica.—Hassin and Kesert present the results of histopathologic studies on 3 patients with myopathies together with brief summaries of the clinical aspects. They stress that in myotonia atrophica there is a disproportion between the pathologic and clinical features. Myotonia atrophica is a definite morbid entity embodying some clinical features of myotonia congenita, progressive degenerative myopathies and extra muscular dystrophies (cataracts, baldness and other anomalies). The histologic changes are not specific, being similar to those seen in paramyoclonus multiplex and myotonia congenita (Thomsen's disease), but differ from those occurring in exquisitely inflammatory and degenerative diseases of the muscles. Myotonia atrophica is, like myotonia congenita and paramyoclonus multiplex, a metabolic disturbance which is probably responsible for the abnormal muscular activity that ultimately brings on pathologic changes.

Oral Penicillin for Respiratory Infections.— Hoffman and his co-workers treated 143 infants and children who had acute respiratory infections with a palatable solution of soluble tablets of crystalline potassium penicillin G without buffers. Dosage to be used every three hours for each age group was determined by an evaluation of assays of the plasma penicillin levels obtained after single doses in 209 control infants and children. Those between the ages of 1 and 12 years showed, one hour after the dose, average levels of 0.12 unit per cubic centimeter, and at three hours, 0.03 to 0.05 unit per cubic centimeter. Though dosage had been based on age, therapeutic plasma levels were obtained with doses of approximately 3,000 units per kilogram (or 1,400 units per pound). Infants under 1 year showed much higher levels, well sustained after three hours. High penicillin concentrations were probably produced by the relatively poor renal function of such young infants. In 94 (65.7 per cent) of the patients treated, fever subsided within forty-eight hours and clinical improvement occurred. Fair results were achieved in 26 (18.2 per cent) and poor results in 23 (16.1 per cent). Evaluation on the basis of positive bacterial cultures or high white blood cell counts only slightly increased the percentage of satisfactory results. Yet it was certain that a virus component was present in many cases. Plasma penicillin levels obtained were of the same order as those found in assays. Urticaria occurred in only 1 patient and there was only occasional vomiting. Thus oral administration of penicillin without buffers is to be considered a convenient and satisfactory method of treatment of respiratory infections in children, if adequate doses are used. Failure of response in forty-eight hours is the signal for increased dosage or change to parenteral penicillin.

Pertussis and Pneumonia Complicating Pertussis.— Brainerd treated 26 infants, average age 7.9 months, who had whooping cough complicated by pneumonia and 26 infants, average age 9.4 months, who had uncomplicated pertussis; he gave intramuscular injections of 2.5 cc. of pertussis hyperimmune gamma globulin on each of four successive days with a total dose of 10 cc. All patients with pneumonia were also treated with sulfadiazine. Response to treatment in the first group with pneumonia was considered excellent in 2, good in 9, moderate in 7 and equivocal in 5; 1 patient became worse, although he later recovered. Two patients died. In the second group results of treatment were excellent in 14, good in 4, moderate in 4 and equivocal in 4. No patient became worse or died. It was striking that no patient in this group contracted pneumonia or any other complication of pertussis. Hyperimmune gamma globulin appeared to shorten the course, lessen the severity and reduce the rate of complications. In combination with sulfadiazine it appeared to affect favorably the mortality rate of pertussis complicated by pneumonia. The maximum therapeutic effect of hyperimmune gamma globulin was obtained in patients treated during the first seven days of illness.

Bousfield's Reimmunization Against Diphtheria.— Masucci and his co-workers gave a varied dose of hard compressed tablets in which diphteria toxoid was incorporated to a group of 22 persons who had been immunized previously or had at some time come in contact with diphtheria, and to a second group of 15 Schick-positive persons who had no previous history of immunization or of exposure to the disease. In the first group some were given four tablets for seven days; others received three tablets for seven days and the remainder of the group received two tablets daily for seven days. The second group received four tablets daily for seven days. The tablets were placed under the tongue until they disintegrated completely. Bousfield's observation that diphtheria toxoid antigen can be absorbed effectively by the mucous membranes of the upper portion of the alimentary tract has been confirmed. In general persons who had received previous diphtheria antigen or who had been exposed to the disease showed a definite increase in antitoxin titer. In some the increase was pronounced. This method of immunization was ineffective in those persons who apparently never had a primary stimulus. The amount of antigen absorbed is sufficient to act as a booster dose but is not sufficient to provide an adequate stimulus for primary immunization. There were no local or general reactions. Bousfield's method therefore appears to be the most promising of all the nonparenteral methods of reimmunization thus far proposed. The large dose required (2,100 Lf units) may hinder its practical application.

Spray Irradiation in Polycythemia Vera.—According to Richardson and Robbins, treatment of polycythemia vera by spray irradiation was instituted at the Massachusetts General Hospital in 1932. Irradiation is given with the intention of covering a field extending from the neck to the knees. This requires a long target-skin distance, which varies from 215 to 250 cm., and can usually be accomplished with a 20 by 20 cm. cone. The area is centered at the level of the crest of the ilium, and anterior and posterior fields are treated on alternate days. The kilovoltage is 200; filtration is obtained with 0.5 mm. of copper and 1 mm. of aluminum, which gives a half layer value of 0.92 mm. of copper. The daily dose varies from 20 to 30 r measured in air, and the total dose in a series of treatment in usually 500 r. A white blood cell count is taken at the end of a week and at shorter intervals as the cells decrease. Treatment is stopped when the count falls below 5,000 to 6,000. Twelve of the 28 patients who have received spray irradiation for polycythemia vera are dead, but 4 died of causes other than the disease or its treatment. Of the 16 living patients, 13 are free of symptoms attributable to polycythemia; 1 has hypertension, 1 is anemic and 1 is still polycythemic and is considered a therapeutic failure. One patient has a refractory anemia, possibly or probably attributable to roentgen therapy. In no patient has there developed leukemia, a leukemic state or myeloid metaplasia. Phlebotomy is contraindicated in polycythemia vera except in the treatment of acute symptoms. Spray irradiation is considered the treatment of choice. The use of radioactive isotopes is discussed briefly.

Life Expectancy in Cancer of Prostate.—Beatty points out that it is seven years since investigation of the effect of endocrines on prostatic carcinoma was initiated. In this period management of this disease has been completely revolutionized. A life expectancy of one to two years has been lengthened to an average of three years, during most of which time the patient lives in comparative comfort. In this series, which covers a period of about five years, the average life expectancy of the patients who have been followed is 3 years for those still living and 3.4 years for those who have died. In the recent cases covering the past two years it is hoped that as the result of early recognition and prompt radical surgery survivals of five to ten years will be the rule rather than the exception.

Tantalum Wire Suspension in Facial Paralysis.—Schultz and Fowler say that Schuessler has substituted tantalum wire and thin sheet tantalum saddles in place of fascia lata as the suspensory material. Advantages claimed for this method induced the authors to utilize Schuessler's method in 2 cases. They noticed a tendency of the saddles to cut through the muscle bundles. One other disability produced by a complete facial paralysis is the inclination toward ballooning out of the paralyzed cheek in the enunciation of certain syllables. Futhermore, patients with facial paralysis who must wear dental plates have difficulty in maintaining their denture in position, since the action of the musculature of the unparalyzed cheek acts to force the denture toward the paralyzed side and loosen its contact with the alveolar ridge. The use of tantalum gauze in the repair of hernial defects suggested to the authors a means of overcoming both the cutting effect of the saddles and the flaccidity of paralyzed cheek muscles. They believe that if moderately large segments of tantalum gauze are implanted in the facial tissues the surrounding fibrous bands of tissue growing through the mesh will allow a more equitable distribution of the pull placed on them by a tantalum wire suspension than would a similar pull placed on the small amount of tissue enclosed by a tantalum saddle. Such an implanted gauze of tantalum wire will, if made sufficiently large and accurately placed, also lend support to the atrophic cheek and will aid in prevention of the ballooning out effect and the unwelcome mobility of the dentures. Case reports illustrate experiences both with Schuessler's method and with the modification developed by the authors. They admit that the suspension of paralyzed muscles cannot produce a result comparable to that produced by a repair of the facial nerve, which adequately reinnervates the paralyzed facial musculature.

Death From Sternal Puncture.—Bardhan presents histories of 2 patients in whom death occurred after sternal puncture. The guard on the puncture needle, which had been at 8 and 11 mm., respectively, in these 2 patients, had not slipped. In both cases the needle had punctured the posterior plate of the sternum only to a minute degree. However, the resulting laceration in the right ventricle was nearly an inch (2.5 cm.) long in each case. Subsequent studies on cadavers indicated that with the force of the jerky movements associated with sternal puncture, the sternum could be pressed down for nearly an inch and the soft tissues could be reduced in depth up to 4 mm. If the anterior mediastinum, which is, after all, only a potential space, is fully obliterated by the heart and there is an unsuspected increase in the range of the needle, there is nothing to prevent a traumatic rupture of the heart. There can be little doubt that the two deaths occurred in the foregoing manner. Apprehension caused holding of the breath; this in turn led to stretching of the heart and its approximation to the sternum. Jerky movements caused an unsuspected increase in the range of the needle. The needle then pierced the posterior plate of the sternum and caused a small prick in the heart. The heart having been put on maximal stretch, the prick rapidly became converted into a laceration by the rising intracardiac pressure. Hemopericardium followed, leading to mechanical arrest of the heart and to death.

Familial Idiopathic Methemoglobinemia.—Gibson and Harrison present observations on a family with idiopathic methemoglobinemia. The condition was discovered in 1 member of this family when he attended the outpatient department of a hospital for a minor injury. He was referred to the authors because of his cyanosis, and it was found that his blood contained a considerable amount of methemoglobin. Under treatment with ascorbic acid the methemoglobin content of the blood decreased, but the patient was not concerned about his cyanotic color and did not continue treatment. Several years later his identical twin brother attended hospital for an injury. He too was cyanotic, and examination revealed methemoglobin in the blood. When he said that several other members of his family were abnormal in color, 8 of the 9 siblings were examined and 5 proved to have methemoglobinemia. The father's blood was normal; the mother, who was distantly related to the father, had died at the age of 48 but had never been cyanosed. The blood methemoglobin of patients with methemoglobinemia can be kept at a low level with daily doses of ascorbic acid, and cyanosis is then hardly noticeable. The action of a single dose of methylene blue, even when taken by mouth, is much more rapid and complete. It seems preferable, however to recommend continuous treatment with ascorbic acid, a natural food constituent, rather than with methylene blue, which might have an unsuspected toxic action after prolonged dosage. It may be desirable to supplement the action of ascorbic acid with an occasional dose of 0.3 Gm. of methylene blue by mouth, particularly if the cyanosis shows signs of returning as the result of temporary failure to keep up the intake of ascorbic acid. The authors believe that the abnormal amount of methemoglobin is due not to any defect of the bone marrow but to a disturbance in the equilibrium between hemoglobin and methemoglobin, which in turn is probably due to a deficiency in enzymes. Erythrocytes of patients with idiopathic methemoglobinemia have been observed to be deficient in a coenzyme factor.

*Investigation of Benzene and Toluene Poisoning in Royal Australian Air Force Workshops. Mildred Hutchings, Sheila Drescher, F. B. McGovern and F. A. Coombs. -p. 681.

Benzene and Toluene Poisoning in Air Force Workshops.-Hutchings and her associates during 1944 undertook investigation of the effects of contact with aromatic naphthas on persons working in air force workshops. This large scale investigation was precipitated by the death of an airman from agranulocytosis and thrombocytopenia. The patient had been employed for two months, for one and a half hours per day, cleaning engine parts with kerosene and gasoline after the parts had been removed from a cleaning fluid of high benzene content; zinc chromate spraying was also carried on in the hangar, and the fumes were rather heavy during spraying. The postmortem examination revealed aplasia of the leukocyte and platelet elements; the red cells appeared to be affected to a lesser degree. From this and the patient's history of contact with benzene, it was concluded that the condition was due to *benzene poisoning* and that other personnel in contact with the agents should be investigated. An analysis of the fluids containing aromatic hydrocarbons included an engine cleaning fluid, various paints and thinners, and a rubber solution. The aromatic hydrocarbon content varied from 16 to 56 per cent. An estimation of the aromatic hydrocarbon content of the atmosphere showed variations between 0 and 1,400 parts per million The higher concentration existed only for short periods, but for the major portion of the time the concentrations were 10 to 35 parts per million. On the basis of their observations, the authors conclude that there is no need for routine blood examinations of men working in engine-cleaning and painting shops, provided that exposure is minimized. The authors outline the steps taken to provide good working conditions. New processes involving the use of different solvents are constantly introduced, and there is an urgent need for close cooperation between the technical services and the medical services, in order that adequate precautionary measures be taken.

•Study of 1,160 Cases of Rheumatic Valvular Endocarditis. C. Cortés and H. Villarreal. -p. 775.

Rheumatic Valvular Endocarditis.—Clinical records of 1,160 patients with rheumatic valvular endocarditis were studied in the National Cardiologic Institute of Mexico. Records of 147 necropsies in the same institution on bodies of patients who died with the disease were also studied. In the group of 1,160 patients there were 737 females and 423 males. Race was not a predisposing factor. A history of rheumatic fever was recorded in 656 patients and of chorea in 152 patients. Rheumatic heart disease without history of rheumatic fever was recorded in 430 patients. In the majority of cases the first attack of rheumatic fever was recorded between the ages of 11 and 20 years and the appearance of chorea between the ages of 6 and 10 years. Joint pain was the predominant symptom in most cases. The clinical diagnosis of valvular involvement was mitral in 1,122 cases, aortic in 209 and tricuspid in 20. Cardiac failure occurred in 512 patients. It appeared most frequently in patients between the ages of 20 and 40 years, especially in a variable period from three to ten years after the first attack. Disturbances of cardiac rhythm were encountered in 203 patients and of conduction in 69 patients. Fibrillation coexisted with mitral stenosis in 189 patients. Rheumatic heart disease coexisted with congenital disease in 6 cases, with syphilitic heart disease in 102 cases, with bacterial endocarditis in 18 cases and with hypertensive heart disease in 42 cases. Clinical diagnosis of the following complications was made: pericarditis in 16; pleuritis, 11; pulmonary infarct, 14; peripheral embolism, 41, and renal involvement, 26. The highest death rate occurred in patients between 11 and 20 years of age. Mitral stenosis and mitral disease were encountered in the majority of necropsies which revealed these complications and also in the majority of necropsies on the bodies of 127 patients over 44 years of age. Valvular syphilitic lesions were frequently encountered in the patients over 44 years of age.

•Penicillin in Gonorrhea in Children: Ambulatory Treatment by Injections. A. Wiederhold and A. Méndez. --p. 576.

Gonorrhea in Children.—Twenty-five children between the ages of 8 months and 12 years with gonorrhea were given penicillin therapy by mouth for six months followed by clinical and bacteriologic cure. The dose of the drug varied between 300,000 and 600,000 units. Penicillin by the mouth is rapidly eliminated in the urine, in sufficient concentration to kill gonococci. Treatment is simple, easy to administer and reliable. Patients have been observed for more than one year after recovery. None had a recurrence. Another group of 26 children between the ages of 2 and 12 years, also with gonorrhea, had intramuscular injections of penicillin in doses which varied between 100,000 and 250,000 units. Clinical and bacteriologic cure was obtained in 21. The purulent discharge and the presence of gonococci in the microscopic preparations of the secretion were maintained in the other 5. Higher doses of penicillin by the intramuscular route failed to cure the disease.

Simple and Successful Method of Formation of Artificial Vagina. F. Kovacs.—p. 290.
•Nutrition of Pregnant Woman in Relation to Malformations of Newborn. S. van Creveld.—p. 299.

Nutrition of Pregnant Women and Malformations in the Newborn.—Van Creveld reviews experimental investigations carried out in recent years which demonstrated the great importance of the diet during pregnancy in connection with the occurrence of deformities in the progeny. A relationship between an unsuitable diet in pregnant women and the occurrence of congenital deformities in the infants must be considered. He cites the case of a baby whose weight at birth was 2,600 Gm. and who had a partial cleft palate, together with micrognathia and partial syntarsalia of the second and third toe on both feet. The families of the father and mother were free from malformations, and parents as well as an older child were normal. During the pregnancy the maternal nutrition had been deficient in protein with hardly any fruit and little butter and fat . Observations on a group of 216 stillborn babies and infants who died within a few days after birth are suggestive. The majority of infants with evident congenital malformations and all premature babies were born of mothers whose nutrition during pregnancy had been extremely inadequate. In comparison, 91 per cent of the mothers whose babies were well at birth had had either a good or a fairly good diet during pregnancy. It has been demonstrated that if the mother contracts certain virus diseases, such as rubella, during the early months of gestation fetal deformities are likely to result. The author believes that the damaging effects of poor nutrition are exerted on the fetus chiefly during the latter part of gestation.

Rupture of Corpus Cavernosum (Improperly Designated as Rupture of Penis).. A. Puigvert and J. Macias. -p. 431.

Amino or Aniline Tumors of Bladder.—Billiard-Duchesne states that physicians in industrial practice for years have observed the frequent occurrence of hematuria among employees of plants where dyestuffs are produced. Tumors of the bladder, which are often found, are now recognized as of occupational origin and are designated as aniline tumors. "Aniline tumor of the bladder" is not quite correct, since aniline itself does not produce these tumors. Only certain compounds of the aromatic amines are regarded today as carcinogenic, namely, benzidine, alpha-naphthylamine, beta-naphthylamine, 4'-amino-2,3' azotoluène and 2-acetylaminofluorene. Data on the 17 cases under consideration reveal that ages of the patients vary between 39 and 74 years, the average being 53 years. Since this is the age at which tumors develop spontaneously, age may play a secondary role. In only 2 to 5 per cent of those with prolonged exposure do tumors develop; this suggests that some personal predisposing factor may occur. Single as well as multiple tumors occur; they may appear in any part of the bladder but especially in the lower half. Of 7 histologically examined tumors, 6 were cancerous and 1 was noncancerous. Differential diagnosis of an occupational and a spontaneous tumor must be based chiefly on a history of exposure and the occurence of such tumors in similarly exposed workers. Preventive measures suggested by the author include avoidance of more than five years of occupational exposure to substances like benzidine and alpha-naphthylamines and beta-naphthylamines; thorough preemployment examination and inquiry with regard to earlier employment in plants producing dyestuffs; the use of closed processes wherever possible; good ventilation; frequent washing of hands by the workers and a daily shower; periodic examination of blood and urine, and systematic cystoscopic examination of workers who have been exposed for five years.

Complications After Salpingography.—Ten Berge believes that gynecologists and radiologists give too little attention to the dangers of salpingography. Histories of 4 patients are presented in whom serious complications resulted from salpingography, with one death. The author recommends pertubation in place of salpingography. Danger of air embolism in pertubation is obviated if carbon dioxide is used instead of air. Although pertubation involves less danger than does salpingography, it too may cause a reaction in an infected focus, as illustrated by the author's fifth case. However, the reaction takes a milder course than does that elicited by salpingography.

•Refrigeration in Treatment of Arterial Obliterations of the Extremities. G. Bickel, and J. Fabre. -p. 1.
Problems of Fight Against Cancer. A. Zuppinger. -p. 6.
Some Actual Problems of Physiotherapy, Hydrology and Medical Climatology. K. M. Walthard. -p. 10.

Refrigeration Treatment.—Bickel and Fabre treated 4 patients, 3 women between the ages of 72 and 80 and 1 man aged 80, with gangrene of the lower extremities from obliteration of the arteries, by refrigeration. Amputation was postponed because of severe cardiopathy, advanced cachexia or refusal of surgery. The extremities involved were covered with a stocking of fine wool and then wrapped with ice bags up to 10 cm. above the ischemic zone. The ice was renewed every four hours. Refrigeration was discontinued every day for three hours. The extremity treated in this manner is cooled but not frozen. The nutritive requirements of the cells are reduced by a maximum, the formation of toxins responsible for the occurrence of shock is diminished, the exudative processes are limited, proliferation of pathogenic microbes is inhibited and a pronounced anesthetic effect is produced. Pain subsided within two hours after the initiation of the treatment. There was pronounced improvement in the local condition; in 1 case the ischemic zone was reduced by 6 cm.; in another case mummification of the previously moist and septic gangrene occurred and edema and suppuration subsided. The general condition improved rapidly, temperature was restored to normal and appetite increased. Amputation could be performed after two weeks of refrigeration treatment.

•Mortality From Diphtheria in Vaccinated and Nonvaccinated Persons. M. Blanco-Otero. -p. 3.
Technic of Intratibial Injection in Suckling Infants. R. Couder. -p. 4.

Mortality From Diphtheria.—According to Blanco Otero, vaccination with diphtheria antitoxin was initiated in Spain in 1940 and was practiced on a large scale. It became compulsory in 1943. With the first year of vaccination the mortality rate from diphtheria decreased by 50 per cent; the following year it decreased by 75 per cent. Within three years the mortality in the province of Soria dropped from 40 per hundred thousand inhabitants to 3; in the province of Segovia the mortality rate dropped from 29 before the prophylactic campaign to zero. A survey of the mortality in twenty-nine provinces revealed that of 702 persons who died from diphtheria, 659 had not received any vaccine, while 43 had been given a total or partial dose of vaccine. There was only 1 case of diphtheria and no fatality among 2,000 children aged less than 3 years who were vaccinated by the author in the district of Congreso (Madrid), and this during an epidemic and in children who lived under poor hygienic conditions. The mortality continued to decrease up to 1946, when it was one-fifteenth that in 1939, decreasing from 15.7 in 1939 to 0.9 in 1946.

•Clinical Trial with Di-Insulin. L. Brull and others. -p. 631.
Facts and Considerations with Regard to Diagnosis of Hypovitaminosis C. G. Barac. -p. 640.

Clinical Trial of Di-Insulin.—Brull and his co-workers treated 42 patients between the ages of 22 and 77 who had diabetes mellitus with di-insulin. 'Di-insulin,' a Danish preparation, is a mixture of equal amounts of ordinary insulin and of Hallas-Møller's "iso-insulin" (phenylureidoinsulin); the two insulins are miscible without affecting each other; i. e., the protracted action of the "iso-insulin" does not protract the action of the ordinary insulin. A wide W form of the twenty-four hour blood sugar curve is obtained, with two hypoglycemic notches, the hypoglycemic maximum being reached seven to eight hours after the injection. Results demonstrated that "di-insulin" may be used with advantage in all forms of diabetes mellitus by giving two injections of 30 units, 60 units daily, to patients with moderately severe or severe diabetes and by one injection of 30 units daily in mild diabetes. Doses of 50 units administered in one injection were well tolerated and did not cause hypoglycemia. As compared to ordinary insulin or to protamine zinc insulin, "di-insulin" has the following advantages: reduction of the total dose administered, reduction in number of injections, better control of the glycemia and particularly of the glycosuria. Patients with severe diabetes mellitus requiring massive doses of ordinary insulin or of insulin with protracted action are benefited by changing to "di-insulin."

Book Notices

Afecciones vasculares quirurgicas del encefalo. Por el Dr. Alfonso Asenjo F.R.S., F.A.C.S., director del Instituto central de neurocirugia, Chile, y el Dr. Enrique Uiberall, Consultor neurologo de la Clinica médica del Hospital San Borja y de la Sección B de medicina del Hospital del Salvador de Santiago, Chile. Paper. Pp. 308, with illustrations. Central de Publicaciones, Casilla 98, Santiago, Chile, 1945.

This monograph is based on a review of the literature and 32 cases studied by the authors, some of which were observed in Europe. The iconography, however, is new. The book is well illustrated but some of the roentgen photographs have been too much reduced so that the lesion is difficult to see. The authors use their own classification of these lesions, distinguishing the angiomatoses from the tumors. The congenital malformations are divided into (*a*) cavernomas, (*b*) telangiectases, (*c*) Sturge-Weber-Dimitri disease, (*d*) angiomas, venous and arterial and (*e*) arteriovenous aneurysms. The acquired angioses are traumatic arteriovenous fistulas and sacciform aneurysms. The tumors discussed are the hemangioblastomas of Lindau, angiogliomas and angioblastic meningiomas. The discussions of symptomatology, pathology, diagnosis and treatment follow classic lines, except that the authors believe pure arterial angiomas to be very rare. They use arteriography in the diagnosis, and the procedures outlined for treatment are reasonable and conservative. This monograph is an interesting and reliable guide for Spanish-speaking physicians.

Do You Have Body Control? Edited by Mrs. Helen J. Campbell Prepared for Punahou School Girls Physical Education Department, Honolulu, T. H. Exercises Designed by Miss Ruth Aust. Paper. Price, 50 cents. Chart; no pagination, with illustrations by Mrs. Bertha Lowrie, Miss Ruth Aust, 358 Young Hotel Building, Honolulu 9, T. H., 1945.

This pamphlet offers suggestions and describes exercise designed to bring about "body control," which is defined as the efficient use of the body in any movement. The brochure can be unfolded to form a large wall chart portraying a series of twelve exercises in black and white. Muscles coming into greatest use in each of the stunts are differentiated in the illustrations. Directions accompanying the exercises are clear and concise, and the illustrations are attractive. Some of the exercises are relatively strenuous and would require adaptation for persons long out of training or who have not practiced vigorous exercises regularly. Among the maxims found on the reverse side of the chart are suggestions relating to choice of exercises, learning to relax, improving posture and the value of physical recreation. In the school situation with adequate medical and educational supervision these charts may have real value. Indiscriminate use by the layman might on the other hand involve certain hazards, since directions include the prescription of local exercises for specific conditions. Precautions need to be set up by which all persons undertaking such an exercise routine will be ascertained through medical examination to be organically sound. Additional emphasis on the factors of suitable work, adequate nutrition, rest, relaxation, the use of preventive and therapeutic medical services and the avoidance of excesses might well be given.

The Twentieth Century Fund, Annual Report 1946. Paper. Pp. 47. The Twentieth Century Fund, 330 W. 42d St., New York 18, 1947.

The Twentieth Century Fund produces each year a relatively few publications. Recently they published the survey volume, "America's Needs and Resources," and the "Report" of the Fund's Foreign Economic Committee. The report indicates that the Fund spends half its current income on research—that is to say, on the execution of research projects through to publication—and 40 per cent on dissemination of information. Ten per cent of its income goes for overhead. The work in developing methods of public information may become the most significant contribution of the fund as a whole. Experiments have been made with motion picture and radio presentation of the results of the fund's research. Cooperation has been fostered with the chamber of commerce, the Y. M. C. A., the federal council of churches and the advertising council.

Pharmaco-Therapeutic Notebook. By H. W. Tomski. With a foreword by Hugh A. Dunlop, M.D., M.Sc., F.R.C.P. Cloth. Price, $4.50. Pp. 280. William Wood & Co., Mt. Royal & Guilford Aves., Baltimore 2, 1947.

This book was prepared to furnish pharmacists "essential notes on the various aspects of pharmaceutical practice." Designed for the British pharmacist, this book fails to carry out its purpose and is even less suitable for American pharmacists. The book presents short descriptive statements regarding a number of drugs arranged in groups according to the predominating pharmacologic action. However, the statements offer little or no pharmacologic information and deal chiefly with the clinical use of the agents. The selection of agents to be discussed is often unfortunate, and many of the recommendations are uncritical. For instance, among the recommended antimalarials are found Fowler's solution with iron and quinine (Baccelli's mixture) and sodium cacodylate. Mercury preparations are recommended for syphilis. A weird mixture of lithium and sodium hippurates is recommended for use in conjunction with various nitrites as a "hypotensive." The use of Latin titles cannot be criticized, since their use is customary in Great Britain, but many of the names applied to drugs common in this country will be confusing to the American pharmacist.

Differentialdiagnose der Lungenröntgenbilder: Besondere Berucksichtigung derjenigen Erkrankungen, die mit der Lungentuberkulose verwechselt werden können. Von Dr. Med. Rudolf Zeerleder. Mit einem Vorwort von Pd. Dr. Med. J. Morin und Dr. Med. H. Stöcklin. Second edition. Cloth. Price, 28 Swiss francs. Pp. 296, with 93 Illustrations. Hans Huber, Marktgasse 9, Bern 16, 1947.

This well prepared monograph considers most of the lesions that are seen by the roentgen examination. The author has arranged his material in a rather interesting form, considering lesions seen in the lung and mediastinum. The author discusses the diagnostic criteria clinically and roentgenologically and considers the conditions from which the various lesions should be differentiated. The book contains two hundred and ninety-six pages of text, reference and index, and there are ninety-three illustrations with drawings where it was necessary to emphasize shadows seen in the roentgenograms. The form of the book is not new, as a number of other authors have attacked the same problem in a similar way. Nevertheless this book is an addition to the roentgenologic literature and should bring help to those who can read German. The publishers have furnished a satisfactory paper, the print is readable and the illustrations are excellent. However, it should be stated that the illustrations are positive instead of negative.

Fracturas del extremo inferior del radio. Por el Dr. José A. H. Bulfaro. Tesis de doctorado, Universidad nacional de Buenos Aires, Facultad de ciencias médicas. Paper. Pp. 243, with 144 illustrations. Buenos Aires, 1946.

This is a Ph.D. thesis covering a circumscribed field, but the subject is handled thoroughly and scientifically. The monograph considers both para-articular and juxta-articular fractures of the radius as well as associated lesions. They are discussed from all angles, etiology, symptomatology, diagnosis and treatment, and this is prefaced by a short but entirely adequate review of the anatomy and kinesiology related to the subject, not omitting the radiologic aspect for which some valuable diagnostic hints are offered. The roentgenograms are sharp and clear, and their reading is considerably assisted by sketches placed beside them. The book is well written and clear and is amply documented by case reports. The classification is practical, the treatment simple and not unnecessarily complicated. The author's experience is well evidenced by many cases. Some new technical items are mentioned, such as the fixation clamp used for traction and mechanical devices for traction and spreading of the fingers with a new articulative factor for the thumb, which are simple and rather practical. The book is well worth reading and is a definite contribution to this subject.

The Selected Writings of Benjamin Rush. Edited by Dagobert D. Runes. Price $5. 433 Pages. The Philosophical Library, 15 East 40th Street, New York, 1947.

Mr. Runes deserves credit for assembling the "cream" of Rush's writings. More ought to be said and written about this truly great American, for there are many patriotic Americans who do not know even that he was a signer with Franklin of the Declaration of Independence!

Rush was born the day before Christmas (Dec. 24, 1745) on his father's farm just north of Philadelphia and was fortunate in having a highly educated and inspiring uncle, the Rev. Samuel Finley, who was headmaster in the academy and later took his nephew in as a student there. The boy must have been brilliant, for he was graduated from Princeton before the age of 15 and then spent six years studying under Dr. Redman as preceptor, as was the custom in those days, after which he went to Edinburgh and received his M.D. in 1768, aged 23. Then came a trip across the Channel to France, but he seems not to have cared much for the medical science he found there. He returned to Philadelphia, took an instructorship in chemistry in the College of Philadelphia, the first medical school in America, and eventually received an appointment as professor of the institutes and practices of medicine when the College became a university in 1791. Rush mingled with men in all stations of life and acquired much information, which he reduced to facts in the crucible of his fine mind. His interests and energies covered an amazing field and would be noteworthy even were he living today. Some of the titles to his papers have to do with slave keeping, to which he was opposed, a plan to make the United States a universal peacemaker, on helping the Africans, the defects of the confederation (not all the signers of the Declaration thought it sacrosanct), securities for liberty, capital punishment (to which he was opposed) and the essentials of good government. He had thought widely and deeply on the education which is best suited to a republican form of government and conceived a plan for a federal university. By nature Rush was sanely religious and recommended the Bible as a sort of textbook in the schools of his day. Natural and medical science were to him so closely allied that he lectured on animal life as a basis for the study of human physiology. He wrote on the different species of mania and phobia and on the "progress of medicine" (1801). Physicians have vices and virtues, which he carefully catalogs and then concludes that the virtues exceed the vices by far in the daily balance. There is a lecture delivered to medical students on the "duties of physicians," which, of course, were no different then than now. Among the titles listed in this book are an inquiry into the ways of the American Indian and his "medicine," concerning the climate of Pennsylvania, an account of bilious fever, the cause and cure of cholera infantum, common salt as a cure for hemoptysis, thoughts on "pulmonary consumption," arsenic in the cure of external cancers, on tetanus, medicine in the Revolutionary war, a new method for inoculating against smallpox, the noncontagiousness of yellow fever, the influence of alcohol and tobacco on human health and morals, the sugar maple tree in the United States and medical inquiries and observations on diseases of the mind.

Orthopedic Surgery for Nurses Including Nursing Care. By Philip Lewin, M.D., F.A.C.S., Professor of Bone and Joint Surgery, Northwestern University Medical School, Chicago. Fourth edition. Cloth. Price, $3.75. Pp. 563, with 255 illustrations. W. B. Saunders Co., West Washington Square, Philadelphia 5, 1947.

In this edition there have been certain important revisions. Information on poliomyelitis is brought up to date, and the section on preventive and postoperative measures is added. There is also an addition to some of the technical part such as strapping. The book should be judged from the point of view of furnishing information on orthopedics for nurses rather than as a book on strictly nursing technic. In this respect the book is admirably suited for its purpose. The information is thorough and detailed enough to be of real practical use without going too much into theoretic considerations. The description of operations and their purposes is clear, concise and adequate for the instruction of nurses. This book is a leader in its line and should be a valuable and indispensable addition to any library for nurses.

Precis de dermatologie. Par J. Darier, A. Civatte et A. Tzanck. Fifth edition by A. Civatte. Cloth. Price, 1700 francs. Pp. 1152, with 269 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6e, 1947.

A. Civatte has followed closely the plan of the previous editions by Darier and has changed the clinical descriptions in only slight degree, although he has discussed the more recent developments in dermatology with respect to etiology, pathogenesis and physiology. The present textbook retains the usual division of previous editions into two main categories, morphologic and nosologic, often requiring the reader to consult both sections. The clinical descriptions, however, remain outstanding in their clear and concise presentation of the essential data on the various dermatoses, and the book is unsurpassed as a reference in this respect. The author states that he has adhered to Darier's desire to limit the text to the scope of a manual, and consequently relatively few of the more recently described dermatoses are included in this new edition. The text can be recommended only for those who wish to find a maximum amount of information regarding the chief clinical characteristics of the well established dermatoses. An appendix thirty-eight pages long deals with treatment, covering general therapeutic considerations and offers a number of prescriptions to meet special indications.

The Rehabilitation of Speech: A Textbook of Diagnostic and Corrective Procedures Based upon a Critical Study of Speech Disorders. Book One: The Pathology of Speech and the Rationale of Its Rehabilitation. By Robert West, Professor of Speech Pathology, University of Wisconsin, Madison. Book Two: Remedial Principles. By Lou Kennedy, Associate Professor of Speech, Louisiana State University, and Anna Carr, Clinical Adviser in Speech, State Teachers College, Milwaukee. With a Chapter by Ollie L. Backus, Assistant Professor of Speech, University of Michigan, Ann Arbor. Book Three: Case Histories. Second edition. Cloth. Price, $5. Pp. 630, with 39 illustrations. Harper & Brothers, 49 E. 33rd St., New York 16, 1947.

The new edition of this well known textbook reports chiefly the personal experiences and opinions of the authors. The aspect of the medical specialist in the field of speech and voice pathology is given little consideration. As a result the medical reader will not accept some of the text or some of the illustrations, for instance, figure 21. That "whispering is harmless" in some disorders of the voice has been disproved by Dr. Hogewind. Lethargic encephalitis is not identical with sleeping sickness (p. 165). Some reliable methods to test the hearing of very young children have not been mentioned. Among the dyslalias the important clinical picture of multiple interdentality has been ignored. In the chapter on stuttering group treatment is recommended, although the group treatment of any other form of neurosis has not been accepted by most psychotherapists.

In general the book is a comprehensive study and offers to the reader useful information about the most important speech and voice disorders. Helpful therapeutic procedures are described, although there are a number of others which have been proved efficient and in some special cases superior. The fact that the book is a compound work accounts for the repetition of some of the material from chapter to chapter. The glossary containing some four hundred items is an excellent feature for the reader who needs easily to find terms briefly described.

The Yearbook of Psychoanalysis. Volume 2. Managing editor: Sandor Lorand, M.D. Fabrikoid. Price, $7.50. Pp. 280. International Universities Press, 227 W. 13th St., New York 11, 1946.

This is a collection of fourteen articles, mostly from well known psychoanalysts. There is no introduction to explain this special selection. It begins with a methodical article by Hartman and Kris defending the conservative point of view in this field which only recently has begun to emancipate itself from the domination of traditional views and practices. Fenichel in an article on psychosomatic phenomena essentially accepts Alexander's distinction between conversion symptoms which have a symbolic meaning and vegetative responses to emotions often called "organ neuroses." A lucid article of French on ego analysis contributes greatly to the value of this volume. Four articles by English authors (Jones, Flugel and Glover) are included. The volume contains the translated article of Freud: "Dostoievsky and Parricide." This is a penetrating analysis of "The Brothers Karamazov" which, like Hamlet and Oedipus Rex, is an intuitive elaboration of the Oedipus complex.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RHEUMATIC HEART: TROPICAL CLIMATE

To the Editor:—Because of the difference of opinion existing in the literature and among pediatricians and cardiologists regarding the advisability of moving a child 8 years of age with inactive minimal rheumatic mitral insufficiency to a tropical or semitropical climate, I would appreciate an authoritative opinion. If affirmative, please send information regarding the most suitable locations, preferably but not necessarily in the United States or its possessions.

Ralph C. Greene, M.D., Memphis, Tenn.

ANSWER.—As indicated in the question, scientific data are not available on which one may base an answer acceptable to all observers. There are many features to be considered, some of which may be briefly mentioned:

1. There are known areas of high and low incidence of rheumatic fever in the United States. This is better recognized now as a result of World War II experience with rheumatic fever. The data assembled by Hedley, the Metropolitan Life Insurance Company and the war experience are in close agreement. However, rheumatic fever may occur in any part of the United States, and all surveys conducted by experienced observers indicate that there may be more rheumatic fever and/or rheumatic heart disease in low incidence areas than was previously supposed.

2. Claims of observers that specific areas offer particular advantages over other locations have not yet been substantiated by satisfactory scientific data. Once rheumatic fever is active, there exists no proof that any climate alters the severity or duration of the disease or the outcome in the given instance.

3. Exposure to epidemic factors (group A, beta hemolytic streptococcus infections) influencing the natural history of rheumatic fever vary considerably in various parts of the United States. However, rapid transportation may alter this and make it necessary for rather complete isolation even in low streptococcus infection areas. This would mean a rural life and probably poor medical supervision. Further, the possible effect on immunity from long residence in such an area is unknown. There is a strong probability that such a residence must be permanent and continuous not only for the patient but for the patient's immediate personal contacts (family).

4. The usual environment (described by Paul as microclimate) of the person recovered from rheumatic fever or the possibility of greatly improving the environment without change in climate must be considered. Much can be done, in areas where rheumatic fever is common, to decrease exposure to hemolytic streptococcus infections.

5. Experienced observers in areas where rheumatic fever is common report that two thirds of those with rheumatic fever do well although remaining in the area where the disease begins.

6. Sulfonamide prophylaxis (and perhaps eventually penicillin prophylaxis) under careful medical supervision may greatly improve the foregoing results.

7. Psychologic and economic factors vary greatly and must be considered in each instance in which advice is to be given.

8. In the great majority of instances, transportation to another climate is impractical and cannot be considered as the solution to this many-sided problem.

INDELIBLE PENCILS

To the Editor:--A woman got a fragment (about 1 by 1 by 2 mm. in size) from an indelible pencil in her left cul-de-sac (eye). After twenty-four hours it was removed, leaving a small ulcer of the conjunctiva and a purple stain about 2 cm. in diameter. Aside from irrigations and anesthetic ointment, could any other treatment have been used? One week later vision was 25/20 and the stain had been completely absorbed.

Arthur M. Dougherty M.D., Dodge City, Kans.

ANSWER.--Indelible pencils are most commonly made of an aniline dye which is exceedingly corrosive, and wounds caused by them are, as a general rule, of a serious character. Unless the pencil lead with the stained tissue is promptly removed, the aniline dye sets up an aseptic necrosis of the tissues which results in chronic inflammation with encapsulation and cyst formation. When the orbit, the eye or any of its appendages are involved, immediate treatment must be instituted by removing the fragments of the staining substance and all surrounding necrotic tissue, as well. Postoperative irrigations of 5 to 10 per cent solution of tannin are considered useful, as they form an insoluble compound with the aniline dye. Sodium chloride, boric acid and bichloride of mercury are contraindicated. References to this subject may be found in the *American Journal of Ophthalmology* (25:72 and 123 [Jan.] 1942; 27:1048 [Sept.] 1944) and in the book edited by Conrad Berens, "The Eye and Its Diseases," Philadelphia, W. B. Saunders Company, 1936, p. 499.

BRONCHIECTASIS

To the Editor:. A patient has bronchiectasis diagnosed by iodized poppy seed oil 40 per cent ("lipiodol") and bronchoscopy in 1939. Cough and expectoration have been the only feature up to December 1947, when the patient began to run a low grade fever that at times reached 102 F. Since then fever and increased expectoration have persisted. Bronchoscopic examination performed in January 1948 revealed an active infection and large amount of secretion coming from the left lingular division and saccular appearance of mucosa extending down into the bronchi of the lower lobe. Secretion was obtained for culture and vaccine. Culture revealed no tubercle bacilli but did reveal Neisseria catarrhalis, pneumococci and Streptococcus viridans. The patient has had a five day course of penicillin and sulfadiazine, e.g., 15 grains (0.97 Gm.) every four hours sulfadiazine and 300,000 units penicillin in oil and wax once daily. This caused decrease in cough and expectoration and slight decrease in temperature. All gradually recurred after treatment was discontinued. Aerosol penicillin was then tried, 100,000 units four times a day for seven days, with the same results. The infection has been diagnosed as mantl pneumonia. What is mantl pneumonia? What course of treatment do you suggest? Will streptomycin be of value?

M. D., Pa.

ANSWER.—The term mantl pneumonia is unknown, nor does it appear in the medical dictionaries of Gould, Dorland or Stedman. Several possibilities to account for it may be mentioned: It may be an obscure eponym, it may be a misprint or it may be mantle pneumonia, which to some may mean peripneumonia. Peripneumonia implies inflammation of pulmonary tissue around areas of abscess, bronchiectasis or other lesions in the lung.

Before treatment is resumed it would be wise to determine, if possible, what is going on, whether the bronchiectatic process is spreading, whether abscess has formed or neoplasm is present. According to experience, a five day course of penicillin therapy may not be sufficient in certain cases of bronchiectasis. Treatment may have to be prolonged for weeks. Even then there is no guaranty of relief. Nothing can restore the destroyed or defective bronchial tissue. Antibiotic therapy merely controls infection temporarily. Any subsequent minor infection of the respiratory tract is apt to cause recurrence of symptoms. Penicillin need not be injected with peanut oil or beeswax; results just as satisfactory are being achieved by the injection of 100,000 units of penicillin in its usual diluent every twelve hours. According to the flora cultivated from the exudate, there is little reason to expect that streptomycin will be helpful. It may be tried empirically if thorough penicillin therapy fails.

If conditions are suitable, lobectomy might be considered. Treatment with vaccine of any kind is illogical.

HOME HEATING

To the Editor:—*Is it advisable to humidify homes in winter? If so, what is optimal humidity? In our locality, winter heating results in a sharp drop in the humidity of the home. I am particularly interested in its effect on the upper respiratory system. Frequently patients with respiratory problems are referred to dry hot climates like Arizona for relief. The Arizona climate is closely simulated by the hot dry air in our heated homes during the winter. Is it the contrasting effects of the hot dry atmosphere of the home and the relatively higher cold humidity out of doors that seems to render so many persons liable to frequent colds and flareup of latent sinus infections in the winter?*

H. C. Goldberg, M.D., Plainfield, N. J.

ANSWER.—Dry air in the home during winter in cold climates has two possible effects in relation to respiratory infection. It has been found that certain pathogenic agents of the respiratory tract, e.g., hemolytic streptococci and influenza virus survive much longer in dry environments than in moist ones. (Robertson, O. H., and others: A Study of the Nature and Control of Air-Borne Infection in Army Camps, *J.A.M.A.* 126:993, 1944; Loosli, C. G., Lemon, H. M.; Robertson, O. H., and Appel: Experimental Air-Borne Infection. I. Influence of Humidity on Survival of Virus in Air, *Proc. Soc. Exper. Biol. & Med.* 53:205, 1943) Disease-producing streptococci have been recovered from blankets four and one-half months after being contaminated by carriers of hemolytic streptococci, when such blankets were kept in a dry atmosphere. Thus in a household respiratory pathogens dispersed into the atmosphere accumulate on surfaces and in fabrics when the relative humidity is low. At medium relative humidities, on the other hand, the survival of both bacteria and viruses may be brief.

Concerning the effect of different degrees of relative humidity on the upper respiratory tract in relation to respiratory infection, surprisingly little information is available. A. W. Proetz (*J. Laryng. & Otol.* 49:557, 1934) has shown that drying of the nasal mucosa results in a break in the continuity of the mucus layer which not only makes possible direct contact of foreign material (e.g., infectious agents) with the cellular surface but interferes with the ciliary action which sweeps extraneous matter away from the nasal passages.

In making comparison of the hot dry air of a heated home in a northern winter climate with the hot dry atmosphere of Arizona one must take into account the important fact that one is an internal and the other an external as well as internal environmental condition. In the latter (Arizona) situation the doors and windows will be open, thus permitting free ventilation which reduces the environmental and aerial contamination with pathogens of the respiratory tract and in such climates the human reservoirs of these disease agents are much less frequent. It is possible that rapid changes of temperature and humidity such as one experiences in northern winter climates play a role in increasing susceptibility to infections of the respiratory tract, but except for the well known predisposing factor of actual chilling of the body surface under such conditions no certain information exists. However, it has been observed for a long time that sharp rises in the incidence of pneumonia tend to coincide with rapidly changing atmospheric states. (Robertson, O.H., and others: A study of the Nature and Control of Air-Borne Infection in Army Camps, *J.A.M.A.* 126:993, 1944; Loosli, C.G.; Lemon, H.M.; Robertson, O.H., and Appel, E.: Experimental Air-Borne Infection. I. Influence of Humidity on Survival of Virus in Air, *Proc. Soc. Exper. Biol. & Med.* 53:205, 1943)

BASAL METABOLIC RATE

To the Editor:—*Why is the basal metabolic rate decreased in subacute nephritis when there is no edema? What is the rationale of thyroid therapy in these cases? One of the popular methods of treatment is based on keeping the kidney at rest and keeping its metabolic activity to the minimum (e.g., "the rice diet"), and rest in bed is supposedly paramount. Would not thyroid therapy conflict with this view? The patient in question has a basal metabolic rate of minus 25 to minus 34 per cent, despite 4 to 5 grains (0.26 to 0.32 Gm.) of thyroid per day. Is there any explanation for resistance to thyroid in subacute nephritis?*

M.D., Montana.

ANSWER.—The basal metabolic rate is not necessarily decreased in subacute nephritis but may be lowered by rest in bed or inactivity and by undernutrition. A low basal metabolic rate may be normal for the particular individual apart from nephritis. If this is the case or if the hypometabolism is not associated with symptoms of hypothyroidism, there is no indication for thyroid therapy. Stimulation of general body metabolism by adequate doses of thyroid is certainly incompatible with the principle of rest for the kidney or any other organ. It is difficult to find a good reason for administering thyroid to patients with nephritis in the absence of true hypothyroidism, unless one wishes to treat hypercholesterolemia empirically.

The problem of resistance to thyroid medication is of general significance. It is well established that normal, or euthyroid, persons often show little response to 2 or 3 grains (0.13 or 0.19 Gm.) or even 5 or 6 grains (0.32 or 0.39 Gm.) of thyroid daily. On the other hand, the true hypothyroid or myxedematous patient is extremely sensitive to small doses, and each grain of thyroid above the daily requirement causes a proportionate rise in the basal metabolic rate and in serum precipitable iodine or thyroxin iodine, although the basal metabolic rate changes much more slowly than the serum iodine.

Many subjects with hypometabolism can tolerate several grains of thyroid daily without change in their basal metabolic rate. They also respond less to thyroxin intravenously. Their serum precipitable iodine may remain low for weeks and months during thyroid therapy. On cessation of treatment, the basal metabolic rate may fall rapidly, indicating suppression of activity of the thyroid gland by exogenous hormone. However, resistance to thyroid is relative only; on sufficient increase in dosage and duration of treatment typical effects will be obtained, including toxicity.

From the preceding facts it may be concluded that resistance to thyroid medication is probably a function of the ability of the normal thyroid to inactivate thyroid substance. At the same time, thyroid hormone production is depressed. In states of undernutrition, response of tissues to thyroid hormone may be reduced for as yet unknown reasons.

BOILING OF MILK

To the Editor:—I assume that my practice of giving a baby whole milk at the age of eight months is generally accepted. I advise the mothers to boil this milk, even though they use pasteurized milk, for three to five minutes, at least until the child is about 1½ years of age. The mothers come back and tell me that nobody else boils the milk, why should they?

Is it advisable to insist on boiling the milk for young children although the local supply of pasteurized milk is considered satisfactory from a bacteriologic standpoint?

M.D., Wisconsin.

ANSWER.—It is the general practice today to boil milk for infants under 9 months of age. After this time, it is not necessary to boil properly pasteurized milk, considered satisfactory from a bacteriologic point of view. During the prevalence of milk-borne epidemics in any community it is wiser to temporarily resume boiling the milk until the epidemic subsides.

TRANSIENT CEREBRAL PARALYSIS IN HYPERTENSION AND IN CEREBRAL EMBOLISM

With Special Reference to the Pathogenesis of Chronic Hypertensive Encephalopathy

G. W. PICKERING, M.B.
London, England

A variety of cerebral attacks occur in hypertension. In cerebral hemorrhage, consciousness is lost suddenly and is not usually regained before death ensues; when recovery does occur a permanent disability often remains. In thrombosis of a cerebral artery with massive infarction of the brain, consciousness is also suddenly lost, and when it is regained a hemiplegia, a hemianopia or other lesion usually remains. While the gross pathology of such cerebral attacks has been apparent since the early days of postmortem examination of the brain, there are others in which the disturbances in life are of much shorter duration and in which the appearance of the brain after death is less noticeably altered. These attacks, which are the subject of this paper, were at one time included in the symptom complex of uremia. They were first clearly distinguished from true uremia by Volhard,[1] who termed them pseudouremia, and are now generally known as hypertensive encephalopathy (Oppenheimer and Fishberg[2]). Volhard recognized that these cerebral attacks are not all of one kind and that there are clear differences both clinically and pathologically between the attacks occurring in acute and in chronic hypertension. It is with the attacks occurring in chronic hypertension that I am chiefly concerned here.

HYPERTENSIVE ENCEPHALOPATHY IN ACUTE HYPERTENSION

In hypertension of recent origin such as acute nephritis or pregnancy "toxemia," or in a chronic hypertension with recent exacerbation, attacks occur in which severe headache is followed by vomiting, drowsiness, bradycardia, convulsions and coma. These attacks may be preceded or followed by focal symptoms and signs, and clear up without residual nervous phenomena. Volhard pointed out the similarity of the clinical picture to that found in acutely raised intracranial pressure. For this reason and because of the frequent presence of papilledema, he suggested that the attacks were due to acute edema of the brain, an explanation previously suggested by Traube and subsequently adopted by Zwangemeister and others.[3] Gorke and Töppich, Blackfan and Hamilton, Volhard[4] and others have described cases in which death occurred after attacks of this kind in which evidence of cerebral edema was found post mortem. Acute edema of the brain may therefore be provisionally accepted as the pathologic basis of such attacks. Some doubt still exists as to the cause of this edema. Traube regarded it as a passive consequence of diminished blood protein and raised arterial pressure. He supposed that both of these factors usually operated and that a sudden fall in blood protein or a sudden rise in arterial pressure might further increase the passage of fluid out of the cerebral vessels into the brain substance and precipitate a cerebral attack. At that time neither of Traube's two operative factors could be measured. No clear evidence has since been produced to show that plasma protein plays any part. Hypertension has been found invariable, and Volhard, Oppenheimer and Fishberg and McAlpine[5] among others have shown that a further rise in arterial pressure often immediately precedes the attacks. Traube's explanation implies that the cerebral arterioles are relatively feebly constricted by the agent raising the arterial pressure in hypertension, so that the cerebral capillary pressure is raised. The feeble contractility of the cerebral arterioles to constrictor agents supports the hypothesis; as does the relationship that exists between pressure of cerebrospinal fluid and diastolic arterial pressure in hypertension.[6]

The current view as to the origin of cerebral edema is, however, quite different, and was put forward by Volhard, who supposed the cerebral edema due to ischemia of the brain. He considered that the cerebral arterioles were not less but more constricted than those elsewhere, so that the cerebral blood flow became so small that the capillaries were damaged by anoxia, and so allowed abnormal amounts of fluid and protein to pass out into the cerebral substance. The chief evidence produced for this widely accepted hypothesis is that a rise in arterial pressure precedes the attacks; this fact is of no great value as evidence, for it had been envisaged as a possibility by Traube when he was formulating a precisely opposite hypothesis. In 3 cases which I have observed myself and reported briefly elsewhere, the protein in the cerebrospinal fluid was not significantly different in and out of the attacks. B[illegible]

that the cerebral arterioles have never been found to constrict more strongly than arterioles elsewhere, to a constrictor agent; in fact, the reverse is true.

THE ENCEPHALOPATHY OF CHRONIC HYPERTENSION

Attacks similar to those just described may occur in chronic hypertension particularly if there has been a recent exacerbation, but the usual attack is quite different. To quote Volhard, "Next in frequency to headaches and vertigo there occur transitory amaurosis, hemianopia, aphasia, astereognosis, transitory monoplegia and hemiplegia and rarely epileptiform attacks." Clinically the most striking features of these attacks of sensory or motor paralysis are their brief duration, the tendency to complete resolution and the frequency with which consciousness is retained. Peabody[7] seems to have been the first to ascribe such transient attacks of paralysis to spasm of a cerebral artery, because in the case which he observed, of a man of 56 with some six transient attacks of right hemiparesis, neither a cerebral infarct nor complete occlusion of a cerebral artery was found post mortem, though the middle cerebral and other arteries were grossly atheromatous. According to this hypothesis, a cerebral artery suddenly contracts so fiercely that its lumen is almost or quite obliterated, the corresponding area of brain becomes ischemic and a corresponding localized sensory or motor paralysis ensues; after a shorter or longer interval the artery opens again, the previously ischemic brain recovers and the paralysis disappears. This hypothesis explains rather simply the clinical facts and caters to the popular demand for hypotheses involving the conception of vasospasm; hence it is almost universally accepted at the present day, certainly in the United States and Europe. The evidence for it is slight. Volhard[1a, b] argued that intermittent claudication, angina pectoris and dead fingers occurring in hypertensive disease gave evidence of similar transient and localized vascular spasm elsewhere; but it is now known that the first two are due not to spasmodic but to organic arterial occlusion and that dead fingers are not usually associated with hypertension and that they represent a peculiarity in the local response of digital arteries to cold. Osler[8] in supporting the hypothesis was influenced by 2 cases in which cerebral disturbances and dead fingers were associated; his first case in which digital gangrene, epileptiform attacks and bloody urine occurred together only in winter would now be recognized as an example of cold hemolysis; his second was an unusual and complicated case terminating in gangrene of an arm and death in coma, only to have been explained by a necropsy that was not obtained. The most important evidence for the hypothesis is obtained by examination of the brain after death. No local cerebral lesion was found by Peabody, and the small foci of cerebral degeneration found by Westphal[9] were held to be inadequate to account for symptoms in his cases. On the other hand, Davison and Brill[10] thought the small degenerative foci were the cause of symptoms in their 7 cases. The most extensive and most objective account of the cerebral lesions is probably that of Rosenberg,[11] who examined the brains carefully in 17 cases of malignant hypertension and 15 controls. In the cases of hypertension, massive cerebral hemorrhage was found in 4 cases and small and spotty hemorrhages with numerous infarcts of similar size in 5 cases. Single large infarcts occurred in 3 cases. He was impressed with the frequency of multiple miliary infarcts, which he found in 12 cases in basal ganglions, cortex, white matter, brain stem and cerebellum; they varied in size from 5 to 6 mm. across to minute softenings only seen with the aid of a microscope. These small lesions had been ascribed to vascular spasm by Westphal and Bär and by Spielmeyer[12] because no adjacent organic arterial lesion could be found. This was often Rosenberg's experience, but he found some infarcts adjoining thrombosed vessels. Rosenberg concluded that "in this study it was always possible to demonstrate regions of cerebral destruction where focal cerebral symptoms had been present during life, and in instances where the brain showed no destructive lesions the history revealed that episodic focal symptoms had not been present during life." He suggested from his anatomic studies that cerebral symptoms were of three kinds in malignant hypertension: (1) due to increased intracranial pressure (headache, vomiting, drowsiness), (2) due to multiple miliary cerebral lesions (a wide variety of transitory disturbances often without physical signs) and (3) due to large cerebral vascular accidents. Rosenberg's observations support the idea that attacks of transitory paralysis in hypertension are due to focal ischemia of the brain, but leave undecided the problem as to whether the ischemia is due to spasmodic or organic arterial obstruction, though in some cases the latter was clearly the cause.

Whether or not localized spasm of cerebral arteries occurs in the disease is not unimportant to the general conception of the mechanism of hypertension. It is extremely probable that raised arterial pressure is due to vasoconstriction, but the causal agent is not yet known. If the cerebral arteries in this disease do from time to time undergo vasoconstriction (*a*) so intense as to paralyze nervous activity in their distribution and (*b*) so localized that nutrition of the remainder of the brain is unimpaired, then it would follow from (*a*) that the agent has an intense constrictor action on the cerebral arteries and from (*b*) that the active substance can be released in significantly abnormal amounts at localized points within the cranial cavity. If the principle of the paucity of hypotheses is applied, the suggestion at once emerges that the agent causing hypertension is one produced within the cranial cavity. These implications of the hypothesis become all the more striking when it is added that in hypertension localized arterial constriction of similar degree is generally claimed in no other vascular territory except the eye. The implications need, however, be pressed no further, for it will be the function of this paper to show that the hypothesis is not only improbable but also unnecessary, and that it should therefore be discarded. That the hypothesis is improbable emerges from a consideration of the cerebral arteries and their behavior; that it is unnecessary is plain from the fact that precisely similar attacks mav occur when a cerebral artery is occluded by an embolus.

THE CEREBRAL ARTERIES AND THEIR BEHAVIOR

Anatomists have long stressed that among the arteries of the body, the cerebral arteries are peculiar in the relative thinness of their wall (fig. 1). Baker[13] has shown that the cerebral arterioles are also peculiar in that their media is chiefly composed of callagen, muscle being sparse and in places absent. The cerebral arteries do not look like arteries that would show intense variations in caliber in response to constrictor stimuli, nor in fact do they delay. Thus repeated investigation[14] failed to demonstrate cerebral vasoconstriction after stimulation of the cervical sympathetic fibers until Forbes and his colleagues[15] developed their technic of direct measurement of pial arteries through a closed window in the skull. Even so the constriction of the pial arteries is small and insignificant as compared with arteries of the skin (fig. 2). Again epinephrine directly applied to the cerebral arteries constricts them feebly, but when epinephrine is injected intravenously this action is more than overcome by the rise of arterial pressure, so that the pial artery actually increases in size. Bouckaert and Heymans[16] have shown that the cerebral vessels do not participate in the generalized vasoconstriction evoked by a fall of pressure in the carotid sinus. The clear picture of the cerebral arteries that emerges from both anatomic and physiologic investigations is thus of feebly contractile arteries reacting weakly or not at all to vasoconstrictor agents. Clearly the hypothesis of local spasm of a cerebral artery intense enough to produce paralysis of nervous function and ultimately necrosis of cerebral tissue is not one to be adopted if a reasonable alternative can be put forward. Such an alternative does arise from a comparison of attacks of transient paralysis occurring in hypertension with those occurring in embolism of the cerebral arteries.

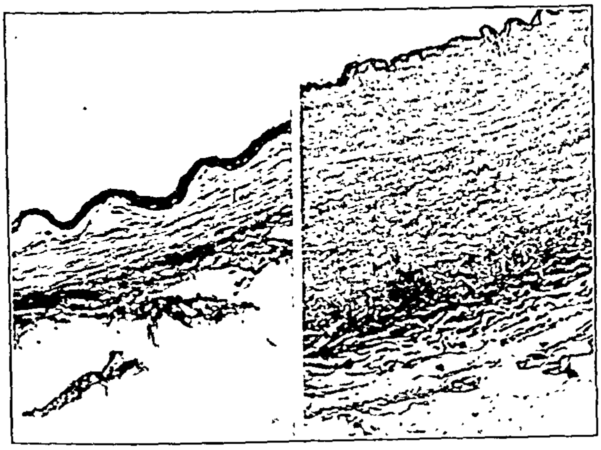

Fig. 1.—Transverse section (× approximately 84) through the wall of the radial artery and the middle cerebral artery of the same subject. This illustration was provided by Dr. Dohiach, British Postgraduate Medical School, London.

HYPERTENSIVE ENCEPHALOPATHY AND CEREBRAL EMBOLISM COMPARED

Hypertensive Encephalopathy.—Chronic hypertensive encephalopathy characterized by transient motor or sensory paralysis of cerebral origin is not very common. I have records of only 11 cases seen during the last 15 years, and these are summarized in table 1. Cases have, however, been described by Volhard, by Wagener, Keith and Kernohan, by McAlpine and others[17] and the clinical facts are well known. Typically when the patient is in good health and engaged in his usual daily occupations, paralysis of a limb or of half of the body, asphasia, sensory loss or blindness of an eye or of half of a field of vision abruptly supervenes. Consciousness is usually not lost, but the patient may be confused or excited. The condition may last a few minutes or a few hours and then gradually passes off, leaving the patient apprehensive or tired but without signs of any focal disturbance of the central nervous system. Such is the typical attack as it has been described. But while such attacks by their dramatic character focus the attention of the investigator, it is a mistake to think that there is an abrupt dividing line between these brief and evanescent paralyses and those which clear more slowly and which may leave residual symptoms and signs of a permanent lesion of the central nervous system. In fact, in my own experience, summarized in table 1, there is a continuous series from attacks in which paralysis is brief and totally reversible to those in which paralysis persists for months or years to leave some permanent residuum. By general consent the latter are regarded as due to cerebral arterial thrombosis; the contention here presented is that the former are also. The following report presents an example of a patient who experienced a paralysis of long and one of brief duration.

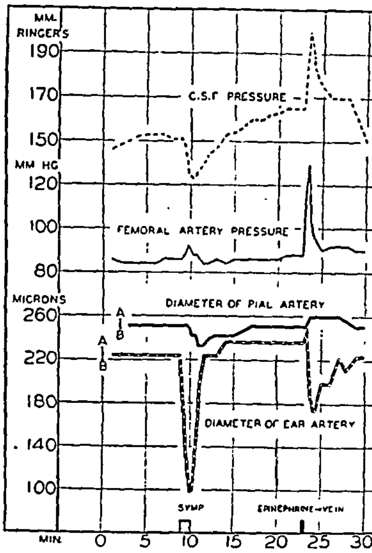

Fig. 2.—The lower two curves show the diameters of a pial artery and of an artery of the ear, measured in a monkey by direct observation. Stimulation of the cervical sympathetic constricted the pial artery by 7 per cent and the ear artery by 56 per cent. Intravenous administration of epinephrine dilated the pial artery by 4 per cent and constricted the ear artery by 26 per cent. (From Forbes, H. K.; Kinley, K. H., and Nason, G. I.: Arch. Neurol. and Psychiat. **30**: 957, 1933.)

Case 3.—J. C., an intelligent clerk of 41, was standing in a crowded underground train on Dec. 29, 1933, when his left arm and leg suddenly became weak. He did not lose consciousness or fall, but managed to stagger out of the train and walk 100 yards (91.4 meters) to a friend's office, whence he was taken home to bed. During his walk he tended to fall to the left. Since this attack he had noticed difficulty in articulation, in managing his dentures and in using his left arm and leg. These disabilities had slowly been recovering when he was first examined by me on Jan. 2, 1934. He showed the typical picture of severe essential hypertension (arterial pressure 220 systolic and 150 diastolic, normal urine and urea concentration to 2.5 per cent, and moderate retinal arteriosclerosis). He had slight but definite weakness of the left side of the face, the left arm and the left leg of the upper motor neuron type, deviation of the tongue to the right, exaggerated tendon jerks in the left upper and lower limbs, and a left extensor plantar response. Sensation and fields of vision were normal. By January 26, only weakness of the left side of the face remained. Ten months later, while at work he suddenly felt dazed and a severe headache developed lasting five minutes only. At the same time his left hand suddenly felt numb and weak, recovering in about five minutes. But for the next half-hour he kept hitting the wrong keys on the typewriter. For the rest of the day he was excited and walked about as if in a dream. He was discharged the next day for his behavior. Three years later, on Sept. 6, 1937, he woke with severe bilateral frontal headache. When he reached his office he found himself unable to speak intelligently, though he knew what he wanted to say and understood what was said to him. He was sent home, and said that his speech had recovered an hour from the onset. Seen by me later that afternoon he showed some slight residual difficulty in speaking; he was slow and hesitant but presented no other signs in the central nervous system. In December 1937, cardiac asthma, Cheyne-Stokes respiration and early albuminuric retinitis developed. He died of acute pulmonary edema, having maintained a severe hypertension throughout. Necropsy showed changes characteristic of malignant hypertension. The arteries of the circle of Willis showed moderately severe atheroma. A lesion of the cerebral substance characterized by pigmentation and irregular linear and punctate pits was found extending inferiorly from the junction of the middle and posterior thirds of the putamen into the internal capsule superiorly, and having a maximum area of 9 by 7 mm. No other focal cerebral lesion was found.

Table 1.—*Transient Motor or Sensory Paralysis of Cerebral Origin in Essential Hypertension*

Case	Patient	Age	Sex	Blood Pressure	Number of Attacks	Nature	Duration	Loss of Consciousness
1	J. T.	36	M	230/144	1	Hemiparesis, right; aphasia	20 min.	No
2	M. L.	47	F	260/140 260/140	1 1	Aphasia; paresis, arms Aphasia	1 hr. 1 hr.	No No
3	J. C.	41 42 45	M	220/150 220/150 220/150	1 1 1	Hemiparesis, left Paresis, hand, left Aphasia	2 mo. 5 min. 1 hr.	No No No
4	K. I.	37	F	250/140	1	Paresis, face and arm, right	2 days	No
5	E. C.	58	F	240/120	1	Hemiparesis, left; aphasia	days	No
6	L. L.	52	F	260/130	1	Hemianesthesia, right	days	No
7	H. G.	53	M	190/138	1	Hemiparesis, left	days	No
8	R. G.	65	F	230	1	Aphasia; paresis, face, right	7 days	No
9	L. C.	63	F	220/115	1	Paresis, arm, left	7 wk.	No
10	S. H.	41	M	230/160	1	Aphasia; hemiparesis, right Hemianesthesia, right	2 wk. Persists	No
11	E. S.	56	F	254/140	1	Paresis, arm and face, right Leg, right, 7 days later	1 mo. Persists	No

The only other case which need be cited is the following, in which coronary thrombosis, proved at necropsy, was followed four years later by a spectacular attack of transient paralysis lasting twenty minutes and leaving no clinical sequelae; but a small cyst was found in the putamen at necropsy four months later.

Case 1.—J. T., then a 32 year old sergeant in the 8th Army, had a sudden attack of severe pain over the lower part of the sternum while at a Christmas party in North Africa in 1942. He had to lie down, and the pain passed off after twenty minutes. He felt easily tired subsequently. In August 1943, while he was on a march in Palestine, pain developed over the sternum which spread across his chest and down the left arm. The pain gradually reached a maximum at which it remained during the last hour of the march; he was short of breath and sweated profusely. At the end of the march he lay down, and the pain passed off in about fifteen minutes. Subsequently he often experienced sternal pain on exercise, relieved by rest, and he was discharged from the army in December 1943. He eventually obtained a clerical post, and apart from angina and occipital headache on waking remained in fair health until Dec. 20, 1946, when at 10 a. m. while sitting at his office desk he noticed that his lower lip on the right side was numb. He bit his lip to confirm this. Then the fingers of his right hand became numb, and he found that he could no longer write. He could neither form the letters nor put the words on paper in their correct order, though he knew what he wanted to say. He thought that there was no weakness of the right hand, but it was clumsy and movements were difficult. He went into the next office and found that he could not speak; he knew what he wanted to say but the words were jumbled and his colleagues accused him of being drunk. All these disturbances cleared up completely in about twenty minutes, and he was able to continue his work for the rest of the day. Shortly afterward his eyesight began to fail, and he came to the hospital. Examined on Feb. 3, 1947 (now aged 36) he showed gross hypertension (230 systolic and 144 diastolic) in the malignant phase (bilateral albuminuric retinitis), gross enlargement of the heart with gallop rhythm, normal urine and renal function and no abnormal signs in the nervous system. The patient died of acute pulmonary edema on April 7, 1947 after adrenalectomy. Post mortem, the heart weighed 400 Gm., the left ventricle being 2 cm. thick; an old infarct was found on the endocardial surface of the anterior wall of the left ventricle near the base and involving the contiguous part of the interventricular septum; the corresponding branch of the left coronary artery was thrombosed, the remaining coronary arteries showing only slight atheroma. The brain showed only slight atheroma of the basal vessels and of the left and right middle cerebral arteries traced as far as the insula. A yellowish cyst, 5 mm. by 5 mm. by 3 mm., was found in the left putamen in the same vertical plane as the mammillary bodies.

Of the 11 patients whose cases are summarized in table 1, L. L., R. G. and S. H. (cases 6, 8 and 10) died out of hospital from apoplexy three years, one year and three months respectively after the attacks named in the table. The brain was examined post mortem in only cases 1, 2 and 3. All 3 patients died of malignant hypertension with severe arteriolar lesions, particularly of the kidney. Cases 1 and 3, already described, each showed a cyst of the putamen clearly ischemic in origin, though no evidence as to the nature of the old arterial obstruction was obtained. In case 1 an old myocardial infarct due to arterial thrombosis was also found. Case 2 presented a large number of small yellowish brown cysts about 2 mm. in diameter scattered through the basal ganglions of both hemispheres and two similar areas in the left pons. These findings in general agree with the more numerous and detailed observations of Rosenberg in showing that focal ischemia has occurred in cases presenting transient paralytic attacks.

The cases here reported and those of others show clearly that in hypertension there is no sharp dividing line between paralyses of cerebral origin that are transient and those that clear more slowly leaving a residue, and that both kinds of attacks are associated with focal lesions of ischemic origin in the brain. It may reasonably be inferred further that the nature and duration of the attack will vary with the size and position of the ischemic lesions. A persistent disability is more likely to arise from large infarcts than from small, and from lesions leaving a final area of necrosis in tracts such as the internal capsule than from lesions involving the silent areas of the brain. Histologic evidence leaves the cause of these ischemic lesions uncertain; serial sections sometimes reveal thrombosis of an artery, sometimes not, and this is true whether the infarct is large or small. Two chief possibilities exist; the ischemia may be due to organic arterial obstruction, for example, by a thrombosis; or it may be due to spasm. The evidence provided by the occurrence of similar attacks in mitral stenosis and auricular fibrillation may now be considered.

Cerebral Embolism.—For many years I have been struck by the close similarity between the type of hypertensive cerebral attack just described and attacks occurring in patients with mitral stenosis and auricular fibrillation but without hypertension. The cases that have come under my notice are summarized in table 2 and are briefly as follows:

Case 12.—W. E., a laborer aged 56 suffering from auricular fibrillation without valvular disease and with normal blood pressure (150 systolic and 80 diastolic), was admitted in 1939 for attacks lasting one-half hour in which he become giddy and breathless (thought to be due to paroxysmal ventricular tachycardia). In June 1939, when straightening up after taking a plant out of a pot he suddenly noticed blindness in the left eye. He was able to stumble into the house and upstairs to bed, where after half an hour his sight recovered. He was giddy at the time but noticed no disturbance in arm or leg. Examined four months later, the retinal arteries were of equal size in the two eyes and no signs were observed in the central nervous system.

Case 13.—A. N., a schoolmaster aged 52, had noticed irregularity of the heart since 1941. In 1942 while returning from watching a boxing match he noticed that he was walking badly and went into a public house to get a whisky. He could not get the money out of his pocket because his left hand was useless, and he could not talk. He was recognized, and some men in the public house carried him home in a hand chair; he was perfectly conscious and remembers clearly seeing the people pass by. When he reached home he was laid on a couch unable to move his left hand or left leg and unable to talk. He remained so for half an hour, and then quite abruptly and within a minute or two he found he could talk normally and move his limbs. He never had a similar attack before or since. Examination two years later showed mitral stenosis and auricular fibrillation but no abnormal signs in the central nervous system and a normal blood pressure.

Case 14.—J. F., with mitral stenosis was known to have had auricular fibrillation since October 1942. In the evening of Oct. 30, 1943, just after a routine visit to his physician he felt dizzy on reaching home and lay down on a couch. He did not lose consciousness, but his wife noticed that he was confused and that the left side of his face and his left arm and leg were paralyzed. His nephew, a doctor who had just been my house physician, and his own physician were called and arrived thirty minutes later to find left hemiplegia and confusion of thought. The paralysis cleared gradually during the next thirty minutes, and after receiving "omnopon" (a proprietary mixture of opium alkaloids, papaveretum BPC) he slept with periodic breathing. In the morning he was still confused but was said to present no trace of paralysis. I examined him later in the day and found him still rather confused and with only the slightest weakness of the left upper limb and of movements of the left ankle. The tendon reflexes were brisk and equal and the plantar responses normal. By November 4 he had lost even these trivial signs. In May 1944, when I last heard from him, he had had no further attacks.

Case 15.—W. M., an insurance clerk aged 28, had suffered from rheumatic heart disease with auricular fibrillation for many years but still traveled 20 miles (32.2 kilometers) by train to London each day to his work. In 1935 while at his office desk his right hand abruptly became weak and clumsy and he found himself unable to hit the keys on his typewriter. At the same time he found himself unable to see out of his left eye. He was quite sure of this, for he covered first his left eye and then his right eye with his left hand. He felt confused and was unable to speak clearly, he believed. The attack lasted about an hour and then passed off completely, but my notes do not say whether the end was sudden or gradual. I saw him three months later and found signs of mitral stenosis and auricular fibrillation with aneurysmal dilatation of the left auricle. There were no signs in the central nervous system, but unfortunately the fundi were not examined. I heard from Dr. D. Bedford, his physician, that he died of cardiac failure a few years later without further attacks. There was no necropsy.

Case 16.—C. S., a girl of 15 years suffering from mitral stenosis and auricular fibrillation, was treated with quinidine and her rhythm restored to normal in 1927. In 1928 she was

Table 2.—*Cerebral Embolism in Mitral Stenosis and Auricular Fibrillation*

Case	Patient	Age	Sex	Heart	No. of Attacks	Nature	Duration	Loss of Consciousness
12	W. E.	56	M	Auricular fibrillation	1	Loss of vision, left eye	30 min.	No
13	A. N.	52	M	Mitral stenosis, auricular fibrillation	1	Hemiparesis, left; confusion	1 hr.	No
14	J. F.	50	M	Mitral stenosis, auricular fibrillation	1	Hemiplegia, left; confusion	1 hr.	No
15	W. M.	28	M	Mitral stenosis, auricular fibrillation	1	Paresis, hand, right; blind, left eye; aphasia	1 hr.	No
16	C. S.	15	F	Mitral stenosis, auricular fibrillation	1	Hemiplegia, right; aphasia	2 days	No
17	R. H.	30	F	Mitral stenosis	1	Hemiplegia, left	1 wk.	No
					1	Hemiplegia, right; aphasia	Persists	Yes
18	L. O.	41	F	Mitral stenosis, auricular fibrillation	6	Hemiparesis, left	1 hr.	No
					2	Hemiparesis, left	2 days	No
					1	Hemiparesis, left	2 mo.	No
19	B. T.	49	F	Mitral stenosis, auricular fibrillation	1	Hemiplegia, left	Months	No
20	G. W.	46	M	Mitral stenosis, auricular fibrillation	1	Hemiplegia, left	Residue at 2 mo.	No
21	D. O.	26	F	Mitral stenosis, auricular fibrillation	1	Hemiplegia, left	Residue at 4 mo.	No
22	J. J.	76	M	Auricular fibrillation	1	Hemiplegia, left	Died, 24 hr.	Yes

readmitted to University College Hospital under Sir Thomas Lewis, with congestive failure and treated with digitalis. At 1:45 p. m. on Nov. 12, 1928, she was noticed to be throwing herself about, the right corner of her mouth was down and she was trying to make herself understood but could only repeat words such as "jing." She understood what was said to her and could answer yes or no. She exhibited facial weakness on the right side and a flaccid paralysis complete in the right arm and nearly complete in the right leg. The tendon reflexes were not obtained in either leg; the plantar responses were flexor on the left, extensor on the right. There was no loss of consciousness. At 5:30 p. m. she could talk well, and the weakness had passed off to a considerable extent. On November 13 she appeared a little drowsy but otherwise normal entally. Slight weakness of the right side of the face and upper and lower limbs persisted, and the right plantar response was still extensor. On November 14 no weakness was found, but the plantar response was not tested. On November 15 the right plantar response was recorded as flexor. She was discharged on Feb. 6, 1929, still fibrillating but with no signs of failure or hemiplegia. She died in hospital of terminal bronchopneumonia on Jan. 6, 1932. Her brain was examined post mortem by Dr. R. T. Grant, who provided me with all her case notes. The brain, sliced horizontally, was normal except for a yellowish cyst, 14 mm. long, 4 mm. wide and 7 mm. deep, in the putamen of the left lenticular nucleus. To find the vascular lesion responsible for this cyst, the middle cerebral artery and its chief branches were opened up under the dissecting microscope; the arteries seemed normal. A block of tissue extending from the lesion to the base of the brain was cut in transverse serial section 10 microns thick. No lesion was found in any artery of the block.

Case 17.—A married woman of 30 was walking across the hall to her office one day in the autumn of 1939 when she felt queer and had to sit down. Onlookers thought she looked ill and sent for a physician, who sent her to Charing Cross Hospital; there she was kept for the afternoon and then sent home to bed. Her memory of the attack is that she felt hot and giddy but never lost consciousness; her face became drawn to the right and she talked queerly; her left leg dragged and her left arm was useless when she went to bed. On the first day she had difficulty in controlling her bladder. Her limbs recovered gradually, but she has since noticed that her left arm twitches and becomes useless for a few minutes when she is tired. She was admitted to the hospital in November 1941 with congestive cardiac failure, mitral stenosis with normal rhythm and normal arterial pressure (140 systolic and 100 diastolic). No abnormal signs were found in the central nervous system. She was treated with digitalis and discharged home. On July 21, 1942, her husband had found her normal on leaving home in the morning but unconscious on his return at night. She was admitted to the hospital in coma with stertorous respiration. The right side of her face was flabby and her right arm motionless, and both plantar responses were extensor; she was incontinent. She had congestive cardiac failure, but her rhythm was still normal. She slowly emerged from her coma, regaining control of the sphincter on July 25, and showing some recognition of her husband. She was discharged on Oct. 24, 1942, with a severe residual spastic paralysis of right arm and leg and weakness of the right face. She recognized what was said to her and could reply by a nod of the head, but her articulation was so imperfect that few could understand her.

Case 18.—L. C., a married woman of 41, was seen in 1941 when she had had ten normal pregnancies, the last six years previously. In 1936 she had an attack when she suddenly felt a buzzing in her head, the room seemed to go round and she fell to the floor without losing consciousness. When she tried to get up she found that she could not, for weakness of the left arm and leg. The left side of her face felt queer and she had difficulty in pronouncing her words properly. She recovered completely in an hour. During the next six years she had four further attacks similar to the first in which weakness of the left side lasted about an hour and three in which it lasted two or three days, but she had not lost consciousness in any. On Feb. 26, 1941, She had just come in from shopping when something "seemed to go click" in her head and she fell to the ground. Again there was no loss of consciousness and her left side was paralyzed. She could see normally but her mouth felt pulled over. The left leg recovered its power to some extent in the next few days, but when she was brought to the hospital six days after the attack she was found to have a spastic paralysis of the left arm, paresis of the left leg and weakness of the left side of the face of upper motor neuron type, and mitral stenosis with auricular fibrillation and a heart rate of 160 per minute. The plantar response was extensor on the left, flexor on the right. The arterial pressure was 144 systolic and 95 diastolic. Lumbar puncture on April 8 showed a clear colorless fluid not under pressure. By May 6 the left leg had recovered completely, but there was still slight weakness of the left side of the face and the left upper limb. In 1944 she had her eleventh confinement, before which she was admitted to hospital with congestive cardiac failure from which she made a good recovery. She was last seen in March 1946, when she had no signs of cardiac failure but was still fibrillating. She had had no further attacks and the signs in the central nervous system had disappeared.

Cases 19 and 20 will not be described, since these patients gave stories rather similar to that in case 21, without, however, having been so fully observed by me.

Case 21.—D. C., a spinster of 26 on Dec. 30, 1945, was kneeling down putting a dish in the oven when she felt queer and fell over backward, bumping her head. She called her cousin to help her because she could not get up. Her cousin stood her up, but she fell over into the fireplace. She could talk normally, but she had no use of her left arm, and her legs, particularly the left, were weak. She was quite clear in the head; she could understand what was said to her, could see well and had no vertigo. Thirty minutes later she was seen by Dr. Mandler, who found a left hemiplegia and sent her to the hospital. She was seen by my registrar, Dr. James, seven hours after the onset, when she showed incomplete paralysis of the left lower part of the face and complete flaccid paralysis of the left arm and leg, with diminished tendon jerks and a left extensor response. The eyes showed conjugate deviation to the right. Lumbar puncture the following day showed a clear fluid with no cells and 30 mg. of protein per hundred cubic centimeters at a pressure of 240 mm. There was slow recovery of power, but on April 9, 1946, the left arm still showed some weakness of the hand and fingers, while the left leg showed definite weakness, especially of the dorsiflexors of the ankle. The plantar responses were now both flexor.

Case 22.—J. J., a man of 76, was admitted to the hospital on April 30, 1944, with a history suggestive of a coronary thrombosis a few hours previously; he showed signs of acute pulmonary edema and of auricular fibrillation. He made a good recovery and was progressing favorably until, on May 7, 1944, while he was having breakfast, the right side of his face was seen to go weak and he became unconscious. A right hemiplegia with flaccid paralysis of the limbs, absent tendon jerks on the right and a right extensor response was found. He died the following day without recovering consciousness. Postmortem examination showed a recent thrombosis in the descending branch of the left coronary artery and a corresponding recent infarct of the heart. An embolus was found in the right middle cerebral artery which had produced an area of softening in the hemisphere about 3 inches (7.6 cm.) in diameter.

In mitral stenosis and auricular fibrillation the sudden development of ischemia affecting part or all of an organ is usually due to embolism of an artery, as operation[18] or postmortem examination shows, the embolus being expelled from the left auricle and lodging at the bifurcation of an artery or at the origin of a large branch where the caliber of the artery is abruptly reduced. It may therefore be assumed that the cerebral attacks summarized in table 2 were due to cerebral embolism. This was proved only for J. J. (case 22), who died twenty-four hours after the attack. The only other patient coming to necropsy, C. S. (case 16) showed no evidence of embolic arterial obstruction three years after the attack despite careful examination. Nevertheless no other cause can reasonably be suggested in this case, for she was only 15 years old, the main cerebral arteries were normal and she had no hypertension. The conclusion from this case is rather that present methods of examining the cerebral arteries do not usually reveal the cause of vascular obstruction unless this is very recent. The diagnosis of cerebral embolism is supported by the frequency with which the right side of the brain or eye (10 cases) was affected as compared with the left (4 cases), since the right carotid presents the more direct path. In concluding that embolism was the cause of the cerebral attacks of table 2 a reservation must be made of case 18, which was peculiar in that a total of eight attacks of left hemiparesis occurred, the last leaving a residue for two months. It is inconceivable that eight separate emboli were delivered to precisely the same small vascular territory and to that only. Other known causes such as epilepsy and tumor were excluded by the history and course, but in the absence of postmortem examination any explanation is pure speculation.

[18] (a) Key, E.: Embolectomy for Embolic Disturbances, Acta chir. Scandinav. 54:339, 1922. (b) Jefferson, G.: Arterial Embolectomy, Brit. M. J. 2:1090, 1934.

It is not surprising that manifestations of focal cerebral ischemia should begin suddenly when an embolus occludes a cerebral artery. What is surprising is that the manifestations should be so brief and clear so completely in so many cases. It is, of course, well recognized that the degree of nervous impairment resulting from an organic lesion of a cerebral artery is greatest soon after the lesion occurs and then gradually recedes and that this is due at least in part to a gradual decline in the volume of ischemic cerebral tissue. Three reasons have been given to account for this phenomenon; namely, that brain tissue around the ischemic area is initially compressed by hemorrhage or edema which is removed gradually, that collateral circulation opens and restores the blood supply to all or part of the territory originally ischemic and that the clot is recanalized and blood flow reestablished through the occluded artery. In the case of embolism a fourth factor may be added; namely, that the embolus is forced into a side branch allowing the main artery to transmit blood once more. Of these four possible causes two can be excluded on time relations alone. Paralysis developed so rapidly in these attacks and gained its full extent so quickly that edema of the brain around the lesion can be excluded as a significant factor in either the development or resolution of the clinical picture. Again, the rapid recovery clearly was not due to recanalization of clot. There remain, therefore, the possibilities of opening up of collateral circulation and the moving on of clot. Lewis, Rothschild and I [19] described briefly a case of transient paralysis of a limb in which clear evidence of the moving on of an embolus was obtained.[20] In at least 2 of the cases of table 2 this would seem to have occurred. Thus A. N. (case 13), an intelligent schoolmaster, stressed that the recovery from his paralysis was abrupt, being complete in at most a few minutes. This suggests strongly the sudden opening of an artery, as might happen if a clot in the middle cerebral artery had been forced into the mouth of a side branch, freeing the main artery abruptly. Again, the attack in case 15 was probably due to the lodging of an embolus in the left internal carotid artery at the origin of its ophthalmic branch. The clearing of vision and of the paresis can most easily be explained by the moving on of the clot, though it is remarkable that a clot of this size should have produced so little in the way of permanent disability. A similar phenomenon may have happened in case 12. But even in these cases the clot must have finally lodged in, and blocked, some artery. In the remaining cases there is nothing to suggest movement of an embolus, which can scarcely be expected always to occur. In case 16, the most fully observed, the resolution of the paralysis was gradual and the final area of necrosis small and limited to a small area, the putamen. In this case at least the area originally ischemic must have been much larger than the final necrosis and the recovery can only be explained satisfactorily on the gradual restoration of blood flow to the periphery of the lesion by the opening of collateral vessels.

The extent of anastomosis between different orders of cerebral arteries has long been a matter of controversy, arising in part at least from difference in technic. There is now abundant evidence that anastomotic channels exist. Beevor [21] showed that the territory supplied by the middle cerebral artery can be injected through the anterior or posterior cerebral arteries. Pfeifer, Campbell and others [22] have shown in human and cat's brains that the pial vessels, and to a less extent the basal vessels, anastomose at the capillary, arteriolar and arterial level in that order of frequency. Evans and McEachern [22d] have shown that bismuth, injected into the carotid of a monkey just after death, appears in the middle cerebral artery distal to an occluding clip applied to the artery just before death. The anatomic facts and the physiologic behavior of the vessels thus agree in suggesting that the recovery from a localized occlusion of a cerebral artery is at least in part due to restoration of the circulation through collateral channels.

It is clear from the case histories and from inspection of tables 1 and 2 that the cerebral attacks occurring in patients with mitral stenosis and auricular fibrillation are similar in kind and duration to those occurring in severe hypertension. In both there may be a sudden paralysis of cerebral origin which clears completely in an hour or so or clears more slowly leaving a prolonged or permanent disability. There is no clear division in either series between paralysis that is completely and quickly reversible and paralysis with a permanent residuum. In each series an attack that is entirely transient and one with a more permanent residue may occur in a single patient (e. g., cases 3 and 17). Finally in both series examination of the brain long after the attack reveals a small area of necrosis, probably ischemic in nature, near the cerebral area presumably involved in the attack. In 2 cases of hypertension (1 and 3) and 1 case of embolus (16) in which transient hemiparesis occurred, similar lesions were found in the putamen. Even in the embolic case serial sections failed to reveal the vascular occlusion to which the lesion originally owed its cause.

COMMENT

The close similarity clinically and pathologically between the attacks in the two conditions suggests a corresponding similarity in the underlying vascular events. In cerebral embolism the onset of the attack is due to arterial obstruction, in this case by an embolus, and the resolution to restoration of circulation through the opening of collateral vessels. The suggestion is clear that the hypertensive cerebral attacks are likewise due to organic arterial obstruction, also of sudden development, and that their resolution is due to restoration of circulation through dilatation of collateral vessels. This is not a new suggestion. As long ago as 1880 Jackson[23] wrote, "Transient paralysis may be owing to a small clot or to softening from blocking of a small vessel."

P., and McEachern, D.: Circulatory Changes in Cerebral Vascular Occlusion and in Cerebral Cicatrization, ibid. 18: 379, 1938.

The suggestion here made as to the cause of the cerebral attacks in chronic hypertension violates no cardinal principle in vascular physiology and is in harmony with the pathology of hypertensive disease. Thus it is well recognized that in hypertension an artery may suddenly become occluded by clot which forms usually on some preexistent cushion of intimal thickening. It is also known that in hypertension the arterial lumen may be occluded by hemorrhage into the arterial wall or by swelling of the arterial wall as in acute fibrinoid necrosis, but it is not yet known how suddenly these events take place. Any of these forms of closure taking place abruptly would account for the attacks just discussed and which are most frequently concerned can only be told by careful histologic examination of the brain shortly after an attack.

During the present century it has become fashionable to ascribe localized and reversible disturbances of circulation to vascular spasm; in other words, to a strong localized vasoconstriction. In some instances the agent concerned in producing this localized vascular response has been clear, and in these critical examination of the facts has substantiated the hypothesis. Examples are (*a*) acrocyanosis and certain varieties of Raynaud's disease in which the agent is cold, and (*b*) arterial spasm due to trauma of the arterial wall and adjacent tissues. In others it has not been apparent what local vasoconstrictor agent has been at work, and in many of these fuller investigation of the facts has revealed organic arterial occlusion as the essential pathologic event. This is true of other varieties of Raynaud's disease, such as that in which digital necrosis occurs suddenly and bilaterally and that associated with cervical rib.[24] It is true also of certain events associated with disease of the coronary arteries, which like the cerebral arteries were at one time regarded as end arteries. The recent studies of Blumgart, Schlesinger and Davis[25] have shown that occlusion of a coronary artery may produce myocardial infarction, but an artery may also be found blocked in subjects in whom heart disease has never been suspected and in whom the occlusion must therefore have produced no disturbances or only minor ones. The variation in the extent and duration of myocardial ischemia following coronary occlusion must clearly depend on the extent of the collateral circulation, as has been postulated in the case of the brain.

Of all vascular territories the brain is the least likely to show strong localized vasoconstriction, particularly when this is supposed to occur suddenly and without apparent cause. The present paper has shown that organic occlusion of a cerebral artery or arteriole is a more probable cause of the attacks in question. Arguing from the analogy of the coronary arteries, it seems not improbable that occlusion of cerebral arteries may be followed by a variety of phenomena, varying from the classical apoplexy with residual hemiplegia, through the attacks of transient paralysis here discussed, to disturbances so slight as to be recognizable with difficulty. A great deal remains to be done, particularly in the correlation of clinical studies, with the anatomic changes in the cerebral vessels as revealed by the most modern methods. Spasm of the cerebral arteries has been postulated also in migraine and epilepsy. In migraine evidence has been produced that headache is due to arterial dilatation, but the pathogenesis of the aura is still obscure and relevant facts are so few as to make discussion fruitless. The hypothesis that the epileptic attack is due to cerebral vascular spasm has now been very generally abandoned. Nevertheless, Penfield's[26] observations of intense constriction of the arteries of the exposed cortex following an epileptic attack induced by electrical stimulation stand, and are at present imperfectly explained, though it is to be noted that in animals both electrical and mechanical stimulation have produced intense constriction of the pial arteries.

SUMMARY

Hypertensive encephalopathy comprises at least two distinct clinical and pathologic conditions. In acute hypertension or chronic hypertension with recent exacerbation, attacks of headache, vomiting, convulsions and coma are generally due to acute edema of the brain; this edema is less likely to be caused by excessive constriction of the cerebral arteries, as is now commonly held, than by defective constriction, as Traube originally supposed.

In chronic hypertension attacks of localized sensory or motor paralysis of brief duration are probably not due to cerebral arterial spasm but to sudden organic arterial occlusion, for example by a thrombus. The speed and completeness of recovery from paralysis will depend on the size of the final infarct and on its position. The arguments for this hypothesis are: 1. The cerebral arteries have comparatively poorly developed muscular walls. 2. They constrict feebly to known vasoconstrictor agents. 3. In 11 patients with chronic hypertensive encephalopathy no sharp dividing line was found between attacks in which paralysis lasted only a few minutes and attacks from which complete recovery did not occur. 4. In 11 patients embolic occlusion of cerebral arteries produced attacks that were precisely similar in kind and range to those occurring in hypertension.

Amount of Oxygen in Blood.—Normally, 100 cc. of arterial blood contains about 21 cc. of oxygen. Under normal basal conditions, only about 5.5 cc., i.e., about 30 per cent, is removed from the blood as it passes through the capillaries. The remaining 15.5 cc. may be regarded as reserve oxygen which can be called on during exercise or other unusual states to prevent asphyxia of the tissues. The anemic patient, to the extent to which he relies on the mechanism of more complete oxygen abstraction, diminishes his reserve oxygen and sacrifices this factor of safety; the degree of sacrifice would depend on the severity of anemia.—Blumgart, Herrman L., and Altschule, Mard D.: *Blood-the Journal of Hematology*, April 1948.

REHABILITATION OF THE HEMIPLEGIC PATIENT

COMMANDER EDWARD W. LOWMAN, (MC) U.S.N.
Philadelphia

Physical medicine for the rehabilitation of the hemiplegic patient is not a new innovation in the field of medicine. Types of treatment and various regimens have periodically been elaborated in medical publications in years past.[1] Unfortunately, however, as with many aspects of medicine, the widespread application and general appreciation of what can be offered to these patients has been largely deficient. In civilian practice expense has undoubtedly been a major factor in this deficient utilization of physical therapy. Lack of teaching of physical medicine in medical schools and the heretofore scarcity of properly trained technicians and medical specialists in the field have also contributed toward limiting the more general application of adequate rehabilitation.

The urgent demand in service hospitals during the recent war for rapid rehabilitation of sick and injured personnel provided the stimulus for the greatest use of physical medicine and its allied rehabilitation activities ever adopted generally. The results have been widely reported and have not only soundly established physical medicine in the armamentarium of the medical practitioner as the third phase of medicine but have assured its recognition as a separate and potent medical specialty.

With the exigencies of the war period abated and the great number of wounded persons largely rehabilitated, time is now being found to focus attention more definitely on the application of the more intensive regimens for rehabilitation in the treatment of various chronic disabilities. In this broadened application, perspective is governed to a large extent by experiences gained in wartime rehabilitation.

In one naval hospital such an intensive rehabilitation program has been in operation for hemiplegic patients in the past eight months. Prior to the institution of this program, there had been no concerted or continuous effort to provide a systematized regimen for restoring ambulation and independence to these patients. Consequently, at the start the problem was more complex because of chronicity and its attendant deformities, such as atrophy of disuse, apathy and general poor health among most of the patients. The program, nonetheless, was started for this group of patients. As new patients came under observation, they were included promptly in the regimen. This arrangement provided opportunity for critical comparison of results obtained in the two groups of hemiplegic patients. All were hospitalized patients under daily observation; hospitalization was continued as long as necessary without personal expense to the patients. Physical therapy, similarly, was available in the hospital as needed by the patients without consideration of expense.

TREATMENT

In rehabilitation of the hemiplegic patient, the objectives of physical medicine and the measures for directing therapy are twofold, namely, prophylactic and definitive.

During the acute phase of the patient's illness, treatment is solely medical, supplemented by intelligent nursing care.[2] Maintenance of cleanliness; frequent change of positions, insistence on good bed mechanics, sandbags or pillows being used if necessary, are all important in the prophylaxis against trophic changes in the skin and contracture deformities.

The program of rehabilitation is begun from two to four weeks after the onset of acute illness. Initial flaccid paralysis is usually followed within weeks by spasticity; the start of the rehabilitation regimen should precede the onset of this latter phase.

The initial program is prophylactic. Daily passive motion is carried out to prevent the formation of adhesions of the joints and the shortening of muscles, which would predispose to contractures and ultimate deformities. The tendencies toward adduction of the shoulders, flexion at the elbows with pronation of forearms, flexion and external rotation of the hips; flexion at the knee and extension and inversion of the foot are prevented by proper posture and by passive motions of normal range. Local application of heat and massage may be employed after the first week but are not indicated except in cases in which local pain is particularly disturbing or an obstacle to the performance of normal exercise of the joints. The use of Hubbard tanks for reeducation exercises and for early active exercises under water is valuable and is employed almost routinely in this early phase of the reconditioning program. These exercises may be given three to six times a week for thirty minutes each as an addition to the measures already mentioned.

As soon as voluntary motion is possible the patient starts active exercises in bed; these are done several times a day in increasing amounts so that atrophy of disuse may be kept at a minimum. Exercise routines have been well outlined in the literature.[3]

Definite efforts at reambulation should be started early. The period varies from two to eight weeks, but ambulation is physically feasible for the average patient within three to four weeks after his acute illness.

First, sitting in bed is carried out twice daily for several days to readjust the patient to an upright position. He then is allowed to support his weight by placing both feet on the floor in order to regain activity of normal standing reflexes and to relearn weight shifting and balance. After this has been practiced twice daily for several consecutive days, the patient is ready for the gymnasium.

Exercises in the gymnasium must be under the supervision of a physical therapist. In the beginning they consist only of mat exercises, e. g., straight leg raising, overhead extension of the arms, the unaffected arm being used to assist the affected one, abdominal exercises and extension of the back. For uniformity, these exercises are given for five minute periods with or without the assistance of a technician as needed by the individual patient. The exercises are increased in number as tolerated.

From the Department of Physical Medicine, United States Naval Hospital.

[3] Coulter.[1b] Prochazka.[2]

Stand-balance procedures are carried out daily, and the patient is graduated to a mechanical walker as quickly as possible. With the return and increase in muscle power over a period of weeks, he is then allowed to walk between parallel bars and finally to walk with canes. Supervision of gait is important, and patients are taught to practice reambulation procedures before mirrors, with conscious appreciation and correction of errors of which they are guilty.

New hazards are added one by one, and in the course of his rehabilitation the patient must master stair climbing, curb stepping, inclines, beds, toilets, chairs, dressing and undressing and achieve other accomplishments essential to his self sufficiency.

Ultimately it is desirable that canes and other mechanical appliances be discarded entirely. This is of course dependent largely on the degree of damage inflicted at the initial onset of illness and cannot always be done.

Regimens vary for each patient under treatment. Often the resistive exercises is indicated for rebuilding specifically affected muscles or muscle groups. In many instances of more demanding general reconditioning devices such as stationary bicycles and rowing machines can and should be utilized.

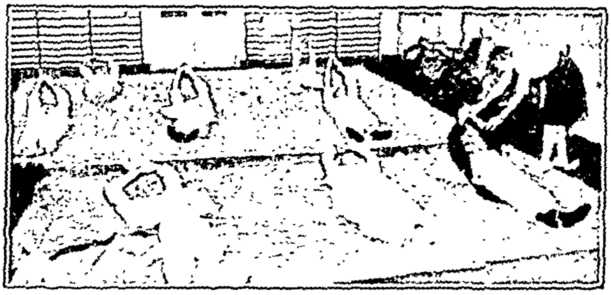

Fig. 1.—Group therapy is a potent stimulus to the morale and cooperation of the patient.

Score card achievement sheets such as those devised for paraplegic patients in Veterans Administration centers[4] may be used as competitive aids to morale.

Group therapy (fig. 1) is important not only in conserving labor but in building morale and a healthy competitive spirit among patients. Exercising on mats in groups and walking in or before groups are invaluable stimuli to the maintenance of good morale and good perspective among these patients, who notoriously are prone to become morbidly introspective and emotional. The importance of this is emphasized when it is remembered that a patient's recovery is almost entirely dependent on his efforts and cooperation and only a small part is the result of supervision and direction. Unless determination and cooperation can be instilled and nurtured, rehabilitation is defeated from the start.

For patients with motor aphasia retraining in speech, carried on under the supervision of the hospital's aural rehabilitation center, is started early and is valuable in expediting and augmenting improvement of this impediment.

REPORT OF CASES

A total of 28 patients (table 1) with hemiplegia which was the result of cerebrovascular accidents were subjected, over an eight month period, to an intensive program of physical rehabilitation. The average age of these patients was 55.2 years. In 13 cases the hemiplegia was on the left side and in 15 on the right.

Chronic Cases.—Eighteen patients initially admitted to the program were chronically ill, having had vascular accidents three or more months previously. The average duration of illness was thirteen and a half months. None of these patients had been subjected to rehabilitation procedures, and all were in the hospital for domiciliary and nursing care. Three were able to stand with support, and the others were either totally confined to bed or were able to be in a wheel chair. All required assistance in getting in and out of bed, in using a toilet or bedpan and in propelling a wheel chair. Morale was extremely and consistently low; they were irritable, querulous and unhappy. After initiation of the program, which lasted an average of one hundred and eighteen and a half days and averaged 95.8 treatments per patient, 5 of the 18 patients were able to walk and were discharged. Reambulation was accomplished in an additional 7 cases. In 3 cases there was no improvement. In the remaining 3 there was slow improvement, which has not yet permitted independent ambulation.

Table 1.—*Results from Rehabilitation of Twenty-Eight Hemiplegic Patients*

Case	Age	Duration of Hemiplegia	Rehabilitation Period, Days	Number of Treatments	Results
			Chronic Cases		
1	57	19 mo.	106	116	Reambulation; discharged

Av.	51.5	5.4 wk.	67.1	41.6	

Case 1.—J. E. K., a 50 year old white man, was admitted to the hospital on Sept. 10, 1945, critically ill with hemiplegia of the right side which was the result of cerebral thrombosis. On his admission no history was elicited because of the presence of aphasia. Examination revealed complete hemiplegia of the right side, moist coarse rales with impaired resonance at the base of both lungs and a blood pressure of 128 systolic and 88 diastolic. There was auricullar fibrillation, with a deficient pulse and weak heart sounds; the liver was palpable 3 fingerbreadths below the right costal margin. Hyperactive deep tendon reflexes were present on the right side, and there was a positive Hoffman sign and an equivocal Babinski sign. The diagnosis on admission was (1) severe cerebrovascular injury, possibly on an embolic basis in view of the auricullar fibrillation and involving an extensive

area of the brain (motor area, left parietal lobe and the internal capsule on the left) and (2) auricular fibrillation on the basis of arteriosclerotic heart disease.

---

[4] "What's My Score?" Veterans Administration Pamphlet 10-10, 1946, p. 36.

The patient improved on supportive therapy, and by October 10 he was able to be out of bed occasionally in a wheel chair. There was slow gradual return of function in the upper part of the right leg, but he was unable to walk or stand and required lifting. As a result of inactivity there developed an external rotational contracture of the right hip and a flexion contracture of the right knee. By July of 1946 there was considerable orthostatic edema of both legs, attributable to long hours of inactivity. During this time he received only spasmodic physical therapy.

On Oct. 22, 1946, a rehabilitation program was begun. At this time the patient was unable to stand or to get to and from his wheel chair. There was an external rotational contracture of the right hip and a 45 degree flexion contracture of the right knee. Abduction of the right shoulder was limited to 90 degrees; muscle function in the right upper extremity was good throughout. The right leg was edematous, and muscle function was fair. Daily reconditioning exercises were begun in the gymnasium. In addition, forceful stretching exercises were carried out twice daily for the contractures. Heat and massage were applied concurrently in the department of physical therapy to minimize secondary soreness and pain. As the knee range increased over a period of weeks to full extension, reambulation was begun. Weakness of the right quadriceps muscle from disuse precluded immediate full weight bearing, and a brace to stabilize the knee was needed for several weeks until the muscle had gained sufficient strength through resistive exercises to enable the patient to support himself. Progress was continuous. One hundred and sixty-nine days after the start of reconditioning the patient was able to walk with the aid of two canes and without braces. He is capable of getting in and out of a chair alone, and of getting to and from a toilet. His gait is slow, but it is sure. The motor aphasia has persisted in degree, but there has been sufficient improvement to permit of meager conversation. There are no residual contractures. The patient is self sufficient.

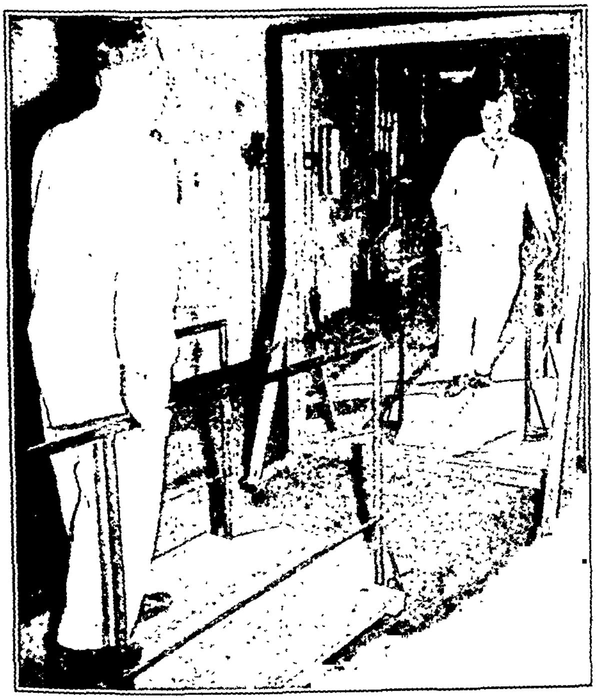

Fig. 2.—The patient in case 1 had been incapacitated for fifteen months prior to the start of the program of rehabilitation; after one hundred and eighty-six days he was self sufficient.

Case 2 (fig. 2).—L. U., a 54 year old white man, was admitted to the hospital on July 12, 1945, with partial spastic paralysis of the left upper extremity and complete flaccid paralysis of the left lower extremity.

In August 1944 the patient first noticed weakness of the first, fourth and fifth fingers of the left hand after a sudden spell of dizziness and fainting; this was followed by an increasing weakness of the left arm and progressive inability to approximate the fingers of the left hand or to perform fine movements of the fingers. Because of the persistence of this weakness he was admitted to the hospital in January 1945 for two weeks' investigation. His systolic blood pressure at this time was recorded as 200 mm. of mercury; diastolic pressure was not recorded. A diagnosis of hypertension with hemiplegia was made at this time.

In March of the same year the patient entered a civilian hospital for further investigation of his disability. Myelograms at this time failed to demonstrate any evidence of a space-consuming lesion in the skull or in the cervical region of the spine; some communicating hydrocephalus was seen. It was noted at this time that the patient was depressed and antagonistic and that he was unwilling to help himself and had assumed a defeatist attitude. He was examined psychiatrically, and it was advised that therapy be directed toward getting him to accept whatever disability he had and to refrain from giving up all his activities by trying to compensate by increased dexterity of his other arm and hand. For about six weeks he was given physical therapy until he was discharged to his home.

On July 9, 1945, the patient lost control of his left foot, and by the next day flaccid paralysis of the entire left lower extremity had developed. On readmission to the hospital on July 12 there was complete hemiplegia of the left side. The blood pressure was 170 systolic and 90 diastolic. Examination of the fundi revealed moderate arteriosclerotic changes, without hemorrhage or exudate. There were hyperactive deep tendon reflexes on the left side, with ankle and patellar clonus, positive Hoffmann and Rossolimo signs and absent abdominal reflexes. It was felt that hypertensive arteriosclerotic disease was the basis for the hemiplegia. In the course of the next fifteen months the patient was subjected spasmodically to physiotherapeutic measures including hydrotherapy, application of luminous heat, massage and occasional ambulation exercises in a walker. There was slight improvement, but during this time there was never inaugurated an intensive systematized regimen for his rehabilitation.

On Oct. 31, 1946, an active program of reconditioning and reambulation was started. At this time the patient could hobble with a cane if assisted; without assistance, he could not stand. One hundred and eighty-six days after the start of the rehabilitation program he had progressed so that he could wheel his wheel chair, get in and out of it unassisted, walk alone with the use of one cane, ascend and descend stairs and get to and from a toilet and in and out of bed. From a standpoint of personal self sufficiency he is independent. There is residual spasticity of both left extremities, with little function in the upper one, but good power and control of the lower.

Fresh Cases.—In 10 of the cases in the series of 28 the cerebrovascular accidents had occurred less than three months prior to initiation of rehabilitation. These were classified as fresh cases. The average interim between the onset of acute illness and the admission to the program was 5.4 weeks. After an average of 67.1 days, during which time they received an average of 41.6 treatments, 9 of the 10 patients were restored to an ambulatory status. Five of this group of 9 were discharged from the hospital. In the tenth case there was improvement, but after seven weeks of treatment the patient was not yet able to walk. Treatment is being continued, and the prognosis is good.

Case 3 (fig. 3.)—D. P., a 57 year old white man, was admitted to the hospital on Oct. 31, 1946, with trichophytosis of the left foot. The patient was known to have diabetes. The infection in the foot healed under treatment, and the diabetes remained well controlled.

On Nov. 20, while still in the hospital, the patient suffered a cerebrovascular accident, which resulted in complete hemiplegia of the left side. For two days he was semistuporous. On the second day it was noted that he could move his left leg slightly. Within ten days the acute phase subsided and spastic hemiplegia of the left side remained. On November 30 physical therapy was begun. The patient received daily treatments in the Hubbard tank, with underwater reeducation of muscles, active exercise and normal range exercises to prevent muscle shortening and contracture secondary to the spasticity. On December 13 hydrotherapy was discontinued and active efforts at reambulation were begun. He was taught standing, balance and weight shifting, and he was then graduated to mat exercising. Within the next month he was using a walker, then parallel bars and finally a single cane. He mastered stair climbing, curb stepping, inclines, beds and chairs, and by March 7, 1947, eighty-four days after the start of his rehabilitation, he was completely self sufficient and was discharged from the hospital. On his discharge there was still complete paralysis of the left upper extremity and spasticity of the lower extremity, but muscle power and control were excellent.

CASE 4.—W. T., a 49 year old white man, was admitted to the hospital on Feb. 1, 1947, acutely ill from a cerebrovascular accident.

For five years prior to his admission the patient had had hypertension and had been under the care of his physician. Two weeks prior to his admission he began having blackout spells and was confined to bed. One week later there developed headaches, *progressive motor aphasia and weakness of the right extremities*.

FIG. 3.—The patient in case 3 was initiated early into the program, *was graduated to active reconditioning within six weeks after the occurrence of the cardiovascular accident and was discharged as rehabilitated after eighty-four days.*

On admission to the hospital the patient was acutely ill, dyspneic and stuporous. His blood pressure was 165 systolic and 110 diastolic. There were diffuse coarse rales throughout both pulmonary fields and complete hemiplegia of the right side, with increased deep tendon reflexes and a positive Babinski sign on this side. The patient was aphasic. During the next month he improved slowly. On March 3 rehabilitation was started. Within the ensuing thirty-eight days he was completely ambulant, without need of canes or other supports. There was good return of function in both right extremities. The aphasia improved so that he could carry on a laconic but intelligible conversation. He was discharged, ambulatory and self sufficient, on April 26.

COMMENT

In the initiation of an active regimen for patients with proved defective vascular systems, there was naturally considerable apprehension as to the limits of exercise which might safely be tolerated. Accordingly, an effort was made to evaluate the demands of the exercises to be employed (table 2). Individual patients were subjected to the exercises, and the blood pressure and pulse were checked just prior to and immediately after each procedure. Only one exercise a day was done by each patient, and a rest period of five minutes preceded each. Similarly, combined continuous exercises for periods of twenty minutes were performed by the patients and the blood pressure and pulse recorded. It was surprising to note the apparently excellent tolerance of these procedures by all patients and the relatively minor effect on their vascular mechanisms. However, despite the tolerance of even the combined twenty minute exercises, patients were never subjected to exercise for a period of this length in the gymnasium but were permitted to rest between procedures. No difficulties were encountered among the 28 patients at any time as a result of the reconditioning procedures.

Cooperation on the part of the patient, fostered by his desire to regain his independence, is the greatest factor in assuring the success of his ultimate rehabilitation. Normally the hemiplegic patient's conception of his prognosis is a gloomy one based on lay associations and observations. Hobhouse[18] has pointed out, however, that if the medical attendant has clear ideas on the subject, is aware that the outlook for uncomplicated hemiplegia is potentially good and can convince the patient of this fact he will appreciably improve the prospect. Fortunately, morale is rather easily stimulated ; this is a contrast to younger patients wounded in war whose youth, immature perspective and undue desire to compensate at times rendered them less cooperative. Because of a mature perspective, the hemiplegic patient appreciates more fully the limitations imposed by his disability and is accordingly more earnest in his desire to recoup his loss.

The extent of ultimate functional return is dependent primarily on the degree of damage wrought by the vascular accident. Secondarily, however, the expeditious and intelligent direction of the program of rehabilitation markedly augments the favorable outlook. The treated patient always shows better results than the untreated patient, and delay modifies in direct degree the success of the final result.

By and large, the job is one of salvaging all innervated muscle through reeducation and the building of muscular power to a maximum functional level with remedial exercises.

The least return of function occurs always in the fingers and wrist, with greater return proximally toward the shoulder. In a large percentage of cases there is minimal functional return throughout the upper extremity. The greatest return occurs always in the proximal part of the lower extremity, with loss graduated distally. In no case in this series has loss of function in the lower extremity been complete or sufficiently extensive to preclude the possibility of reambulation. In the 3 chronic cases in which reambulation was not effected, the hindering factor was mental deterioration and not paralysis. Hobhouse[18] expressed the belief that the greater return of function in the lower extremity as compared with the upper is the result of the fact that the lower extremities must be used together to be of functional value whereas this is not true of the upper extremities. He further stated that the pathologic damage to the innervation productive of the hemiplegia is no greater in the upper extremity than in the lower but that the relative deficiency in return of function in the arm is a manifestation of disuse. He advocated early use of the upper extremity, even to the extent at times of putting the unaffected arm in a cast, and reports good results in his cases. The frequently poor return of function in upper extremities in this series is therefore possibly due to inadequate therapy.

In a comparison of the results of treatment among the 18 chronic cases and the 10 recent cases of hemiplegia, it is of interest to note that the time necessary to bring about reambulation in the recent cases was roughly half as long as that required in the chronic cases. It is also noteworthy that no failure occurred when reconditioning was begun promptly while among the chronic cases no progress was made in 3 and in 3 others progress was slow despite protracted periods of treatment. Reambulation was brought about in 90 per cent of the cases observed early as compared with 66 per cent of the chronic cases. This may not be wholly a valid comparison, since among recent cases a certain percentage of spontaneous recoveries should normally be expected. On the other hand, the absence of failure cannot be minimized.

* All procedures were preceded by a five minute rest period.

Among the chronic cases there were a few in which reambulation was accomplished relatively soon after the start of reconditioning. This can be attributed to (1) a less degree of initial neurologic damage and/or (2) greater activity and therefore greater personal rehabilitation by the individual patient.

In directing the physical reconditioning of the hemiplegic patient, self sufficiency is the basic objective desired and adeptness a secondary consideration to be striven for but not insisted on. Training in posture and gait and the prevention of bad habits are important and must be closely guided. When there has been minimal permanent damage, a rhythmic and coordinated gait is completely possible and attainable through careful training. In a great many cases, however, ambulation is really "self propulsion" rather than rhythmic walking. This "propulsion" may well be the maximum that is possible in the face of the residual damage, and in such cases so long as it meets the criterion for self sufficiency it must be considered satisfactory. A patient may continue to need one or two canes indefinitely. Circumduction types of walking have been condemned by many writers. However they often constitute the patient's maximum adeptness and as such should be accepted as satisfactory if self sufficiency is thus attained. The same principle applies to stair climbing, dressing and undressing, getting into and out of a bed and to and from a toilet and the numerous other hazards which must be mastered in the process of rehabilitation.

Among the chronic cases, in which the period of disability averaged thirteen and a half months when rehabilitation was begun, the immediate major problems were the contracture deformities and the atrophy of disuse. Initially the contractures had to be corrected through stretching exercises. To be effective stretching must be forceful and at least temporarily painful, and it must be done regularly several times daily. Various physiotherapeutic measures such as heat, diathermy, hydrotherapy and massage are valuable adjuncts in minimizing consequent soreness. The most commonly encountered deformities in this series were those secondary to contractures of the pectoral hip external rotator, hamstring and gastrocnemius muscles.

Generally there are few indications for the use of braces. Caliper types of braces are of value in the maintenance of progress gained by stretching exercises in cases in which there are contractures. Foot-drop supports in the form of figure-of-8 straps or spring dropped-foot braces are indicated in cases in which gross distortion of gait may be benefitted or in cases in which weakness of the ankle permits outward rolling of the foot with weight bearing. Occasionally when there is noted weakness of the quadriceps muscle it is helpful to employ locked knee braces to expedite reambulation; these braces are retained only until the strength of the quadriceps has been rebuilt through concurrent resistive exercises.

When there is poor return of function in an upper extremity, the orthostatic pull of the flail arm often is productive of pain in the shoulder. Local physiotherapeutic measures are of help. The use of a supportive sling may become necessary, but this is undesirable because immobilization not only retards return of function but constitutes an additional hazard for the patient.

The use of transcranial diathermy[5] and various electrical currents[6] has not seemed warranted from the reports in the literature. Except for therapeutic exercise, the prolonged and usually empiric use of physiotherapeutic measures is rarely indicated. Too often injudicious use constitutes abuse and effects only a diversion of attention from the full use of intelligently administered therapeutic exercise, which is the specific agent in accomplishing the patient's rehabilitation.

Neostigmine was given to many patients with spasticity; the results obtained were inconsistent. In some cases it appears to provide relief of pain, and therefore it is worthy of trial.

Retraining in speech has been of value to aphasic patients. Ideally this should be done by a speech therapist. However it has proved satisfactory to have the program carried on by volunteer hospital workers under the direction and supervision of a therapist, an arrangement necessitated by the local shortage of trained speech therapists.

SUMMARY

1. Twenty-eight patients with hemiplegia were subjected to an intensive program of reconditioning and rehabilitation. Eighteen of these patients had become chronically incapacitated since their cerebrovascular accidents, which had occurred on an average of thirteen and a half months prior to initiation of rehabilitation. The illness in the remaining 10 patients was of relatively recent onset, since they had sustained their cerebrovascular accidents on an average of 5.4 weeks and not longer than eight weeks prior to the start of rehabilitation.
2. In 66 per cent of the chronic cases reambulation was accomplished after an average period of one hundred and eighteen and a half days. Improvement had occurred in an additional 17 per cent. In the remaining 17 per cent no benefits were obtained because of mental deterioration and emotional instability of a degree which precluded adequate cooperation.
3. In 90 per cent of the fresh cases reambulation was accomplished after an average period of 67.1 days. Improvement occurred in the remaining 10 per cent. Among this group there were no failures.

CONCLUSION

The early, intensive and intelligent use of physical medicine, with emphasis on therapeutic reconditioning exercises, assures a potentially good prognosis in the rehabilitation of patients with uncomplicated hemiplegia.

The Red Cells are Non-Conductors.—The erythrocyte constitutes an almost perfect non-conductor of electrical current, in which characteristic it is almost unique among tissues. Stewart, Oker-Blom. Wilson and others have utilized this characteristic to make possible the determination of the hematocrit and mean cell volume by electrical techniques—Hirsch, Fred G.; Wood, Lloyd A.; Ballard, William C.; Frey, Constance, and Wright, Irving S., from an address given April 29 at the Clinical Research Meeting of the New York Academy of Medicine.

REVASCULARIZATION OF HEART BY GRAFT OF SYSTEMIC ARTERY INTO CORONARY SINUS

CLAUDE S. BECK, M. D., EUGENE STANTON, M. D.,
WILLIAM BATIUCHOK, M. D., AND EUGENE LEITER, M. D.
Cleveland

The first experiments to improve the arterial circulation to the heart were carried out by one of us (Claude S. Beck) in 1932. At that time the idea of improving coronary circulation by operative methods was a radical departure from established medical thought. A serious study of this subject was undertaken and several thousand operations were done on dogs during the next ten years. The results of these studies cannot be given here, but a general statement can be made to the effect that the circulation to the heart was improved by operative methods.[1] The degree of benefit produced by operation was measured by mortality after ligation of a major coronary artery in an operative group as compared to that in a normal control group. The size of the infarct following ligation of a coronary artery was also an index of benefit. That the heart was protected by operative methods was shown by a reduction in mortality of 50 per cent after ligation of a major coronary artery. Also the infarct was smaller in the operative group than in the control group. In some specimens an infarct did not develop after the descending ramus of the left coronary artery was ligated. In a normal heart an infarct always developed after ligation of this artery provided the animal survived the ligation. Thirty-seven patients with severe coronary artery disease were operated on. The results obtained after operation were beneficial. The clinical results corresponded with the results obtained in the experimental studies.[2]

In this work revascularization of the heart was produced in two ways. One was by the production of inflammation on the surface of the heart which in time led to the development of anastomoses between coronary arteries. These intercoronary communications brought about a more equitable distribution of blood in the myocardium and aided in the prevention of trigger zones in the heart which so frequently are responsible for ventricular fibrillation and death. The second method for improving blood supply was by grafting vascularized tissues on the heart with the expecta-

From the Department of Surgery, Western Reserve University, and the University Hospitals. This work was aided by grant R. G. 399 of the National Institute of Health, United States Public Health Service.

tion that blood vessels would grow across from the graft to the heart.

Further application of this work would have been carried out on patients between the years 1942 and 1945 had it not been for the war. During this period, however, a new approach to the problem of revascularization of the heart was beginning to come into existence. This development is the subject of this report.

In 1937 Gross, Blum and Silverman[3] reported an important research on the coronary sinus in dogs. These authors ligated or partially occluded the sinus and found that blood escaped from the heart into the four chambers of the heart. In their hands the mortality following this ligation was 42 per cent. They found that ligation of the sinus produced extensive and abundant dilatation of the intramyocardial collateral channels. Ligation of the sinus was advocated by them as a method of treatment for occlusion of a coronary artery. Physiologic studies were carried out on the sinus by several investigators[4] and the conclusions in general were less favorable than those of Gross and his associates concerning ligation of the sinus for coronary artery disease. Gregg and Dewald found that the pressure in the coronary sinus rose immediately after ligation to the level of aortic pressure. They found the contour and time relations of the venous pressure curves to resemble closely the curves obtained from the coronary artery. Thornton and Gregg studied the problem after the coronary sinus had been occluded thirty days. They found that the pressure in the sinus had practically returned to normal levels. No doubt the channels within the myocardium opened so that blood could escape more readily into the cavities of the heart.

In 1941 Beck and Mako[5] repeated the experiments of Gross, Blum and Silverman. They reduced the mortality of occlusion of the coronary sinus to about 2 per cent and found that occlusion of the sinus had some beneficial effect against occlusion of the descending ramus of the left coronary artery. They did not believe the benefit was great enough for application to patients.

While this study was in progress a query was made in our research laboratory to one of us (C.S.B.) by J. T. Roberts concerning the possibility of making an arteriovenous fistula in the heart. In 1943 Roberts, Browne and Roberts[6] reported on 14 dogs in which arterial blood was brought to the myocardium by a glass cannula connecting the coronary sinus with the brachiocephalic, subclavian or innominate artery. The coronary vein became distended, pulsatile and arterial in color. These dogs survived under conditions of acute experiments from 10 minutes to 26 hours even after ligation of coronary arteries. These authors stated that examination of myocardium revealed a complete injection of the capillaries after dye was injected into the coronary sinus.

In 1945 Blalock and Taussig[7] reported on the treatment of the tetralogy of Fallot by anastomosis of subclavian artery to pulmonary artery. Independently Gross[8] and Crafoord[9] resected a segment of aorta for coarctation and Clagett[10] transplanted subclavian artery into aorta beyond the constricted segment of aorta. Fauteux[11] reported on his operation for sclerosis of the coronary arteries in 15 patients. This operation involved ligation of the magna cordis vein and Fauteux showed that the human heart could tolerate occlusion of this vein. An additional aid in our work was the "vitallium" cannula of Blakemore and Lord.[12] Although this cannula was not successful in our work, it served a purpose in getting us started. The clamp devised by Potts, Smith and Gibson[13] for anastomosis between aorta and pulmonary artery is being used by us to graft a new branch from aorta to coronary sinus. These advances in surgery--and no doubt there are others that have not been mentioned—have contributed their part to the work reported here.

TECHNICAL DEVELOPMENT OF THE OPERATION

This study was begun Feb. 6, 1946. During the following two years approximately seven hundred operations were done on 350 dogs. By April 20 the first patent anastomosis was obtained after operating on 67 dogs, but this anastomosis, like many others that followed, became occluded by formation of thrombus later on. Eighteen months were spent on the project before we had any definite evidence that the anastomosis was beneficial, and it was almost two years before the first patient was operated on.[14]

Repeated operations were necessary. This work required strong, vigorous dogs free of diseases. Distemper, pneumonia, animal tics and malnutrition were conditions that retarded progress in this research. Indeed, it was not possible to make a test of benefit for the operation during the first year of our work because of these conditions. In the second year of this work a grant from the United States Public Health Service made it possible to work under satisfactory conditions. We found that the bull terrier was the best breed of dog for this work. The operative work required the best in asepsis, mechanical respiration and oxygenation. Three to five hours of anesthesia were required for the anastomosis. We lost a number of dogs because of imperfect absorption of carbon dioxide in a closed system of anesthesia.

Can the Coronary Sinus and its Tributaries Tolerate Arterial Pressure?--During the first year of the work we had about 20 instances of hemorrhage into myocardium. This complication occurred after the sinus was ligated and also after anastomosis was made to the virginal sinus. In the second year of the work this complication did not occur. This complication was due to the fact that we were using sick dogs in poor nutritional condition. This complication disappeared after diseases were stamped out of our kennel and after we began to feed the dogs meat and liver. In healthy dogs we can say that the coronary sinus and its tributaries can tolerate arterial pressure. More recently we used heparin and "dicumarol" during and after operation. We obtained 1 specimen in which there was hemorrhage in the wall of the left ventricle. The hemorrhage was not pronounced and probably was not the cause of death in that experiment. It would appear that the possibility of hemorrhage exists when these agents are used.

The Coronary Sinus in the Dog.--The coronary sinus varied somewhat in different dogs. In many animals the sinus was delicate and for surgical manipulation was like wet tissue paper. In our hands, after two years of intensive work, anastomosis could not be done on the virginal sinus when it was so delicate and thin. In many instances, however, anastomosis could be done satisfactorily. Anastomosis always required intensive concentration. The tributaries to the sinus present a problem. There were two types of tributaries to the sinus. One was the type of relatively large vein which lay beneath epicardium and entered the inferior aspect of the sinus. The other type was a vein of hairlike size that could scarcely be seen that entered the floor of the sinus. The circumflex coronary artery was inferior to the sinus; right auricular wall was superior to the sinus; auriculoventricular node was near the ostium of the sinus. The approach to the sinus was a problem. We approached it from the right side of the chest for most of our experiments, but more recently we have approached it from the left side.

We observed that certain changes took place in the sinus after the sinus was ligated. Ten days to several weeks after ligation the distention of sinus was less pronounced. The wall of the sinus had become thicker so that the sinus could be manipulated with a greater degree of safety. We used preliminary ligation of the sinus as an aid to anastomosis. The optimum interval between ligation of sinus and anastomosis of artery to sinus was ten days to two weeks. We had about fifty failures because the interval was longer. The sinus had become small and the wall rather fibrotic. Ligation of sinus became the first step in the operation in most of our work. Ligation of sinus during the first year of the work had a mortality of about 15 per cent. In the second year of the work the sinus was ligated in 78 consecutive dogs without a death. This difference in mortality was due to the health of the dogs and showed how scientific observations could be influenced by such extraneous factors. The fact that the sinus was ligated in 78 dogs without mortality indicated that the sinus and its tributaries could tolerate increased pressure in the venous system.

The Coronary Sinus in Man.--The sinus in man varied considerably from the sinus in the dog. In man the sinus was a larger and stronger structure. The diameter was almost 1 cm. The wall was thicker. It could be much more readily manipulated. The hairlike tributaries were not found. The sinus was not so deeply buried in myocardium. It could be dissected away from the myocardium for about 1 cm., and this dissection appeared to be safe.

Concerning the Artery for Anastomosis in the Dog.--Attempts to use various arteries were made. The internal mammary, the brachiocephalic and the subclavian arteries were either too small or too short for anastomosis to the sinus. The only artery that could be used was the common carotid artery. This artery could be taken almost always without cerebral complications provided it were taken below the bifurcation. Convulsions and hemiplegia frequently occurred if ligation were done above the bifurcation of the artery. The carotid artery was dissected down to its origin from the brachiocephalic artery. It was turned down from the neck in a direction posterior and lateral to the brachiocephalic artery. A special instrument was made to carry it down from the neck to the heart. The entire dissection was made from the neck. The wound in the neck was closed before the chest was opened. When the chest was opened the instrument was located by the finger and brought out with the artery. For anastomosis the artery was cut on the bias in order to increase the size of the stoma.

[14] Beck, C. S.; Revascularization of Heart, progress report, Sept. 13, 1947, Surgery Study Section, United States Public Health Service. (This report covered our work from Feb. 6, 1946 to Sept. 1947).

Concerning the Artery for Anastomosis in Man.—The carotid artery is an important artery in man. Ligation may be followed by cerebral complications. This artery is larger than the normal coronary artery and therefore was larger than necessary for our operation. Its use would necessitate the removal of a piece of clavicle to get exposure of carotid artery where it comes off the aorta. The dissection in the neck would add considerably to the magnitude of the operation. For these reasons we did not care to use this artery. However, there was no other artery that could be used. The internal mammary artery was too small; the subclavian artery and the vertebral artery were not accessible. There was no artery in the abdomen that could be used.

This was a serious problem. Fortunately we were able to solve it. The solution was to make a new branch from the aorta. We used a segment of artery in most of our experiments. A segment of vein might prove to be satisfactory. The length or graft necessary in the dog was 5 cm. For the anastomosis in man the distal end of the brachial artery seems to be of proper size. We believe that this segment of artery can be taken without seriously crippling the hand.

The Anastomosis to the Coronary Sinus in the Dog.—The epicardium was incised for about 1 cm. just above and below the sinus as it entered the atrium. Gentle dissection allowed the sinus to stand out. A special curved ligature carrier was placed between sinus and coronary artery and directed under sinus coming out, in or through auricular wall just above the sinus. The carrier was introduced at two points about 1 cm. apart. The sinus must not be punctured or injured. The first passage of the instrument carried a double piece of silk. The silk was cut and disengaged from the carrier. One piece was used for a ligature. The other piece of silk, which was long, was placed in the carrier and passed between sinus and coronary artery, under sinus and emerging through or in auricular wall superior to sinus. The silk after it emerged was cut. We than had a mattress suture under 1 cm. of sinus together with a piece of silk on each end of the segment. After the mattress suture was tied and after each piece of silk was tied we had the segment of sinus isolated so that there was no blood flowing through it. Two arterial sutures were placed in the wall of the sinus. These were gently held up and sinus wall was cut for about 5 mm. The sinus was washed with a solution of heparin. The artery or vein was brought into position. Four cardinal sutures were placed between sinus and graft, one on each end of the open sinus and one midway on each side. These sutures were everting mattress sutures. They were tied. The anastomosis was completed by a continuous everting suture. The mattress suture was removed as was also one suture occluding the sinus. The occluding suture on sinus between anastomosis and entrance into right auricle was left as an occluding suture (fig. 1).

The Anastomosis of Arterial Graft to Aorta.—We used a segment of carotid artery in the dog because it was more readily available than any other artery large enough for anastomosis. The aorta was dissected free. Two intercostal arteries were ligated and cut. Care was taken to avoid injury to thoracic duct. The Potts, Smith, Gibson clamp was applied to aorta. This clamp made it possible to open aorta and at the same time allow blood to flow through aorta. The aorta was incised for a distance of 5 mm. The incision was made above the compressed margin of the aorta. The graft was cut on the bias. A horizontal, everting, continuous mattress suture was used. The suture was begun at one end. Each suture was properly spaced (fig. 2). Care was taken that the needle did not penetrate aorta twice at one point, as this could lead to hemorrhage. The anastomosis of free arterial graft to aorta was done before the anastomosis between artery and coronary sinus was carried out.

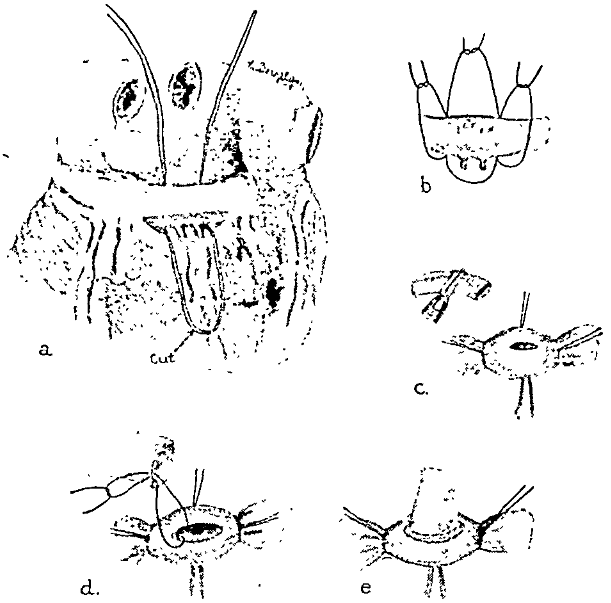

Fig. 1-Anastomosis in the dog. *A*, dissection of sinus. *B*, isolation of segment of sinus. *C*, sinus opened. *D*, one cardinal suture placed between arterial graft and sinus. Sutures are everting of mattress type. *E*, anastomosis is complete. Hemostatic ligation and suture have been removed.

OBSERVATIONS AFTER ANASTOMOSIS

Concerning the Heart.—When the transplanted artery was opened after anastomosis had been made, several observations were noted concerning effect on the heart. The sinus became distended and frequently showed pulsation. The veins became pink. The heart seemed to improve in color. The heart was firmer to the touch. The beat remained regular. It was noted by each of us that the heart seemed to take a more forceful beat after the transplant was opened. A heart which was not doing well during anastomosis did better after the anastomosis was opened. Other factors such as dislocation of the heart might have been responsible for this. Dislocation was released after transplantation was finished. Electrocardiograms did not show any change at the time the anastomosis was opened or later on. The heart did not dilate. Hypertrophy did not develop in those experiments in which sinus was totally occluded between anastomosis and auricle. Cardiac failure did not develop in any experiment.

Number of Patent Anastomoses.—"Vitallium" Cannulas: During the first nine months of the work we used "vitallium" cannulas for the anastomosis. The artery was placed through the cannula, cuffed back over the cannula and held in position by a ligature. The cannula and artery were introduced into the sinus and held in position by a ligature around the sinus, artery and cannula. Our records showed that there were fifteen patent anastomoses when the dog died or when the dog was killed. The time interval was up to sixty-nine days in 1, over a month in 5 and over a week in 12.

Fibrosis occurred in the segment of artery within the cannula. This process seemed to be progressive. Animals with patent anastomosis during the early postoperative period later on showed occlusion. This method of anastomosis was given up.

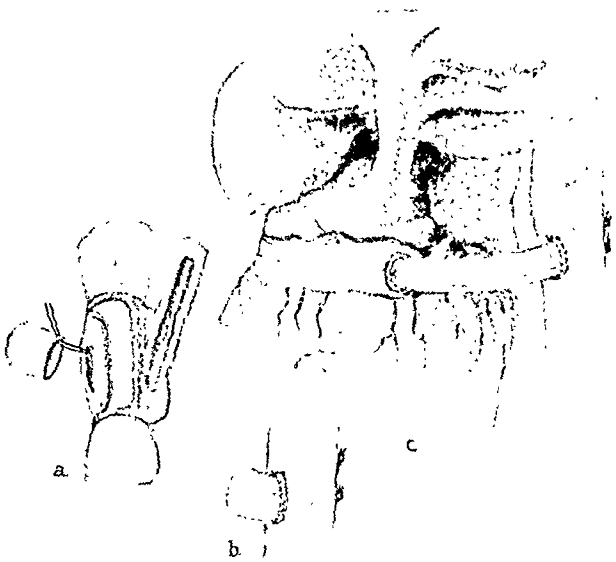

Fig. 2. Anastomosis in the dog. *A*, anastomosis between aorta and arterial graft; Potts, Smith, Gibson clamp on aorta; aorta opened; one everting suture in place. *B*, anastomosis between arterial graft and aorta completed. *C*, new branch from aorta to coronary sinus.

Suture Technic: The "vitallium" cannula served a purpose in getting us started on the research at a time when we did not believe the suture technic was possible. Our records showed that there were thirty or more patent anastomoses with the suture method. The longest period between anastomosis and the time when the dog was killed for the specimen was four and one-half months. Thrombosis and occlusion occurred in many specimens. We believe that this was related to trauma of the operation. As a rule we could predict at the time of operation whether the anastomosis would remain patent. Anticoagulant agents were not used for this work. More recently they have been used.

Health of Dog after Anastomosis.--As a rule the postoperative period was uneventful after anastomosis was done. The first dogs to go through the operation were watched with great interest to see how the heart would stand the increased circulation. The dogs tolerated the anastomosis well. They were up as usual the following day and, after several days, they were as active as other dogs. Circulatory failure was not observed in any experiment. Some of the dogs had murmurs; others did not. The electrocardiogram was essentially normal.

MEASUREMENTS OF BENEFIT

These were made by determination of mortality following ligation of descending ramus of left coronary artery at its origin in one step and also by determination of size of infarct following this ligation.

Mortality.—The following operations were done in sequence. 1. The descending ramus of the left coronary artery was dissected at its origin and a piece of silk was placed around the artery, but it was not tied and the artery was not constricted. This piece of silk was an aid to ligation of the artery later on. 2. Complete or partial ligation of the coronary sinus was done one or two weeks after the first operation. 3. Ten to fourteen days after ligation of the sinus, anastomosis between the carotid artery and the coronary sinus was carried out. 4. Two weeks later the coronary artery was ligated as referred to in 1. The silk thread helped in the isolation and ligation of the artery. It was completely occluded. After ligation of the artery the dogs were kept for a period which varied from sixteen days to four and one-half months. Two series of dogs of 10 each are presented. In one series the anastomosis was patent. In the other series the anastomosis was completely occluded by thrombus. In the control series with blocked-off anastomosis death occurred in 7 and recovery in 3. Four died within one hour after ligation of the artery; 2 died within the first twelve hours and 1 died forty-eight hours after ligation. In 50 normal dogs with this artery ligated the mortality was 70 per cent[1d] and in 57 dogs with ligation of the sinus at one operation and ligation of the artery at a subsequent operation the mortality was 61 per cent.[5] In the series with patent anastomosis the entire group of 10 survived the immediate effect of the ligation; 1 died eight days later; 1 died thirteen days later; 8 recovered.

Infarcts.--The infarcts were observed. The 3 specimens of the control group showed destruction of myocardium by observation of the surface of the heart. None of the patent group showed such evidence of destruction on the surface of the heart. The specimens were cut. Each of the control specimens showed extensive destruction of myocardium. None of the group with patent anastomosis showed extensive destruction of myocardium. In 4 specimens there was no infarct. In the other 6 specimens including the 2 that died the destruction was limited to scattered areas of a few square millimeters. In no specimen of the group was there extensive destruction involving entire thickness of myocardium. These results showed that the anastomosis was beneficial. They showed that the degree of benefit was definite. The anastomosis made it possible to ligate a major coronary artery with no immediate mortality and with little or no destruction of heart muscle.

INJECTION OF SPECIMENS

A considerable quantity of blood may pass through an arteriovenous fistula. Specimens of hearts were examined in reference to this possibility. We examined venous tributaries in the normal heart, in the heart after occlusion of sinus and also in the heart after anastomosis had been made. It was obvious that adjustments had to occur after the sinus was ligated. Blood escaped from the heart through other channels. There were two exits for this escape of blood. One was through the intramyocardial channels that empty into the four chambers of the heart. The other was a system of superficial veins that drain blood from the coronary sinus system into the right atrium. In the normal heart of the dog these superficial veins were found both anteriorly and posteriorly over the right ventricle. After occlusion of sinus these veins were usually increased in size and number. After anastomosis these veins were approximately the same as after occlusion of coronary sinus. Twenty-two cleared specimens with patent anastomosis were examined. Arteries and veins were injected in these specimens. In 2 specimens these veins were fairly large and numerous; in 20 specimens these veins were not larger or more numerous than in specimens after occlusion of the sinus.

Our conclusion was that in most specimens the superficial channels draining blood away from the coronary sinus system were of no special significance. The possibility existed, however, that these veins can develop, and in 2 specimens these veins did develop. Should these veins drain off any significant quantity of blood it would be possible for these to reduce the flow through the myocardium and thereby impair physiologic benefit of the operation. If this complication should develop, it would be possible to ligate these veins at the time of anastomosis. In the human heart there were no superficial veins anteriorly, but posteriorly one, or two or three channels were found. These channels will be ligated at the time of anastomosis in the human patient.

It was possible to obtain information on bloodflow in both the superficial channels and also in the intramural channels by injection of blood into the coronary sinus in the normal heart, into the coronary sinus after ligation of the sinus and also into the sinus after anastomosis to an artery had been done. The heart was removed and injection performed immediately. The dog's own heparinized blood was used. The pressure for injection was 120 mm. of mercury.

Normal Heart.—A cannula was placed in the coronary sinus and one was also placed in the left common coronary artery. When blood was injected into the sinus an average figure of 9 cc. per minute was recovered from the coronary artery. No blood was obtained from the right coronary artery.

After Occlusion of Coronary Sinus.—The sinus was ligated and several weeks later injection of blood was done as in the normal specimen. The average amount recovered from the artery was 22cc. per minute.

Patent Anastomosis between Carotid Artery and Coronary Sinus.—In 10 specimens the average amount of blood that was injected into the transplanted artery was 60 cc. per minute and the average amount that was recovered from left coronary artery was 6 cc. per minute. The greatest inflow into transplanted artery was 175 cc. per minute. When the injection was reversed the average amount that entered the left coronary artery was 100 cc. per minute and only 1 cc. was recovered from the transplanted artery.

Comment.—It can be stated that there are communications between the venous side of the circulation and the arterial side of the circulation which in the dead specimen allowed blood to flow in a retrograde direction. A larger quantity of retrograde flow was recovered after the sinus had been ligated as compared to figures in the normal heart. After patent anastomosis of the carotid artery to the sinus was made, it is significant that the inflow through transplanted artery to vein was not excessive. The inflow was about the same as the inflow into the coronary artery. This situation does not exist in arteriovenous fistulas in other parts of the body where the pressure on the venous side is comparatively low and large quantities of blood flow through the fistula. In this respect anastomosis of artery to coronary sinus differs from all other arteriovenous fistulas. Because inflow of blood into transplanted artery and inflow into the coronary artery were about the same, it would appear that the resistance to flow in the vascular bed of the myocardium was about the same whether the blood entered by way of the vein or by way of the artery. That blood was not freely siphoned off into the cavities of the heart was, indeed, a favorable condition in terms of application to patients. There appeared to be no wide open fistula effect either within the myocardium or in the superficial veins draining blood directly into the right atrium. Long term experiments may provide different results. These should be done.

Specimens with Patent Anastomosis and Partial Occlusion of Sinus.—It was routine procedure to place a ligature of silk around the sinus at a point between the ostium of the sinus and the anastomosis between the artery and the sinus. If complete occlusion of the sinus were not produced then an arteriovenous fistula would develop into the auricle. This occurred in 8 of our specimens. An opening was found when blood was injected into the transplanted artery. The amount of blood escaping through this opening, a pressure of 120 mm. of mercury being used, was 65, 92, 118 and 225 cc. per minute. In 1 or 2 of the specimens the heart appeared to be questionably enlarged. It is possible to prevent this complication by placing two ligatures around the sinus and dividing the sinus between ligatures. It would appear that a small fistula might have therapeutic value. The increased flow through anastomosis might reduce the possibility of formation of thrombus. It is a point to bear in mind that a temporary fistula might have therapeutic value.

APPLICATION TO PATIENTS WITH SCLEROSIS OF CORONARY ARTERIES

At the end of two years of experimental study we were ready to apply the operation to patients. During the past two years approximately 100 patients with coronary artery disease had come to one of us (C.S.B.) for operation. These patients were advised to wait until this new operation was developed. Recently the names of 8 patients were selected to come into the hospital for study. Of these 8 patients, 2 had died. The first patient of the group who was admitted to the hospital for study had a markedly dilated heart and appeared to be threatened with failure. He was not accepted for operation because the risk appeared to be too great. We believe that a failing heart would be benefited if the anastomosis could be done. We believe that the heart will improve when arterial blood is turned into the heart. Irreversible damage existing in the heart will remain as such and no doubt will influence the clinical result after operation. The undamaged muscle, however, should be given restoration of function by the operation. The question arises, therefore, whether patients who have signs of failure should be operated on. It would appear to us that any salvage out of this group would be on the credit side even though the mortality of operation reached a figure as high as 50 per cent. If this group of patients showing circulatory failure is accepted for operation it would appear reasonable to keep this group separate for statistical purposes. We believe that there should be some salvage in this group and the only way to find out is to operate on a number of them.

Operation on Patient Jan. 27, 1948.—The operation was carried out on a patient who had had severe coronary disease over a long period of time. He was almost incapacitated. A graft of brachial artery was used between the aorta and the coronary sinus. The segment of brachial artery had some atheromatous deposit in it. The anastomosis was done as described in the experimental work. The patient tolerated the procedure and the results will be reported at a future date.

CONCLUSIONS

A systemic artery or a new branch from the aorta was grafted into the coronary sinus in dogs. The technical aspects of this operation were developed. This anastomosis was beneficial. The degree of benefit was marked. After this anastomosis was done it was possible to ligate the descending ramus of the left coronary artery at its origin in one step with no immediate mortality and with little or no destruction of heart muscle.

After anastomosis was made between artery and sinus, the specimens did not give significant evidence of excessive drainage of blood by way of intramural channels or by way of superficial veins that empty into the right antrium. Additional evidence on drainage channels in long term experiments is desirable.

This operation was applied to 1 patient who had severe coronary artery disease. A new branch from the aorta was made with a segment of brachial artery. The patient tolerated the operation. The clinical results will be reported later.

PSYCHOTHERAPY IN EVERYDAY PRACTICE

EDWARD WEISS, M.D.

Philadelphia

I speak as a practitioner of medicine and not as a psychiatrist, and that is a different matter. When a patient comes to the psychiatrist he comes prepared to discuss his emotional problems, but when he consults a general physician he is almost always looking for a *physical cause for his trouble.*

But in at least one third of all the patients who consult a physician no definite bodily disease can be found to account for the illness, and in another one third of all patients the symptoms are not explained by, or are out of proportion to, any organic disease that can be discovered. In this group of patients are many in whom there seems to be a definite relationship between the emotional life and the physical disease; in other words, the emotional factor apparently plays an important part in causing the disorder. This is the group to which the term psychosomatic affection is often applied.[1]

While psychosomatic is a new term, it describes an approach to medicine as old as the art of healing itself. It is not a new specialty but rather a point of view which applies to all aspects of medicine and surgery. It connotes the simultaneous application of physiologic and psychologic technics in the study of illness. It does not mean to study the soma less; it only means to study the psyche more. It is not a new discovery, but rather a reaffirmation of the ancient principle that the mind and the body are interactive and interdependent, a principle that has always guided the intelligent general practitioner. Indeed, the traditional old family doctor often was an excellent psychosomatic physician, although he never thought of himself as such. He and his patients usually were intimate friends, and he was familiar with their social situation, as well as with their psychologic and physical peculiarities. He was well aware that these factors were related to illness. As a science, psychosomatic medicine aims at discovering the precise nature of the relationship between the emotional life and bodily illness.

Read before the Section on General Practice of Medicine at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

From the Department of Medicine, Temple University Medical School.

[1] The term psychosomatic as used in this paper indicates: (1) a method of approach to general medical problems—the simultaneous application of physiologic [illegible]s to the study of illness in an effort to make a [illegible] in preparation for comprehensive medical care; [illegible] sense, a disorder which can be understood only when psychologic as well as physiologic factors are taken into consideration (Halliday [2])

It is the special point of this paper that psychosomatic technics of diagnosis and treatment must become an integral part of the practice of medicine in order to fulfil their promise and meet the challenge of present day medical problems. The enormous number of psychoneurotic and psychosomatic problems turned up by the Selective Service process and encountered in military medicine indicates where the emphasis must be placed in the practice of medicine. World War I established psychiatry on a firm scientific basis and World War II has seen its more complete integration into general medicine, in other words, psychosomatic medicine. When that integration is accomplished there will be little need for the term psychosomatic; good medicine will be psychosomatic medicine.

PSYCHOSOMATIC DIAGNOSIS

When a person gets sick he is sick all over; that is, the body and mind are one, and he gets sick for a variety of reasons, physical and psychic. In other words, it is usually not one thing that determines illness; there are multiple factors acting together. In our approach to illness Halliday[2] stated that we must think: 1. What kind of a person are we dealing with (inherited and acquired characteristics, physical and psychologic)? 2. What has he met (germs, allergens or emotionally disturbing events)? 3. What has happened (the physiologic mechanism or pathogenesis of the disorder)? For example, allergic responses occur when a prepared organism, possessing certain physical and psychologic characteristics, meets certain elements, physiologic and psychologic. In some allergic disorders a single preponderant factor may be largely responsible, as for example in pollen hay fever. In others, such as asthma, there are frequently multiple interrelated factors, allergens and emotional disturbances, which act in a complementary fashion to produce the disorder.

Just as I insist on this unity regarding the nature of illness—the body and mind are one—so do I urge that the means of investigation are two—physical and psychologic—and their simultaneous application represents psychosomatic diagnosis. Moreover, they are applied simultaneously, although their application is often unconscious and unscientific. We physicians in our usual approach to the patient, using the orthodox methods of medical history, physical examination and laboratory studies, at the same time make many intuitive observations about the unconscious mental processes of the patient as exhibited in his language and behavior. What is here suggested is that order be brought into this intuitive process. We now have enough understanding so that we can begin to forge a scientific instrument in the exploration of unconscious mental processes (Kubie[3]). In other words, we are trying to make the rules regarding psychologic exploration as exact as the rules of physical investigation.

Rather than be satisfied with loose terminology—neurogenic factors, emotional upsets, physical and mental fatigue, emotional stress and strain—we must make an effort to define the specific emotional problem and relate it to the total personality makeup of the patient.

Just as we try to establish certain postulates for an allergic problem, hay fever for example, (1) heredity, (2) seasonal history, (3) skin tests, (4) antibodies, (5) induction of an attack with pollen and (6) hyposensitization or avoidance of offending substance in controlling attacks, so in the psychosomatic problem we try to establish (1) a family history (heredity and pseudoheredity) that suggests a background for psychologic difficulties; (2) evidences for a childhood neurosis; (3) sensitivity to specific emotional factors (temporal relationship of present illness and emotionally disturbing event), especially at epochal or crucial life periods (puberty, marriage, childbirth, climacteric, etc.); (4) a specific personality structure (other evidence of neurosis or character disturbance); (5) demonstration of specific behavior on taking the history (artificial exposure to a conflict situation); (6) hyposensitization by psychotherapy or the avoidance of the provocative situation.

We will not be able to establish all of these postulates in every case. For example, evidence for a childhood neurosis will often be missing—neither the patient nor his family can recall disturbed behavior or bodily dysfunction.

So far as allergy is concerned the fact that the removal of an allergen or a hyposensitization process "cures" the patient proves only that one factor has been removed and the morbid chain of events interrupted. Exactly the same reasoning can be applied to psychologic factors.

Heredity is often held responsible for illness that arises from the environment. This is an important consideration to which too little reference has been made. Children identify themselves with their parents and unconsciously imitate them, and thus patterns of behavior are laid down (which include illness as an aspect of behavior) so early in life that we often attribute a disorder to heredity when in fact it was acquired. This of course is an involved question, and I presume that the final answer can hardly be hoped for, that is, to separate constitutional and environmental factors with precision. But unconscious identification with a sick parent or other member of the household in early childhood often is the basis for an illness later in life which we may attribute wholly to heredity. When a young child is exposed to a sick parent it often shows the effect in psychosomatic illness in adult life.

Body Language.—Body language is a satisfactory explanation and approach to many medical problems. It has been suggested that the most satisfactory way to deal with tension is by action, the least satisfactory is by thought, and in between is speech. In other words, in all persons with psychosomatic illness there is some impairment of total functioning, and often a great deal of energy is consumed by thought (fantasies). If we can encourage them to get their thinking onto the surface by talking about their problems we can often understand the illness better and at the same time provide some measure of relief. Thus I often say to my patients that they are like engines with the steam up. If the wheels do not go around in productive work and the whistle is not blowing in talking about their troubles then the steam must try to get out somehow and it makes an effort to part their seams. It is a homely explanation which people readily grasp, as they realize that this short circuiting of energy is capable of disturbing their bodily functions. Therefore we can say to patients that if they cannot express their tension by word or action—if they cannot say with their mouths what is disturbing them—then one of their organs will try to say it for them. Thus, the patient with nausea, who has no evidence of organic disease, may be indicating that he cannot "stomach" certain situations; the patient with an itch often "lets things get under his skin." Many additional examples could be

given[4] to show that the patient often expresses his body language in symbolic formulas if we would only listen to him.

Another satisfactory way to get patients to discuss themselves in relation to their illness is to use a case illustration. Repeatedly this is effective when other methods of trying to make patients see the relationship between emotions and illness fail. If the physician can think of an apt case illustration the patient can readily identify himself, and even if there are pronounced divergences the patient will often see a partial application which will encourage him to talk about his personal life. Sometimes he will deny the application only to go on from that point to discuss emotional factors of importance which previously he was unable to think of.

History Taking.—An important element of the doctor-patient relationship enters into the taking of the history. I cannot discuss all of the qualifications of the physician who should interest himself in psychosomatic problems. Here it is only necessary to say that he must be so constituted that he can listen to the patient uncritically. Sympathy for patients suffering from illness of emotional origin is an essential part of the equipment of the physician who would interest himself in psychosomatic problems. If he is unsympathetic it will show in his manner and will discourage the patient from revealing feelings that are essential to an understanding of the problem.

In addition, a physician's ability to use the psychosomatic approach will depend on his knowledge of psychopathology and tissue pathology applied simultaneously. Therefore his human understanding, sensitivity and sympathetic appreciation of emotional factors as a cause of illness, as well as his orientation and experience, are all important in determining his ability to deal with psychosomatic problems.

Experience, of course, is important in history taking, but if one practices medicine for fifty years he will still have to give time to the patient. In other words, there are no short cuts in history taking—while the most experienced persons will quickly grasp the situation, time must be taken because the patient cannot be hurried.

The revered family doctor of the small community utilized his knowledge of his patients' personal lives in evaluating their history. He knew everything that was going on and had a background of understanding gained from personal observation. Now in our elaborate medical institutions, with a lack of knowledge of the patient's background, we overemphasize the so-called scientific aspects of medicine and relegate to the background the social and emotional factors that may enter into illness. As a consequence our methods of history taking have not kept pace with other methods of progress in medical science. Really our history forms and technics are indicative of one of the basic faults in medical knowledge and medical teaching.

The body is still divided into many organs and systems; specialists look on disease from their narrow point of view, and the curriculum is built up by introducing more and more special points of view. As a consequence the comprehensive point of view, which is so necessary to the study of illness as an aspect of behavior, makes little headway. The medical history form which we give to our medical students reflects this organic approach and this age of specialization, and we look in vain throughout a long history for some evidence of the human being who is sick. If patients were allowed to talk more and were examined less it would be a good thing for medicine in general. As one patient who had been through the mill of medical investigation recently remarked, she was suffering from "testitis." Indeed how numerous are the patients who have been examined again and again by means of the roentgen ray, chemical studies and various other expensive and complicated methods, accumulating a sheaf of papers, but with an end result hurtful rather than helpful because the diagnosis was obscured by concentration on a part rather than on the whole.

The majority of persons who consult a general physician wish to find some physical cause for their ailment, and thus fall readily into the system of answering specific questions about physical health and volunteering no information about themselves as persons. Moreover, people look on the physician as an authoritarian figure who will "do something" about their illness and are usually quite unprepared to have "to do something for themselves"—in other words discuss themselves as persons as well as "medical cases." We must look for the person in the patient. I have frequently observed that the patient who insists "that his illness is physical" is apt to be suffering from a disorder of emotional origin, while the patient who is eager to blame it on the psyche often has an organic disease. Many persons, seriously sick with advanced organic disease, seek to delude themselves with the idea that it may be "all mental." This applies especially to the many lay persons who have now read some of the popular writings on psychosomatic medicine.

The introduction of the psychosomatic point of view does not require a different form of history taking; it only requires an awareness of the role that the emotions play in illness and hence more emphasis on certain aspects of history taking. Thus the history need not differ in form but it must differ in substance. In accordance with what has been said more attention will be paid to the behavior of the patient and to the actual words that he uses in describing his complaints as well as the asides and apparent irrelevancies that so often give important clues to the emotional factor. Other fundamental considerations are to give the patient time, allowing him to talk with as few interruptions as possible. Avoid extensive notetaking, so that the patient may feel that you are more interested in him as a person than in the setting down of the history. Show interest and sympathy for what the patient sometimes regards as trivial or silly and pay close attention to the chronologic development of the life history, with special emphasis on the various factors in the childhood period that may have influenced the development of the personality. Special attention should be given to puberty and adolescence with their frequent emotional problems and to the epochs and crucial periods in life when psychosomatic disturbances are apt to arise. Inquire into the health of the spouse; neurotics have a way of attracting one another. Try particularly to obtain a more complete picture of the family background.

Chronologic Development of Life History.—There are two main approaches to the study of the patient with suspected psychosomatic disorder: a cross section study of his personality as he appears at the time of the interview and a longitudinal survey of his life from family background and early infancy to the present time. The first approach, the cross section point of view, is combined with the story of the present illness. It is the traditional approach of the physician to his patient, and the only requirement so far as the psychosomatic history is concerned is to develop the social and psychologic aspects in order to see if there is a relationship between the life situation and the medical illness.

---

[4] Weiss, E., and English, O. S.: Psychosomatic Medicine, Philadelphia, W. B. Saunders Company, 1943, p. 10.

The cross section approach tries to relate the present illness and the precipitating emotional factor. The longitudinal study relates personality development and the past medical history. It gives a better idea of the personality structure and psychopathology because it shows the background and the development of the personality. One technic does not exclude the other. On the contrary, the data derived are complementary and help to make up a definitive psychosomatic diagnosis.

Definitive Diagnosis.—Just as in a consideration of somatic disease it is necessary to make a complete diagnosis before we can hope to apply scientific treatment, so it is equally necessary in psychosomatic medicine. Hence, just as in general medical teaching, we have always emphasized etiologic, anatomic and functional diagnosis, so in psychologic medicine, as pointed out by Levine,[5] it is necessary to make a clinical, dynamic and genetic diagnosis before we can stand on safe ground in regard to psychotherapy.

The clinical diagnosis in psychosomatic medicine refers to the structural and physiologic deviations as well as to the underlying or associated psychologic disturbance. For example, in the so-called organ neurosis, we should like to know whether we are dealing with a mild personality disorder such as hysteria or a severe personality disorder such as hypochondriasis. It is important, in a functional gastrointestinal complaint, to know whether the symptoms are on the basis of conversion hysteria or a part of the clinical picture of depression in which the mood disturbance is overshadowed by the somatic complaints. When one deals with depression there is often the threat of suicide.

Dynamic diagnosis refers to the meaning and purpose of the symptoms or behavior in terms of the particular personality and its structure. When this is coupled with the genetic diagnosis, which is derived from the longitudinal survey of the individual life history, we are then in a position to plan comprehensive medical care.

PSYCHOTHERAPY

Patients do not have to be told, "You are now undergoing psychotherapy." What we must do can be done in the usual relationship between physician and patient. 1. After a medical history, which takes account of personal factors as well as "medical facts," we should make a complete physical examination and such laboratory tests as are necessary to exclude physical disease or to establish the precise nature of the organic problem and the amount of disability which it in itself is capable of causing. 2. When the patient has been assured that there is no physical disease or that disability is out of proportion to the disease, it is usually easy by examples of psychic causes for such physiologic disturbances as blushing, gooseflesh, palpitation and diarrhea to make the patient understand that a disturbance in his emotional life may be responsible for the symptoms. 3. Continue to look for the person in the patient. The more one can persuade such a patient to talk about "his other troubles" the sooner does one come to an understanding of the "present troubles." The greater the success in switching the conversation from symptoms to personal affairs, the sooner does one come into possession of the real problem disturbing the patient. Encourage him to talk about himself as a person rather than as a medical case.

Usually one or more of three special fears are uppermost in the minds of such patients. One of the most common is fear of cancer; cancerphobia. A great many patients think they have cancer, and indeed most women who consult physicians will have the idea at some time. They do not always express it; in fact, they rarely directly express their fear of cancer. They often disguise it by a complaint about a lump, a swelling or a curious sensation in the abdomen or breast, and when they are assured at the end of a complete physical examination that they are free from organic disease, they heave a sigh of relief and say, "Oh, I am so glad because I thought I might have a cancer." With all of the propaganda for the early detection of cancer these fears are exaggerated, and I presume it is the price that we must pay for instructing people about cancer. I am not, of course, advising against such instruction; it is only that we must realize that we add to the apprehension of many patients by our emphasis on the early detection of cancer.

Another common fear is of heart disease. When pain in the precordial region as well as rapid beating of the heart, breathlessness and fatigue occur, suspicion of heart disease often arises. If it is remembered that the pain of cardiac neurosis bears no definite relationship to effort, is frequently described as sticking, needle-like, or soreness, that often it is associated with inframammary tenderness and hyperalgesia, so that the pressure of the stethoscope sometimes elicits it, and that it may be accompanied by a sense of choking as well as sighing respirations, there will be no difficulty in the differential diagnosis, particularly when these symptoms are associated with the whole picture and life situation of the person with cardiac neurosis.

The problem is not an easy one because the patient is apt to insist, "But there must be something the matter." He cannot understand that so much distress can occur unless some vital organ is seriously affected. Moreover, if one does succeed in reassuring him for the time being, he may continue to hold the reservation, "But if this sort of thing continues surely something will happen"; in other words, "How long can my heart stand this?" Telling the patient to control himself is like trying to hold back steam under pressure—if it does not come out the spout it tries to blow the lid off the tea kettle. Really a person is quite as incapable of controlling his anxiety as he would be incapable of controlling his own acutely inflamed appendix. As long as the discussion is kept on the level of trying to persuade him that he does not have physical disease one gets no place because one cannot argue with an obsession. One must get at the mixed feelings, the conflict, that underlies the anxiety, and this can only be done by encouraging the patient to talk about his personal problems. This discussion will usually have to do with the family group. For example, in a patient whom I saw recently, a young married woman caring for a sick mother, the feelings of respect and devotion opposed to the inner resentment at the effort and cost and disruption of her own family life led to anxiety which could not be dealt with as long as the approach was on the level of reassurance regarding the absence of organic disease, telling the patient that she must control herself, and giving phenobarbital.

The inability to concentrate often gives rise to the fear of "losing the mind." Along with this fear frequently there are ideas of suicide. Both are distressing to the patient and usually are not volunteered. When the patient is assured that it is his feelings which are involved and not his "mind" and that the reason his "memory fails him" is because he is so preoccupied with

---

5. Levine, M.: Proceedings of the Brief Psychotherapy Council, Chicago, Institute of Psychoanalysis, October 1942.

concern over his problems, then he may confess his fear that he was "losing his mind" or his ideas of doing away with himself.

Once these ideas are brought to the surface and ventilated, and the patient receives sufficient reassurance, then often much improvement occurs. Indeed the intensity of the fear and the amount of reassurance necessary to abolish it serve as a crude index to the depth of the neurosis.

It is a good rule to listen rather than talk. Giving advice on highly charged emotional matters is dangerous. To paraphrase Lindemann,[6] "Clumsy psychotherapy is as dangerous to the social life as clumsy surgery is to the physical life."

Marriage and Parenthood as "Cures."—One more point should be emphasized: The gastrointestinal tract is, above all other systems, the pathway through which emotions are often expressed in behavior. Why this is so becomes apparent when one considers that the infant's first contact with the world is through the mouth so that the processes of feeding and feeling must relate themselves to one another. Therefore, on the love and security or anxiety and insecurity which become associated with the nursing process will depend many of the psychosomatic relationships of adult life, called forth by events which awaken old associations. Truly it can be said that bed and board are as indissolubly related in the life of the adult as are sucking and sensuality in the life of the infant.

People almost always blame their illnesses on "something they et." I say, "No, it's probably something you met." And so often it is true that the life situation has precipitated the trouble but instinctive tendencies place the blame on something swallowed; i.e., the food eaten at the time. In the same connection, people are gullible about wanting a cure by "swallowing" some magical medicine, vitamins, for example. I say to them, "The cure is not in swallowing; it's in spitting out"; in other words, talking about some of the things that are causing trouble.

It is not unusual for physicians to recommend pregnancy and parenthood as a cure for neurotic and psychosomatic illness. This prescription is rarely if ever of value. It is a rather safe rule that the unstable person will not be helped by becoming a parent, but will usually be made worse as a result of the added responsibility. How often on taking the history of neurotic persons, and especially women, does one hear, "I was perfectly well until my first child was born, but I haven't had a well day since." It is true that some neurotic women will feel better during pregnancy, but they pay dearly for their short period of improvement. Nor should the cost to the child be forgotten. Not only does parenthood not cure neurosis but it prepares the way for another spoiled life, because this is surely one of the ways in which neurosis is perpetuated. The atmosphere of the home in which there is serious emotional maladjustment creates the culture medium for the development of further emotional problems. This is the real "social disease." Psychologic contagion is as important as germs in causing illness. The advice to an incompatible couple—"What you need is a child; then you will have a common interest"—is as unenlightened as it is dangerous. While it may succeed in holding the marriage together, who can say how many children are thus sacrificed on the altar of incompatibility?

The Attack of Anxiety.—Rather frequently the first pronounced evidence of neurosis may be an attack of anxiety, and again and again in studying the histories of patients with chronic invalidism of emotional origin one finds that the first outspoken manifestation of illness was the sudden onset of anxiety with apprehension and dread. There are a feeling of weakness, sweating and a sensation that something terrible is about to happen. There are dyspnea, palpitation and, sometimes, nausea. The attacks usually last only a few minutes and subside rather quickly but may last for an hour or more. Weakness and fatigue follow. The emotional as well as the physical distress is so pronounced as to cause the patient to conclude that some serious physical disability is present. Almost never does he conclude that his difficulty is emotional. Most people prefer to think that physical distress means physical disease, and unfortunately physicians too frequently have assisted them in this belief. When a patient with an acute attack of anxiety is first examined, the physician notes the rapid pulse and listens to the pounding heart and all too often permits the patient to believe that the heart is diseased, that hyperthyroidism is present, or covers his unwillingness to make a diagnosis of a psychologic disorder by using some such term as neurocirculatory asthenia or autonomic imbalance. To give drugs and do nothing about fear is to mislead the patient into feeling that his distress is due to a physical disease rather than to an emotional disorder.

What is Psychotherapy?—What, indeed, is psychotherapy? Too often it is assumed to be something vaguely referred to as "the application of the art of medicine." This defies analysis but seems to represent a combination of the experience and common sense of the seasoned practitioner, an intuitive knowledge of people, the cultivation of a charming bedside manner, such trifles as serving food in attractive dishes and the generous use of sedatives, placebos and reassurance. The psychologic approach in medicine, essential for psychotherapy, consists of something more. It is a medical discipline to an equal degree with internal medicine itself. It is an effort to understand the personality structure of patients, the mental mechanisms which are at work and the specific relationships of psychologic situations in the precipitation of the illness.

Reassurance, in the majority of instances, unless combined with an analysis of the illness from the standpoint of the behavior, gives only temporary help and depending on the degree of anxiety, has to be repeated constantly, like a dose of digitalis in a failing heart. Closely allied to reassurance is another superficial treatment that rarely results in more than temporary help; i.e., environmental manipulation, without any attempt to give the patient insight into his conflicts.

Real psychotherapy, which is directly the opposite of simple reassurance, tries to make the patient understand the meaning of his symptoms and the nature of his conflicts. It is a process of reeducation and, when properly done, leads to sufficient emotional development so that the necessity for symptom formation is abolished. The best example of this kind of psychotherapy is psychoanalysis, but for various reasons this method cannot be applied directly to the majority of patients. Nevertheless, psychoanalytic insight and guidance prove adequate to handle the emotional factor in the majority of psychosomatic disturbances. Between simple reassurance at one end of the scale and adequate psychoanalysis at the other there are all degrees of psychotherapy which can be applied, depending on the degree of illness and circumstances of the patient.

---

[6] Lindemann, E.: Therapeutic Procedures in Psychoneurosis, New England J. Med. **227**: 584, 1942.

Major and Minor Psychotherapy.—A considerable number of these patients cannot be sent to psychiatrists, nor is it necessary. Not that there is anything reprehensible about consulting a psychiatrist—this too is a problem of education—but there are not enough psychiatrists to take care of the thousands of patients, and moreover, as I have tried to show, a great part of this work lies in the field of general medicine. Another way of stating the problem is to say that there are a major and a minor psychotherapy just as there are a major and a minor surgery. Many physicians who practice general medicine feel themselves capable of doing minor surgery, but only a few have the skill to attempt major surgery. They would not permit themselves to attempt something for which they are not prepared. This is just as true in regard to psychotherapy. The general physician must be able to treat the minor ailments, but he must be able also to recognize when the problem is beyond him, and then refer the patient elsewhere for major psychotherapy. Such knowledge and such an approach frequently will save the patient from unnecessary troublesome and expensive medical or surgical treatment with a resulting further degree of invalidism.

Cost of Psychotherapy.—What about the question of time, effort and expense of psychotherapy? True it is that all of this takes time and effort and must be paid for; yet when one looks into the time, effort, and expense that have been expended by many patients or by institutions taking care of these patients in the usual medical approach, one realizes that an hour or two well spent in a discussion of the life situation of such patients would obviate a great deal of this expense. It is amazing what the total expense of a great many of these unnecessary studies amounts to so far as the institution is concerned, and of course the same thing is true in the case of private patients. The day is close at hand when we will regard some of these "thick chart" patients, this polyphysical approach, with the same amusement and disdain with which we now regard the polypharmacy of a bygone age in medicine. Hospitals are beginning to understand that it is not only intelligent but economical to utilize the service of a psychiatrist in the general medical division, and this same idea can of course be applied to private patients, with this difference, that the majority of them can be and should be handled by the general practitioner. But he asks, "How can I possibly take the time to do this and, if I do, how can I make a living?" I answer that it is not necessary, of course, to make such a detailed inquiry in every patient that one sees, but, in chronic illness in particular, when one feels the necessity for such a study, then time must be taken and in the end will prove economical not only from the human standpoint but from the standpoint of cost of medical treatment. If one cannot take the time in the midst of a busy office hour for a special patient then an appointment can be made for the purpose. It will be worth while as far as the health of the patient is concerned and in satisfaction to the physician.

SUMMARY

The main point of this discussion can be stated briefly: The study and treatment of illness constitutes much more than the investigation and eradication of disease. Yet there is nothing new or startling in this point of view. We have heard a great deal in recent years about the study of the organism as a whole, but for most part we have been paying only lip service to this concept. We have been led to believe that the art of the physician, having to do with his common sense or intuition, as opposed to his science, is sufficient to grasp the problems that we have been considering. It is not enough. A real understanding of psychodynamics is necessary in order to study the emotional life in relation to ill health.

It is my hope that every physician will be so trained that he may be able to understand and manage the many emotional problems that are presented to him daily. At the postgraduate level we need short orientation courses in centers that are properly staffed. At the graduate level better training facilities should be developed for residents in medicine, and the other medical specialities, to acquire the psychosomatic approach to medical problems. At the undergraduate level, we need, not more and more hours of psychiatry inserted into the curriculum, but a real integration of the psychosomatic point of view in every department, preclinical as well as clinical. As Margolin[7] has well said, we need homogenization instead of stratification. This of course must wait until teachers are available in these various departments who have a real understanding of psychodynamics. And beyond this, or rather before this, our students must come to us prepared in the social sciences as well as in the physical sciences. And the social sciences must include a psychology that gives a better explanation of human behavior than is now furnished in most colleges. All of this, unfortunately, is a long way off, and yet we are moving swiftly. Military medicine gave a great impetus to this development and the pressure is going to come from the people themselves. We would be wise to anticipate them. Therein lies our hope for an important development in medicine. As a part of this process and essential for its development general hospitals must establish divisions for the observation and treatment of psychoneurotic and psychosomatic problems. The time has passed for psychiatry to lead an isolated existence. Until it is brought into physical proximity with general medicine it cannot achieve final integration into the body of medical knowledge.

ABSTRACT OF DISCUSSION

Dr. O. Spurgeon English, Philadelphia: Patients like familiar terms when the cause of their illness is diagnosed. They feel at home with words like ulcer and bronchitis, as they have some experience already with these conditions. They feel less sophisticated about anxiety and the symptoms it will produce such as weakness, dyspnea, palpitation, nausea or dizziness. In this field it is well to be armed with what Dr. Weiss has called the "homely explanation for symptoms." To understand the attack of anxiety and its results, then, it is necessary to recall to patients the familiar phenomena of early childhood, such as a fright by a dog, being lost in a store or growing panicky in a fast moving elevator. The mother soon cures the anxiety and accompanying symptoms of breathlessness, palpitation and body discomfort in such cases. When the patient knows that anxiety is a familiar nonlethal phenomenon frequently present during growth and knows that he may cease worrying about illness in his body and start creating and acknowledging the kind of friendship, kindness and good will which cure childhood anxiety, then and only then does he get the right therapeutic attitude and begin to make progress. It is not easy educational work, but if mastered it is most important for the patient's welfare. It cures many, prevents others from chronic invalidism, and, finally, if some have to be referred for specialist treatment, it has started the treatment on a sound basis consistent with the philosophy of psychotherapy generally.

Dr. Sidney A. Portis, Chicago: It is difficult for those trained in the organic school of medicine to evaluate end results.

---

[7] Margolin, S. G.: Personal communication to the author.

There is still a paucity of accurate measurements in this field. However, I think it is important to recognize there is no such thing as a neurotic patient. The patient's illness is interdependent on a disturbed physiologic balance in the body which is the result of altered stimulation of the nervous system originating in the higher emotional centers. We can no longer dismiss the complaints of these patients because we cannot find any organic evidence to substantiate the symptom complex. This is especially true in gastroenterology. If the average gastroenterologist cannot find organic evidence of disease to correlate with the clinical picture of the patient, he frequently gives the patient the "brush-off." I often wonder why this presumed hostility has developed in physicians and conclude it is because they do not have sufficient insight into the effect of emotional stimuli on body processes. The average gastroenterologist could honestly say that between 70 and 80 per cent of his office patients fall into a group in which there are no organic findings either from the laboratory or the roentgenologic point of view that can be correlated with the clinical picture. This important problem confronts all of us daily. An important factor in handling this type of patient is to gain his confidence. The patient should be told that he has no organic abnormalities at present but continued altered physiology may lead to subsequent organic changes. Peptic ulcer and ulcerative colitis may classically fall into this pattern. The patient must be impressed with the fact that the normalization of this so-called pathologic physiology will result in the relief of his symptoms. We must approach the patient's problem with a great deal of sympathy, tolerance and understanding. We must give him insight into the factors which led to the development of his disability. One can usually discuss early childhood patterns, life situations and environment and bring home to the patient that this disturbed emotional household has led to the development of the present symptom complex. I continually try to teach my interns, residents and associates in the office that they should be sympathetic to the life situations of the patient. At the outset it may be difficult for some physicians to gain the confidence of their patients when facing these problems because the patient soon learns that the doctor is not sure of his ground. However, as experience increases and sincerity develops, the problem becomes easier and the patient will develop a transference to his physician just as he does to his psychiatrist. Finally, it is important for the physician to recognize that a sympathetic history should be taken for the patients who have emotional complaints. The patient should at no time be aware that this point of view is uppermost in the mind of his physician. He then should be given the benefit of a thorough laboratory and roentgen investigation. With all these facts before him, the physician is in a much better position to advise the patient about his problem and the task will be much easier.

Dr. Herbert F. Robb, Belleville, Mich.: There are definite psychic factors in functional and organic disease which are too often overlooked and ignored; nevertheless we should not fail in our treatment of the patient to give proper consideration to biologic and social factors which have to do with psychic reactions which in turn are associated with functional and organic diseases. In our revolution of environment from a rural agricultural to an urban industrial civilization there have been great changes to which we have not adjusted ourselves, one of which is our diet. In 1840, 55 per cent of the calories in the American diet were in unprocessed cereals, and according to Moore's "Pathology" there were 600 international units of vitamin B_1 in the average daily diet. Today, about 45 per cent of the calories are in cane sugar and processed cereals which contain about 50 international units of vitamin B_1. B_1 avitaminosis causes a disturbance of metabolism of carbohydrates and the accumulation of intermediary products, lactic and pyruvic acids in toxic amount. There may result functional and later degenerative changes in the central and peripheral nervous systems and general nutritional changes due to interference with the gastrointestinal function. Experimental thiamine deficiency in man causes fatigue, lassitude, anoxia, bradycardia, precordial pain, with electrocardiographic changes and changes in the personality of the subject. He is sensative and can not take criticism without showing considerable emotion. B_1 and other avitaminoses affect a person, especially at the age of puberty during the age of rapid physical growth. School children often make good records until the sixth or seventh grades and then begin to fail because of mental inadequacy as the result of thiamine deficiency. In three or four years they are so far behind their age group that they frequently become delinquent, start skipping school and are sent to the detention home for wayward children. Dr. Weiss mentioned that many women date their illness from the birth of their first child. Frequently psychical and functional disturbances are associated with the use of unsatisfactory contraceptive practices. This problem is much worse in our industrial urban civilization with its later marriages and lower birth rate than in the rural agricultural community with younger marriages and higher birth rates. Biologic and sociologic factors should not be overlooked in the use of psychotherapy.

DR. EDWARD WEISS, Philadelphia: I would suggest in closing that we listen rather than talk to our patients and that we try not to give advice on involved emotional matters, such as marriage and divorce. Then comes the question of missing organic disease. Somebody usually reminds me that in becoming interested in psychosomatic medicine one may overlook organic disease, not mentioning that an exclusive organic orientation leads to equally serious consequences in overlooking neurotic illness. Of course, as long as we are human, we are going to make mistakes. But if we plant one foot firmly in tissue pathology and the other foot firmly in psychopathology, then I think we have the correct balance for this approach.

ABNORMAL PRESENTATION

H. HUDNALL WARE JR., M. D.
Richmond, Va.

The subject abnormal presentation necessitates a discussion of several abnormalities. In the limited time for this paper I will review only the salient points of each.

First, one should remember that every pregnant woman is entitled to a careful complete physical examination and accurate pelvic measurements early in pregnancy regardless of whether she is a private or a clinic patient. A careful pelvic examination may reveal abnormalities of the bony pelvis or soft tissues which often predispose to faulty presentation when the pregnancy is at term.

Routine examination of the patient's abdomen and the use of Leopold's four maneuvers during the last month or six weeks of pregnancy will enable any physician who is a careful observer to diagnose the position of the fetus before the onset of labor in most cases. When an abnormality is suspected, a roentgen examination of the mother's pelvis and the fetus is certainly indicated. Fetal abnormalities, as well as maternal abnormalities, predispose to abnormal positions. A fluoroscopic or roentgen examination may prevent an unnecessary operation done primarily in the interest of the baby.

Hydrocephalus can be diagnosed by roentgen examination, but some abnormalities of the soft tissues of the fetus may not be recog-

---

Read in a panel discussion on Problems of Delivery before the Section on Obstetrics and Gynecology at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N.J., June 11, 1947.

nized until the labor is delayed and intrauterine examination is resorted to. I have seen 2 cases in which a large meningocele had to be perforated before the after-coming head in a breech case could be delivered. Enlargement of the fetal abdomen may be due to ascites, cysts of the kidneys, a distended bladder, enlargement of the liver and other organs.

Titus[1] said, "when there is hydramnion, the excessive fluid interferes with engagement, while in multiparas with relaxed abdominal walls this favors displacement of the presenting part." Falls[2] has called attention to abnormalities in the shape of the uterus as a cause of abnormal presentations.

Oblique presentation is usually transitory, and converts into either a longitudinal or a transverse presentation early in labor if not before. Whenever recognized in the latter months of pregnancy or early in labor, an attempt should be made by abdominal manipulation to change the oblique to a vertex presentation. When this procedure is attempted in the latter months of pregnancy the patient should then wear a form-fitted maternity corset or abdominal binder Pads may be used to keep the head over the pelvic inlet.

Transverse presentation occurs when the long axis of the fetus crosses the long axis of the mother at about a right angle. Torpin[3] reported the incidence of transverse presentation as 1 in 615 in Negro women and 1 in 1,090 in white women. Titus,[1] Greenhill[4] and others stated that shoulder presentations occur about once in 200 cases, and more often in multiparas than in primparas. Stander[5] stated, "The existence of a transverse presentation in a primiparous woman is a prima facie evidence of a lack of accommodation, usually the result of disproportion between the size of the head and the pelvis, though occasionally it may be due to hydramnios." In multiparas, the most frequent etiologic factor is abnormal relaxation of the abdominal and uterine walls. Falls has shown that abnormalities in the shape and size of the uterus predispose to transverse presentation.

All authorities have agreed that transverse presentations are dangerous for both the mother and the baby. Prolapse of the umbilical cord is a frequent complication when the cervix is partially dilated and the membranes have ruptured. Labor is frequently prolonged and delivery difficult, resulting in a high fetal mortality. Maternal exhaustion, a tight uterus and finally rupture of the uterus occur frequently in the neglected cases of transverse presentation. This danger can be reduced by careful examination of obstetric patients late in pregnancy and early in labor. The pelvic measurements should be reviewed, cephalopelvic disproportion must be carefully looked for, and other abnormalities ruled out.

If the transverse presentation cannot be converted to a vertex, and there is some degree of pelvic contraction, cesarean section should be elected. This applies to patients who have not been contaminated by internal examination and those whose membranes have not ruptured. If the patient is seen after rupture of the membranes or the onset of labor, and she has a disproportion, but has not been contaminated by internal examination, membranes have been ruptured only two or three hours or she has been in labor six or eight hours and the fetus is still in good condition, she may be delivered by low cervical flap or extraperitoneal cesarean section.

When there is no disproportion, and the patient is in labor with some dilatation of the cervix and the membranes have ruptured but the uterus is not tight, a Braxton Hicks version, pulling down one or both feet, may shorten labor and reduce the danger of rupture of the uterus. Unfortunately, this procedure carries a high fetal mortality.

If the pelvis is normal, the baby not too large and the uterus well relaxed, a large Voorhees bag may be introduced with the hope of preventing prolapse of the cord and obtaining dilatation of the cervix. The delivery of the baby may then be completed by internal version and breech extraction. In my experience, this procedure has proved both dangerous and of limited value.

When a transverse presentation has been neglected, the uterus has become tight, the fetus is dead or in poor condition and the maternal pelvis is ample, decapitation of the fetus and extraction of the body, and then the head, may be the operation of choice. When the aforementioned conditions exist and there is real pelvic contraction, it may be necessary to do a cesarean section and hysterectomy. I think that rupture of the uterus is a real danger when a transverse presentation is present and neglected. Destructive operations on the fetus cannot be done without some danger to the mother.

Brow presentations are said to occur once in 1,500 cases. These presentations are usually transitory but frequently result in face presentations because of further deflexion. The treatment of a brow is intelligent expectancy unless there is disproportion between the fetal head and the maternal pelvis. When the latter condition exists, the baby should be delivered by cesarean section while it is in good condition and before the mother has become contaminated or exhausted.

Face presentation occurs once in 200 to 500 cases. The face presents when deflexion is carried to its highest degree. Fortunately, the majority of face presentations terminate

spontaneously and without assistance. Again I emphasize a review of the pelvic measurements and a careful estimate of the fetal size, particularly the fetal head, to determine the cause of the presentation. If there is a true disproportion, the fetus should be delivered by elective cesarean section before the onset or early in labor.

When the chin is posterior with a face presentation, spontaneous delivery is impossible unless the fetus is small and the pelvis large. In a normal pelvis an attempt should be made to rotate the chin forward or change the position. If this fails and the uterus relaxes, the fetus may be delivered by internal podalic version and breech extraction after the cervix is fully dilated. If this is impossible and the baby and the mother are in good condition, delivery may be accomplished by cesarean section.

Breech presentation occurs in about 3 per cent of all deliveries. It is considered as abnormal because of the high fetal mortality resulting from it. The maternal mortality is not usually increased by breech presentation, but maternal morbidity is increased, and injuries to the maternal soft tissues do frequently occur in breech delivery.

The fetal mortality rate in breech presentation can be reduced and traumatic injuries resulting from breech delivery are usually preventable.

As in any obstetric case, accurate pelvimetry before the onset of labor and consideration of the attitude and size of the fetus will give valuable information to the obstetrician. When the baby presents as a breech in a patient with a borderline or slightly contracted pelvis, roentgen examination of the baby and the mother's pelvis will give information which is useful at the time of delivery. In a recent review of 236 consecutive breech deliveries, there was uncorrected stillbirth and newborn death rate of 5.46 per cent. When correction was made for babies with congenital deformities incompatible with life and babies who died in utero before the onset of labor, the combined mortality rate for both stillbirths and newborn deaths was 2.7 per cent.

I believe that the onset of labor should be spontaneous in cases of breech presentation whenever possible. The membranes should not be ruptured until the cervix is fully dilated. The fetal heart rate should be watched closely. Delivery should be with the mother under anesthesia, and body, shoulders and head of the baby should be guided through the pelvis even when the hips deliver spontaneously.

Delivery of the breech through the vagina should not be attempted until the cervix is fully dilated and retracted. In the presence of a normal pelvis, the second stage should not be permitted to be unduly prolonged before extraction of the baby. A wide episiotomy before delivery of a breech presentation reduces trauma to the baby and mother and decreases fetal mortality.

In assisting a breech delivery and whenever it is necessary to extract a baby presenting as a breech, I follow Potter's technic. Piper forceps are applied whenever the head cannot be delivered easily. The Celsus-Wiegand-Martin maneuver can be used to advantage in delivering the after-coming head through the pelvic canal whenever assistance is indicated.

When the fetus presents as a breech in a definitely contracted pelvis and there is cephalopelvic disproportion, an elective cesarean section should be done before the onset of labor.

DISAPPEARANCE OF CARCINOMATOUS ULCERATION OF BLADDER FOLLOWING URETEROSIGMOIDOSTOMY

Report of Two Cases

EDWIN DAVIS, M. D.
Omaha

It is my purpose to report the clinical disappearance of carcinomatous ulceration of the bladder following diversion of the urinary stream and to point out the possible biologic significance of this phenomenon in connection with the cause of certain tumors of the bladder. These observations are based on repeated cystoscopic studies confirmed by preoperative biopsy and by subsequent gross and microscopic examination of the excised bladder by competent pathologists.[1]

The obvious inference that these tumors were caused by a carcinogenic urinary ingredient is thought provoking and involves a consideration of the closely related subject of chemical carcinogenesis, which may be defined as "the production of malignant, transplantable, metastasizing new growths in laboratory animals or human beings by the action of cancer-producing chemicals introduced into the body, intentionally or inadvertently, by ingestion, inhalation, injection or cutaneous application" (Davis[2]).

Although having received but scant mention in other than special journals, the experimental achievements in this field during the past fifteen years have been little short of astounding. "Cancer may be produced at will in a majority of the animals treated, with a variety of chemical compounds" (Cook[3]), mostly prepared synthetically and of known molecular structure. Proved carcinogenic substances are exceedingly numerous and varied as to chemical structure and may be naturally occurring or synthetic, organic or inorganic and exogenous or endogenous in origin. There is evidence that carcinogens may masquerade unrecognized as *innocent substances*, resulting in chronic occupational, environmental, therapeutic or cosmetic contact. There is proof of the carcinogenic potency of certain *artificial ingredients of foodstuffs* (Cook and Kenna-

way[4] and Reding[5]), and evidence has even been submitted directing suspicion against certain foodstuffs themselves, including glucose, sesame oil (Schiller[6]), wheat germ oil (Rowntree and others[7] and Rider[8]), olive oil and lard (Burrows and others[9]). Steinor and his associates,[10] after an extensive investigation as to "the possible carcinogenicity of over-cooked meats" and other substances, advised "further study of the carcinogenic potency of heated vegetable fats." Awaiting confirmation is the report (Widmark[11]) of carcinogenic substances obtained from roasted meat and browned butter. Eller and Wolff,[12] reviewing the literature, concluded that "the evidence that experimental tumors can be produced by a diet rich in vitamins is inconclusive," although they stated that the majority of authors consider vitamin excess to be a factor in tumor initiation and tumor growth.

In addition to these multiple exogenous sources, carcinogenic properties have also been ascribed to certain endogenous (physiologic) substances produced within the body, acetylcholine and estrogens being among these. For instance, Hall and Franks[13] reported "an inordinate number of tumors which developed in various animals" during prolonged administration of acetylcholine. Cramer[14] considered the carcinogenic potency of estrogenic substances in the production of mammary cancer in mice, discovered by Lacassagne[15] to be "based upon evidence which is incontrovertible." Eller and Wolff, reporting a certain commercial estradiol-containing face cream which "produced cancer in animals, as well as other profound systemic changes, when applied on the skin in one-fifth the amount recommended for daily use by women," have quoted numerous warnings from authoritative sources against indiscriminate, prolonged use of estrogen-containing ointments. The chemical grouping known as the phenanthrene nucleus, possessed in common by the most potent of the carcinogenic hydrocarbons, is "widely distributed in nature in a variety of physiologically important compounds, including cholesterol, vitamin D, the bile acids and the sex hormones" (White[16]). Auchincloss and Haagensen[17] have commented on the unrestricted and promiscuous use of estrogenic substances in cosmetics. Moreover, this topic has been considered of sufficient importance to have appeared in the editorial columns of THE JOURNAL,[18] in which a distinct note of warning has been sounded. Supporting the work of Steiner,[19] who demonstrated the sporadic occurrence of carcinogenic substances in human liver (20 per cent of specimens examined), Hieger[20] has recently reported "a sarcoma-producing fraction—obtained from mixed lung-kidney-muscle of cancerous and non-cancerous human (autopsy) subjects."

This array of seemingly irrelevant and unrelated facts, indicating the multiplicity, variety and ubiquity of carcinogenic substances, is submitted by way of evidence that the idea of a carcinogen as an ingredient of human urine, either exogenous or endogenous in origin, is by no means fantastic and has in fact ample precedent. The so-called aniline bladder tumor of workers in dye factories which has been long recognized and whose identity and cause has been established beyond question, serves as a classic example of a new growth due to a carcinogen of exogenous origin inadvertently assimilated in infinitesimal daily dosage, through a long period of years by ingestion, inhalation or inunction. The brilliant achievement of Hueper[21] and his co-workers, who succeeded in the production of bladder tumors in dogs by feeding beta-naphthylamine (one of the "intermediates" in the synthesis of aniline dyes), has afforded incontrovertible experimental proof substantiating the mass of clinical evidence concerning the cause of these tumors. The amazing feature is that "aniline tumors" should be produced in an organ remotely removed from the point of contact with the carcinogen and nowhere in the body except in the urinary tract. Concerning the two schools of thought as to whether the contact of the carcinogen (or its "organic conversion products") with the epithelium of the bladder is via the urine or via the blood stream, Hueper[22] has cited evidence to show that "the majority of investigators" believe that the urogenous route is implicated. This opinion is in keeping with the known characteristics of tumors of the bladder and with the evidence herein presented.

The strange "habits" of tumors of the bladder, characterized by a strong tendency to multiplicity and to repeated reappearance (as distinguished from recurrence) elsewhere in the bladder following transurethral destruction, are familiar to all. It was reflection on this unconventional behavior of bladder papillomas, as well as on the extraordinary and intriguing facts in connection with "aniline bladder tumors" suggesting a urine-borne carcinogen, which stimulated my interest in chemical carcinogenesis. As long ago as 1942 I presented before the American Urological Association[2] a review of achievements in this field together with evidence justifying the hypothesis that the genesis of certain "spontaneous" tumors of the bladder might bear a relationship to unrecognized carcinogens masquerading as innocent substances and encountered through environmental or occupational contact or included among the endless list of drugs, remedies, cosmetic concoctions, synthetic vitamins and sex hormones and

the countless aniline dyes used in the coloring of foodstuffs and fabrics.

In the discussion following the presentation of this paper Dr. Robin Pearse,[23] of Toronto, Canada, at my insistent request, reported "two cases of marked regression of infiltrating papillary carcinoma of the bladder occurring after the bladder had been at rest." Although it is not clear whether it was his purpose to emphasize the resting bladder or the absence of urine as the causative factor and although preoperative confirmation at biopsy was lacking, the evidence submitted by Dr. Pearse of the relationship between ureterosigmoidostomy and "regression" of the tumor is to be viewed as impressive.

It was a consideration of these pertinent and intriguing facts which prompted speculation as to what might have occurred as the result of diversion of the urinary stream and which led to cystoscopic examination in the first case after a fifty day interval from the time of ureterosigmoidostomy.

REPORT OF CASES

My own observations on two "phantom" tumors were so essentially similar as to render separate detailed reports unnecessary. The patients were both men, aged 56 and 60 respectively, and each complained of hematuria without other symptoms or physical symptoms of significance. In neither case could the tumor be made out by combined rectal and abdominal palpation under spinal anesthesia.

Preoperative cystoscopic examination in the first case showed a rounded, crater-like ulceration, about 2 cm. in diameter and with an elevated edge, situated just behind the trigone and to the left of the midline. In the second case it was not possible to distinguish positively by cystoscopic inspection alone between inflammation and new growth. This lesion, situated on the left lateral wall of the bladder and being 2½ cm. in diameter and slightly elevated, showed an edematous-looking, reddened surface but no actual ulceration and no papillary processes. The rest of the bladder was normal in each case.

Preoperative biopsy specimens, removed with the resectoscope, in each instance were reported as showing the presence of carcinoma. In the second case Dr. Tollman and Dr. Eggers concurred in the opinion that the histologic picture was that of a highly malignant type of carcinoma.

Bilateral ureterosigmoidostomy in each instance was uneventful with respect to both technic and convalescence.

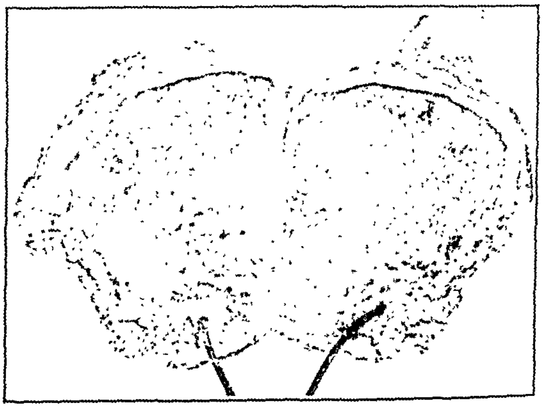
Postoperative cystoscopic inspection, carried out by my associate, Lr. Lee, and myself with caudal anesthesia, with excellent illumination and with excellent cooperation on the part of the patient, showed the bladder mucosa to be perfectly normal throughout after postoperative intervals of fifty and seventy-one days respectively. There was no indication that these were the same bladders previously visualized.

Postoperative biopsy, performed in 1 case only, showed cancer cells situated in the underlying muscle tissue of a deep bite of normal mucosa removed at the site of the previous ulceration with the resectoscope loop.

Cystectomy, performed with the patient under continuous spinal anesthesia, in each instance was uneventful as was convalescence.

The pathologic reports likewise were strikingly similar. In each case careful gross inspection of the excised bladder showed no evidence of intravesical new growth or extravesical extension. However, microscopic section of the wall of the bladder showed cancer cells in the tissues underlying the normal mucosa in each case.

In case 1, as reported by Dr. Tollman, "section of the wall of the bladder showed massive invasion by tumor, which in most places appeared as large unorganized masses of cells, with small areas at intervals showing distinct glandular formation." The diagnosis was adenocarcinoma of the bladder.



Sagittal section of specimen removed at cystectomy (case 2).

In case 2 " sections were taken at several points including the full thickness of the bladder wall. One of these sections showed residual tumor cells similar to those in the earlier biopsy specimen. " The diagnosis was papillary carcinoma of the bladder.

In response to follow-up inquiry each patient reported himself symptom free at the end of three and fourteen postoperative months respectively.

COMMENT

It is to be clearly understood that it is not my purpose to advocate ureterosigmoidostomy as a therapeutic or curative measure but rather to direct attention to the possible biologic significance of this phenomenon. It is true, however, that in cases in which the bladder tumor is not amenable to recognized methods of treatment diversion of the urinary stream may provide a gratifying degree of symptomatic relief and, incidentally, an opportunity for observation and for accumulation of data, and to this end cystoscopic examination after ureterosigmoidostomy is urged.

Since ample experimental and clinical evidence has been cited to provide precedent for the presence of a carcinogen (exogenous or endogenous in origin) as an ingredient of human urine, it is to be hoped that interest stimulated by these observations may further the knowledge concerning the origin of certain tumors of the bladder. The fact that cancer cells were shown to persist in the deeper tissues does not detract from the biologic significance of the complete disappearance of the intravesical portion of the tumors. In the event that the inference concerning a urine-borne carcinogen is correct, the possibility of confirmation by the development of tumors of the rectosigmoid after ureterosigmoidostomy is to be anticipated.

---

[23] Pearse, R., in discussion on Davis.[2]

ABSTRACT OF DISCUSSION

Dr. William P. Herbst, Washington, D. C.: Recently it has been our opportunity to observe the influence of a chemical substance on hopeless malignant growths of the urinary tract. We have used inositol, which is one of the members of the B complex group, and up to the present we feel slightly encouraged by the responses on the part of the bladder tumors. We used it on extensive growths and in inoperable cases. We felt that there was a definite improvement in the clinical course of the 4 or 5 patients on whom it was used, and several of them were able to leave the hospital and come back into the outpatient department for periodic observation. It is worthwhile to give testosterone to a patient who is to have a suprapubic operation preliminary to prostatectomy. You all have patients who do not see how they are going to submit to a prostatectomy, and frequently 25 mg. of testosterone will make that patient want to go ahead with the operation. We now have recognized psychogenic amenorrhea. We know from the British, who have done prefrontal lobotomy, that the ketosteroid level in the patients is zero before prefrontal lobotomy and that after prefrontal lobotomy, it becomes normal and the patients resume a more normal general physical activity. When we delve into this subject of chemistry as related to malignant processes, we should think of the psychic status of the patient and its chemical relationship, and we should strive to find more substances which will be on the other side of the list, which Dr. Davis has so excellently presented to us.

Dr. Armando Trabucco, Buenos Aires, Argentina: I should like to add another case to Dr. Davis' report. I performed an anastomosis of the intestine and when I took out the bladder I found no tumor present. A biopsy report six months previously had reported evidence of a papillary carcinoma of the bladder, situated on the right lateral wall and surrounding the bladder neck, but I found that both the bladder and the wall were free of tumor.

THE TREATMENT OF ASTHMA

A Panel Discussion

J. HARVEY BLACK, M.D., Moderator
Dallas, Texas

STATUS LYMPHATICUS

Dr. George Piness, Los Angeles: Status asthmaticus or intractable asthma is an asthmatic condition that does not respond to the ordinary methods of treatment. The etiology is limited: (1) home medication, (2) overmedication and (3) lack of fluids and food. The first and most important therapy is the amount of fluids that patients should receive. Patients can take fluids by mouth, but it does not seem to answer the purpose; they should be given as much fluid as they will take by mouth. The use of fluids intravenously or subcutaneously is more effective. I doubt that any of us realize the amount of dehydration that occurs in the asthmatic person who has been in attack for several days or weeks. The large amounts that I advocate are based on the evidence of having measured and observed patients who have had this condition and the amount that they could take. The average patient requires initially from 3,000 to 5,000 cc. per twenty-four hour period. I usually use distilled water with 5 per cent dextrose. Dr. Unger believes that aminophylline is satisfactory in continuous intravenous therapy in these asthmatic patients. My experience has taught me that it has no value. Aminophylline, in my opinion, is one of the most disappointing drugs in the treatment of status asthmaticus. Usually, if and when it does give relief, it is for a short period, is spectacular and does not last. The patients require mental and physical rest, the type of physical rest that can be best obtained by the avoidance of narcotics such as meperidine hydrochloride ("demerol hydrochloride" N.N.R.) opium tincture and morphine. The best sedative available is chloral. It is the only one I know of that has no effect on respiration. It does not depress. A small dose of phenobarbital is not objectionable. I have never found it to give any trouble in small doses. I do not believe it advisable in large doses. Potassium iodide is still the best drug that we have in addition to fluids. Without the addition of fluids, it has little value except to upset the patient. Iodides, given by mouth if possible and, if that is impossible, given intravenously, may be prescribed in sufficient dosage to assist in liquifying the secretions that these patients have and are unable to eliminate. Without fluids, it is impossible to thin out these secretions. Epinephrine has lost its value at that stage, but if it is continued over a period of time it can be used with effectiveness once again. I have found that when epinephrine is discontinued, caffeine acts as a satisfactory drug in that it is a pulmonary stimulant, perhaps extremely mild, but it does do something to stimulate the patient. In addition, hygienic and dietary care are necessary. If possible and if the etiology is known, it should also be attended to.

PENICILLIN AEROSOL SPRAYS

Question: What is your opinion of penicillin aerosol sprays? Is there a simple method of administering them without the use of expensive equipment?

Dr. Piness: My experience with penicillin sprays is limited. I have seen patients who had penicillin reactions resulting from penicillin sprays. I have never seen a patient who had any permanent measure of relief from it, but I have seen the sad and extensive reactions that have occurred from it. I can see few indications for penicillin in bronchial asthma, with the exception of secondary infections with bronchiectasis or perhaps small pulmonary abscesses. I cannot see any advantage in the use of penicillin by spray or otherwise in bronchial asthma without the secondary infections.

DUST EXTRACTS

Question: Please discuss the use of high dilutions in the treatment with dust extracts.

Dr. Piness: I am one of the few who do not believe in dust stock antigen. In most cases we can still determine the specific thing in the environment to which the patient is sensitive and perhaps are able to remove that offending substance or, if necessary, treat with the specific antigen to which the patient is sensitive.

OXYGEN

Question (Dr. J. Harvey Black, Dallas, Texas): Do you ever use oxygen at all with your asthmatic patients?

Dr. Piness: I do not use oxygen. I do not believe that the patient who has asthma, unless he has cyanosis, requires oxygen. Most patients have difficulty getting rid of their air instead of getting it. Rarely does one see an asthmatic patient gray and cyanotic with shock, unless it is an acute shock resulting from therapy or contact with specific antigen. I see no reason to use either oxygen or helium in status asthmaticus or in any other type of bronchial asthma.

ASPIRATION

Dr. Louis Tuft, Philadelphia: I want to make an additional suggestion. In patients with status asthmaticus who do not respond to the usual measures, my associates and I have found bronchoscopic aspiration to be a valuable adjunct in hospital treatment. It is well worth while considering when other measures fail.

DR. PINESS: In my experiences it is a rare occassion when the bronchoscopist can pull out that cast in the bronchus that results from the patient's being dehyrdrated and in status asthmaticus.

Dr. Charles H. Eyermann, St. Louis: Carrying on Dr. Tuft's idea, I have thought that some persons with status asthmaticus did better by mere tracheal aspiration, without the trouble of bronchoscopic aspiration. The treatment of patients with status asthmaticus should be on a physiologic basis, and each clinician has his own methods to attain these; namely, hydration, sedation and bronchodilatation.

PSYCHOGENIC ASTHMA

Question: What percentage of asthma is wholly and what percentage is partly psychogenic, as seen in general practice?

Presented before the Section on Miscellaneous Topics at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

DR. EYERMAN: The psychogenesis of bronchial asthma is an old concept, and this question cannot be answered on a percentage basis without a review of the historical background. The psyche attends all of us at all times in health and in disease. In situations of either health or disease which have a connotation of hopelessness or of doubtful outcome, the psyche will be accentuated. This is particularly true in bronchial asthma because of the inherited significance of breathing, which is one of the most deeplying and fundamental of vital functions. Undoubtedly, the pathologic change is due to an etiologic agent, but just as certainly are the nuances of symptoms due to the disposition, temperament and personality of the patient. Here is the source, of our confusion, both psychosomatists and allergists, for in many patients we are unable to correlate the intensity and the severity of the symptoms with the results of our physical examination and with our concept of the immunologic mechanism. Psychologic factors or psychologic stimuli induce wheezy breathing along facilitated pathways only in persons who have had the pattern of wheezy breathing already established by allergy.

SINUS INFECTION

QUESTION: How often is asthma due to sinus infection and suppuration?

DR. EYERMAN: I do not know, but I believe the figures are given as about 50 per cent in adults and less in the younger decades. The mere expectoration of purulent secretion does not indicate per se that wheezy breathing was due entirely to plugging of the tracheobronchial system by purulent secretion; I am sure that it is the experience of all of you that persons hypersensitive to an allergen who previously always had what was called a cold, with wheezy breathing, while avoiding that allergen go through infections of the upper and the lower respiratory tract without wheezy breathing. The percentage goes up as one gets older, and then infection is the sole cause. The question on the value of positive pressure therapy with and without helium and oxygen mixtures in status asthmaticus has been answered by the discussion of Dr. Piness. My reaction to that question is that oxygen is used in those persons who have clinical evidence of anoxia. The addition of helium makes it easier for them to breathe. We have had to get along without helium, and those persons who needed oxygen seemed to get along all right without it.

PROLONGED ETHER ANESTHESIA

QUESTION: What experience has there been in the treatment of asthma by prolonged ether anesthesia, and may this be used for asthma of infectious origin?

DR. EYERMAN: The only instance in which I have used ether anesthesia has been in intractable asthma. The ether in these instances has been used both by inhalation and by rectal instillation. When used by inhalation, of course it was not with the usual preanesthetic administration of morphine and atropine. When it is so used, such persons have come out of their status asthmaticus. The relief was due to the great amount of expectoration that was induced by ether inhalation anesthesia without preliminary atropine.

TEMPERATURE AND HUMIDITY

QUESTION: What temperature and humidity are best for the asthmatic person to live in, or does this vary from patient to patient?

DR. EYERMAN: I think that it does vary from patient to patient. Certainly those persons in whom infection appeared to be the dominant element seemed to do better in a dry and hot climate. They also have seemed to do well in a dry and cold climate. Further than that, I do not see any more accurate reply.

AGE, POSITIVE PRESSURE, HUMIDITY

DR. PINESS: My experience has been that most of these people who have sinus infection after the age of 40 are usually patients who have had asthma or some other allergic manifestation of the respiratory tract for many years prior to the infection. Regarding the positive pressure therapy in asthma, my associates and I have had experience in only 2 patients. The sad part about it is that the anesthetic department in the hospital in which the positive pressure therapy was given insisted that the patient be given "demerol" before they would give the oxygen. The "demerol" was repeated on two occasions, and the patient, a young woman of about 25, died. I can see no advantage to the therapy. I had nothing to do with prescribing it. As far as humidity is concerned, I think on the West Coast, Arizona, New Mexico and California, where humidity is low, we find that patients who come from the East have just as much trouble as they had in their home towns. Hence, I do not advise anyone to send them to California if it is just for the sake of the humidity.

PSYCHONEUROTIC FACTORS

DR. LOUIS TUFT, Philadelphia: I would like to say something about the psychoneurotic factors in asthma. When the term "psychosomatic" or "psychoneuroses" is mentioned at present, one immediately thinks of a subconscious element along freudian lines that has to do with asthma. One forgets too often a simple form of emotional disturbance that makes many persons with asthma worse. That is the element of fear, particularly in patients who are having asthma for the first time. Patients with asthma react in different ways to fear, just as patients do to pain. Libman pointed out years ago that the patient's reaction to pain will vary from one of complete hyposensitization to one of extreme hypersensitiveness. The same situation exists in asthmatic patients. Some will take the attack in their stride and accept it as something that they have to tolerate. But many asthmatic patients become extremely alarmed, nervous and upset, and unfortunately they are the ones who are given sterile hypodermic injections for relief. When the sterile hypodermic injection affords relief they immediately are classified as psychoneurotic. We physicians would do much more for asthmatic patients if we would spend more time in quiet reassurance and in trying to allay their fears rather than, as has been my experience with some psychiatrists, to ask them many personal questions which are unrelated to their asthma and which only create antagonism.

TEMPER TANTRUMS

DR. BLACK: A small boy had asthma and had learned that he could throw himself into a temper tantrum and produce an attack of asthma. So, when his mother threatened him with corporal punishment, he threatened her with asthma, and he had her effectively blocked off. We found some definite substances to remove from his diet and his environment. Then he found that he could throw his temper tantrum when he wanted to, but he could have no asthma. He cordially hates me because his mother now spanks him. I think that is a good illustration of the influence of psychic reactions on allergic mechanisms.

GAY TREATMENT

QUESTION: What about the so-called Gay treatment for bronchial asthma from Biloxi, Miss.?

DR. TUFT: As Dr. Unger told you, the essential basis of it is drug therapy. I have just been handed the formula by Dr. Piness. It consists of potassium iodide, tincture of digitalis, potassium arsenite solution U. S. P., and phenobarbital sodium. He gives sodium dehydrocholate or dehydrocholic acid, "calmulsion" (a liquid preparation of dicalcium phosphate and vitamin D) or calcium lactate, and a cathartic, usually cascara. Thirty or forty years ago we heard about a remedy that was being distributed in Buffalo. The essential basis of that was potassium iodide. Attention now apparently is being directed to Biloxi, Miss. I think that any benefit which these patients get undoubtedly is due in part to the drugs, especially to potassium iodide and possibly the arsenic, but also to the all-important factor of change of environment. The latter releases these patients both by taking them away from their environmental allergens and either as a form of psychotherapy or as a combination of both.

RADON TREATMENT

QUESTION: What is the general opinion of the radon treatment of Gay and his associates?

DR. TUFT: This refers to Lesley Gay, who reported this along with Dr. Crowe, who originated the treatment for deafness. During the war this investigation was made on aviators who experienced auditory impairment when they were up in the air, apparently as the result of the collection of lymphoid tissue in the nasopharynx. The treatment then consisted in the insertion of radium or radon seeds or in roentgen therapy. Both methods have been used, but I am not prepared to discuss the advantages or disadvantages or to say which method is preferable. Since many asthmatic children have a persistent lymphoid hyperplasia in their nasopharynx even though their tonsils and adenoids have been removed, attempts have been made, therefore, to get rid of the lymphoid collection in the nasopharynx by use of radium or roentgen therapy instead of surgical treatment.

LYMPHOID TISSUE

QUESTION: Is the lymphoid tissue cause or effect?

DR. TUFT: I presume the questioner has in mind whether it is cause or effect in relation to the asthma. That is debatable. Lymphoid hyperplasia is considered by some as being part of the allergy picture, and therefore probably may be causal. If the lymphoid tissue is large enough to cause obstruction, it may induce asthma reflexly, and under those circumstances should be removed by means of radon, roentgen rays or surgical treatment. Whether the effect of radon is specific or nonspecific is difficult to answer. The current belief is that if it affects or benefits the asthma, it does so through its nonspecific effect, just as roentgen treatment of asthma given over the posterior part of the thorax, the spleen or the long bones sometimes temporarily helps the asthmatic patient, presumably through a nonspecific protein effect.

SECTION OF SYMPATHETIC OR PARASYMPATHETIC DORSAL NERVES

QUESTION: Please discuss surgical or chemical section of the sympathetic or parasympathetic dorsal nerves in asthma.

DR. TUFT: As with any chronic intractable disease, asthma likewise has run the gamut of many suggested remedies. One of these was blocking of the parasympathetics either by means of alcohol or by surgical resection of the pulmonary plexus. This is a radical procedure fraught with considerable danger. If I remember correctly, perhaps 15 per cent or more of those patients died either at the time of the operation or not long afterward. I do not remember the exact percentage, but it is high enough to show that it is a radical and dangerous procedure and should not be prescribed for the average patient. I think that Dr. Gay would probably agree that it should be used only as a last resort and that the patient should be warned about the limited possibilities of eventual cure or remission. Some patients, however, did get remissions for periods varying from six months to several years.

DIET FOR PATIENT WITH ALLERGY

QUESTION: Is there any basis for the theory that an asthma due to any allergen may be aggravated by any other protein? Therefore, should a diet high in carbohydrate and low in protein be recommended in treating such a patient?

DR. TUFT: I am not sure what this questioner has in mind. I suppose he means, if a patient is allergic to one food, should you remove other protein foods from the diet? I do not think that is necessary. As a rule, if there is specific sensitization, it is to one food or to a member of a food group, rather than to all protein foods. I do not think that I would recommend a diet low in protein and high in carbohydrate.

SUMMARY

DR. ROBERT A. COOKE, New York: I shall try to sum up the discussion on the treatment of asthma. There are two phases to the treatment. One is symptomatic, the other is etiologic or against the cause itself. Symptomatic therapy is based on the physiologic procedures of getting air into the lungs and clearing the bronchi. One method is to loosen the tenacious secretions in the bronchi. The drug par excellence for that is iodide. When a rapid effect is needed the sodium salt may be given intravenously. Aminophylline, in my experience, gives relief to many patients with severe asthma. The rectal administration of 8 to 10 grains (0.5 to 0.6 Gm.) either in solution or as a suppository often assures a night's rest. Given intravenously, it is more promptly effective. Ephedrine (orally) and epinephrine are the drugs of choice. Epinephrine (aqueous) may be used in a spray or for injection. For prolonged effect injections of epinephrine in oil or gelatine are recommended. Bronchoscopic examination should be done only on selected cases, as effective aspiration of mucus is not easily secured in this way. Possibly the preliminary treatment and medication may be as effective as the actual aspiration. The old fashioned use of ipecac syrup should not be overlooked. The bronchi are better emptied by the act of vomiting, which tends to express the mucous plugs from the bronchi more effectively than does the act of coughing. Rest is essential. Chloral hydrate, paraldehyde or codeine for the cough are helpful drugs but should not be used to the point of decreasing respiration or depressing the center. Nutrition is another important factor. Attention should be paid to fluid intake, minerals and other essential foods. Severely asthmatic patients may do well on intravenous injections of amino acid products and dextrose (2 liters in twenty-four hours) only for one to two days. The diet is then increased to the point of caloric adequacy. Aside from symptomatic measures, treatment should be directed against the cause or against the allergic factor. This means above all a correct diagnosis. Many factors may be responsible for the asthma. Inhalants, foods, drugs and infection may act alone or in combination. I believe that food is not as frequent an excitant as inhalants or infection, but if there are food allergens they should be determined and eliminated. Whether or not infection acts as a primary excitant, it is certain that infection is important in producing asthma. For that reason the antibiotics and the sulfonamide drugs by their effects on acute and chronic infections of the respiratory tract play an important role in controlling asthma. Education and the cooperation of the patient are necessary. Emphasis should be placed on the fact that asthma is not outgrown but that the earlier the patient is seen, given a correct diagnosis and treated, the better the results will be.

Special Article

PRIMARY CARCINOMA OF THE LUNG

EDWARD D. CHURCHILL, M.D.
Boston

This article is the twelfth of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

Primary carcinoma of the lung is a common disease that is usually not difficult to detect even in its early stages. The constructive results of surgical extirpation are favorable when compared with other visceral malignant tumors, and, more important, steady improvement is being recorded. In the past decade the medical profession has made real progress toward earlier diagnosis of this disease, and there are many reasons to believe that the time lag between onset and recognition will be still further reduced. During the same period many of the technical obstacles to the successful management of pulmonary cancer have been surmounted. The operative mortality rate at first appeared formidable because advanced and oftentimes hopeless cases were being approached with technics that were inadequate at the best. As technical problems were solved and more favorable stages of the disease recognized, the operative hazards have been reduced correspondingly.

The problem of primary carcinoma of the lung is now that encountered in all efforts for cancer control—earlier diagnosis. It is doubtful that more radical surgical treatment can be devised that can materially improve results, although further perfection of technics and supportive measures may gain even better immediate results in the poor risk patients that now make up the small group that succumb after operation. There are relatively few patients today who do not have a reasonable chance of weathering a radical removal of the primary growth

Dr. Churchill is John Homans Professor of Surgery, Harvard University, and Chief of the General Surgical Services, Massachusetts General Hospital.

provided the disease is still localized when surgical treatment is undertaken.

Many aspects of pulmonary cancer that are recorded in the vast literature on the subject are of interest only to students of this particular lesion. I shall consider only certain practical aspects of diagnosis and management that are vital to further progress in the control of the disease. They should be of interest to every doctor, if for no other reason than that he himself is a likely candidate for cancer of the lung. Pulmonary cancer is almost as common as cancer of the stomach, and its greatest incidence is in men (80 to 85 per cent) between the ages of 40 and 70.

PREVENTION

Nothing is known about the cause of the disease that can be translated into effective preventive measures. It is possible that an actual increase in the incidence of pulmonary cancer has taken place during the first half of this century. Several statistical studies support such an interpretation. On the other hand, Boyd,[1] who is in a position to speak freely of the shortcomings of pathologists, thinks the disease was not recognized twenty years ago because it was not looked for. At any rate, evidence that pulmonary cancer was on the increase led to several speculations about causative agents, and among other things, cigarette smoking was incriminated. Further knowledge about the nature and the mode of action of carcinogenic agents, and a careful recording of the smoking habits of ample numbers of patients with the disease, provide no factual evidence on which advice to give up smoking for this reason can be based. Exposure to radioactive ores has been correlated with a high incidence of the disease in classical studies on European mine workers. It may be well to bear this in mind.

DETECTION IN APPARENTLY WELL POPULATION

At the present time there is only one practical way to go about detecting early pulmonary cancer in the apparently well population, and that is by roentgen screening. This method will disclose silent neoplasms in the periphery of the lung. The increasing use of roentgen screening as a public health measure for tuberculosis case finding is bringing a few of these asymptomatic cases to light. It will not disclose the early endobronchial growths that have not as yet encroached on the lumen of the bronchus. When bronchial obstruction occurs, symptoms usually bring the patient to the doctor.

However, the age and sex group of men between the ages of 40 and 60, wherein lies the greatest incidence of pulmonary cancer, is probably the most difficult to secure in routine tuberculosis screening. Also, the repetition of the examination at intervals, a precaution necessary in an effective cancer control program, is beyond the range of necessity in checking for active tuberculosis. About all a physician can do to exclude cancer of the lung in a periodic health examination is to inquire about symptoms that may be pertinent and secure a roentgen examination of the chest, preferably by fluoroscopy.

DETECTION BY EARLY SIGNS AND SYMPTOMS

The early symptoms of pulmonary carcinoma are so commonplace that they may not be taken seriously either by the patient or his physician.

Cough.—Cough is the first symptom in over half the cases and a common (90 per cent) manifestation in later stages; but every one coughs, more or less. Patients may be unaware of the fact that they cough. This complaint always should be explored with the query whether there has been a notable change in the cough habits. It is the cough that "hangs on" in an unaccustomed manner that should alert the physician. He should not be misled by the patient who "drops by" to ask for a cough medicine. An acute infection of the respiratory tract oftentimes (10 per cent) provokes the first signs and symptoms of bronchial obstruction. The event may pass clinically as mild pneumonia that responds promptly to chemotherapy or subsides spontaneously. Whether or not a roentgen examination is deemed necessary during the acute phase, it is essential that localized pulmonary infections be followed by roentgen examinations until the lung fields have cleared. A persisting shadow, or one that shows collapse of a segment of lung, indicates further efforts toward diagnostic investigation.

Hemoptysis.—Hemoptysis, when it occurs (5 per cent as a first symptom, and sooner or later in 40 to 50 per cent of cases) is always an indication for thorough diagnostic study. Blood in the sputum in the early stages of pulmonary cancer usually does not take the form of a brisk or profuse hemorrhage. It is more comparable to the small trickle of blood that is detected as "occult" in lesions of the gastrointestinal tract. In the sputum the amount of blood seems insignificant; the regularity and persistence of its appearance are highly significant. Hemoptysis is likely to be the symptom that brings the patient to the physician (30 per cent).

Loss of Weight.—Loss of weight is surprisingly common and many times seems out of proportion to the size and nature of a tumor that is still localized. Loss of weight need not be interpreted as a sign that the tumor has disseminated but, of course, becomes accentuated as the disease progresses.

Pain.—Pain (50 to 60 per cent) when severe is usually a symptom of extension to the parietal or mediastinal pleura. It suggests invasion of the intercostal nerves or the first dorsal root of the brachial plexus. A constant dull pain referred to the back is presumptive evidence of mediastinal invasion and as such points toward an inoperable stage of the disease. Discomfort and other sensations arising in the chest for which the patient cannot always find adequate verbal expression are often described as pain, but not of real severity. They may arise from an inflammatory reaction, the distortion produced by partial atelectasis or from mediastinal involvement.

Wheeze.—The noting of a wheeze (10 to 15 per cent) may be an early symptom that is oftentimes transient. It differs from the wheeze of asthma by being localized as unilateral both by the patient and the examiner.

Pulmonary Osteoarthropathy. — Pulmonary osteoarthropathy with clubbing of the fingers and joint pain is usually a late manifestation, but may be the presenting symptom of a slowly growing and otherwise silent cancer.

Pleural Effusion.—Cancers that originate in the periphery of the lung are oftentimes asymptomatic until they extend to the pleura and spread by dissemination in the pleural space. This event is manifested by pleural effusion, dyspnea and at times pleural pain or discomfort. While it may be the first, and therefore an early happening in the clinical course, it discloses a late and inoperable stage of the disease as far as treatment is concerned. Specimens of the fluid obtained by aspiration characteristically are bloody and contain tumor cells. Small pleural effusions that persist after an episode that has been considered pneumonia should be viewed with suspicion until they absorb.

[1] Boyd, W.: Some Reasons for the Recent Increase of Bronchial Carcinoma; Tr. & Stud., Coll. Physicians, Philadelphia 6:317-328 (Feb.) 1939.

Paralysis of the recurrent laryngeal or the phrenic nerves, obstruction to swallowing, cardiac arrythmia, pericardial effusion and obstruction in the superior vena cava are late manifestations of mediastinal extension of the disease. They usually contraindicate operation.

RESPONSIBILITY FOR EARLY DIAGNOSIS

While the burden of responsibility for the early diagnosis of cancer is commonly pictured as resting on the general practitioner, this is by no means always the case. Many patients today have no regular medical adviser and oftentimes place themselves directly in the hands of specialists in one field or another. The patient's own emphasis on secondary manifestations of the disease may cause him to be directed to specialists who are in a position to lose precious time if the false scent is followed. Cough from any cause may focus the attention of the patient on an inguinal hernia he has tolerated for years, or aggravate a prolapsus uteri, the symptoms from which have long been accepted with resignation. There is a danger that surgical treatment, sound in itself but irrelevant to the real issue, may be undertaken. The wheeze may lead the patient to the specialist in allergy, or hemoptysis send him to the tuberculosis specialist who has been known to undertake a long and laborious search to exclude phthisis by bacteriologic analysis or prescribe a trial period of bed rest. A patient with pulmonary osteoarthropathy based on primary cancer of the lung has been known to follow the devious trail from the expert on arthritis via the exodontist to the specialist in physical medicine. Even the neurosurgeon may come into the picture and confuse a cerebral metastasis with a primary brain tumor.

All physicians, whatever their field of concentration or specialization, must be alert to the early signs of internal cancer if material progress is to be made in the control of the disease. This is particularly true of primary carcinoma of the lung with its varied manifestations.

RESPONSIBILITY OF THE ROENTGENOLOGIST

It would be a rare occurrence to arrive at a diagnosis of primary cancer of the lung in the absence of abnormalities discernible by roentgen examination. Precision in the interpretation of these abnormalities thus runs a close second in importance to an alertness on the part of the physician in recognizing early symptoms. A diagnostic roentgen examination in the presence of signs and symptoms does not mean simply taking a roentgenogram. A comprehensive roentgenographic examination includes lateral films and fluoroscopy in addition to the usual anteroposterior exposures. Oblique exposures, spot films, grid films and tomography may be required. Only after comprehensive study and after giving full weight to the clinical manifestations in conference with the referring physician, should one measure a course of delay against the pursuit of further diagnostic investigation.

It is beyond my competence to discuss the details of roentgen diagnosis of pulmonary cancer. While a surgeon or internist may develop considerable skill in visualizing the pathologic lesions displayed on roentgenograms, a precise diagnostic examination is a matter that had best be left in the hands of the highly skilled specialist in roentgenology. However, in order to maintain his position vis-à-vis the surgeon, the roentgenologist must continually check his interpretations with the actual pathologic changes disclosed at the operating table.

RESPONSIBILITY OF THE EXPERT CONSULTANT

Assuming that the clinical manifestations and roentgen examination point toward the possibility of primary cancer of the lung, it is usually desirable at this point to place the problem before an expert consultant. By an expert consultant is meant some physician or surgeon experienced and familiar with the therapeutic management of the disease as well as with diagnosis. This statement may be challenged by those who would extend the responsibilty of the general medical adviser to piecing together fragmentary bits of technical data derived from several different sources. The reason for the statement is that further diagnostic measures, almost without exception, provide information that bears directly on therapy. If these measures are pursued solely to establish a diagnosis, their contribution to the ultimate problem of therapy is likely to be missed and lead to unnecessary repetition. There is no better example of this than bronchoscopic examination.

Bronchoscopy.—The purpose of bronchoscopy in cancer of the lung extends beyond the removal of a fragment of tissue to confirm the histologic diagnosis. The bronchoscopist notes: integrity or paralysis of the vocal cords; the exact position of the growth with reference to the level at which the bronchus must be sectioned if surgical ablation is undertaken; any widening of the angle of the carina formed by the two primary bronchi that may suggest involvement of the subcarinal lymph node; fixation of the region of the growth, and the gross characteristics of any presenting tumor or ulceration. An expert appraisal of these and other bronchoscopic findings is essential to the final decision regarding treatment. Unless the examination is carried out by an operator who is accustomed to make his observations in terms of the feasibility of a surgical attack on the lesion, the bronchoscopy may have to be repeated by one who is.

Bronchoscopy can be expected to yield a biopsy that provides microscopic confirmation of the diagnosis in 60 to 70 per cent of cases. In other words, 30 to 40 per cent of primary cancers of the lung are so situated that they cannot be reached by the biopsy forceps. These proportions are based on series of cases heavily weighted with advanced and inoperable cases, and so are not applicable to the disease in early and surgically favorable stages. Negative findings on bronchoscopy may be of no significance if it is recognized by preliminary roentgen localization that the lesion is inaccessible; for example, in certain segments of the upper lobe. On the other hand, negative findings may be extremely important if the area under question is readily accessible. Improvements in the optical system of bronchoscopic instruments have made visualization of the segmental bronchi of the upper lobes feasible.

Cytologic Methods.—Increased precision in the diagnosis of the disease is provided by methods for recognizing malignant cells in the sputum. In 1935 Dudgeon and Wrigley [2] showed that this method was reliable, and many subsequent observers have confirmed the practical usefulness of the technic.

The method has been modified and its effectiveness increased by examining a specimen of secretion secured directly from the region of the lesion at the time of bronchoscopy. This requires accurate localization of the suspected lesion to a bronchial segment by preliminary roentgen examination and insertion of an aspirating tube into the lumen of the corresponding bronchus. Cells obtained in this manner appear in greater numbers and show less degenerative change than those expectorated in the sputum. Herbut and Clerf[3] examined bronchial secretions obtained by this procedure by the Papanicolaou technic in 30 consecutive cases of primary pulmonary carcinoma. Cancer cells were demonstrated in 22 cases, but biopsy specimens of tissue showed cancer in only 11 cases. Bronchoscopy failed to disclose cancer in 7 cases in which cancer cells were present in the aspirated secretions.

---

[2] Dudgeon, L. S., and Wrigley, C. H.: On the Demonstration of Particles of Malignant Growth in the Sputum by Means of the Wet Film Method, J. Laryng. & Otol. **50**: 752-763 (Oct.) 1935.

Negative results of cytologic studies are of questionable significance, and positive results are valid only when the interpretation is made by an experienced observer. A positive finding by [illegible] thod is not as yet given the weight [illegible] tissue biopsy. It is one additional link in the chain of evidence that requires clinical or roentgenographic support.

Bronchography.—Instillation of iodized oil is rarely a useful aid to the diagnosis or localization of pulmonary cancer and should be used only to answer some highly technical question. The ill advised use of iodized oil as a general diagnostic measure or simply to demonstrate bronchial obstruction may obscure or complicate subsequent roentgenographic studies. There is little to be learned from instillation of iodized oil that cannot be observed with spot films, grid films or tomography. This is true, not only for pulmonary cancer, but in other diseases of the chest as well, the notable exception being bronchiectasis. Even here the chief value of the bronchogram lies in the planning of a surgical program, not merely in arriving at a diagnosis that usually can be established by other means.

Differentiation of Primary and Metastatic Neoplasms.—Because the lung is so commonly a site for the development of metastases from primary growths in other organs, this diagnostic question is one that is raised repeatedly. When a primary or recurrent autonomous cancer is actually present elsewhere, the likelihood that the pulmonary lesion is a secondary deposit is, of course, great. Multiplicity of pulmonary lesions is also strong evidence of metastatic disease. Merely the history of the surgical ablation of a malignant growth in the past, if a reasonable period of time has elapsed without evidence of recurrence of the disease and the lesion in the lung is a solitary one, should not close the door to a consideration of surgical therapy.

The roentgenologist is likely to raise the question of a metastatic origin when the abnormal shadow lies in the periphery of the lung and is spherical. When such a lesion is encountered, and it will commonly be found in a patient with few, if any, clinical manifestations, a painstaking physical examination must be carried out not only to detect a primary source but to be certain that other nodules do not exist from which a biopsy can be obtained more readily than from the one in the lung. In view of the frequency with which renal cell carcinoma casts a solitary metastasis to the lung, pyelography should be carried out. The ultimate decision as to whether the pulmonary lesion should be approached surgically is based on a careful weighing of many variables that never take the same pattern in two different cases. Alexander[4] has assembled the experience of several surgeons with the removal of metastatic neoplasms in the lung.

A rare form of metastatic disease results from a metastasis to the wall of a bronchus. This occurrence closely simulates primary neoplasm of the lung as it may produce bronchial obstruction, hemoptysis, malignant cells in the sputum and positive bronchoscopic findings. No one of these is commonly present with peripheral pulmonary metastases, although hemoptysis is not as rare as it was formerly thought to be.

Differentiation of Primary Cancer of the Lung and Tuberculosis.—A round and apparently "stabilized" focus of the adult type of postprimary tuberculosis may closely resemble an early peripheral neoplasm. So also may the rare postprimary nodule of hemic origin that is characterized by dense fibrosis and in many instances by a retarded tendency toward roentgenographically demonstrable calcification. An intensive search for tubercle bacilli may provide an answer in the first mentioned form of the disease, but will not produce positive evidence in the latter.

Depending on the collateral lines of evidence, surgical exploration of the lesion may be required. The operator should not commit himself to total pneumonectomy, however, until further evidence is obtained at operation. Taking of a biopsy specimen of the dense fibrotic nodule of hemic origin may be accomplished by resection en bloc for immediate pathologic diagnosis. Taking of a biopsy specimen of a circumscribed nodule of adult type postprimary tuberculosis should take the form of a lobectomy, because these lesions are filled with caseous material heavily loaded with tubercle bacilli. When carried out with technical finesse, such a "biopsy" oftentimes proves to have been a remarkably effective method of treating the tuberculosis before frank cavitation is established.

Summary.—This review of the responsibilities of the expert consultant makes it obvious that he should have at his command a number of diagnostic technics that range from careful case history taking and physical examination to thoracotomy for biopsy of a doubtful lesion. These responsibilities must be faced in logical sequence and carried through without delay. On the other hand, the consultant may indulge in certain assumptions relative to his responsibility that are not altogether warranted. Attention is called to these because they may retard the development of that close relationship between practitioner and specialist that is desired to promote progress in cancer control. They also directly influence the extent to which the patient will respond to the educational efforts that urge him to consult a physician in regard to early symptoms.

One of these assumptions is that the expert must invariably exclude any possibility of cancer, however remote, by resorting to major diagnostic technics without regard to whether the clinical problem under consideration indicates their use. Another false assumption is that a presumptive clinical diagnosis always must be extended to histologic confirmation despite the fact that the course of management is obviously not going to be altered by the reading of the microscopic slide. Finally, in deciding on the course that the management of an advanced case is to take, surgical exploration is oftentimes proposed as the "only chance" and as such, one that cannot be denied the patient. In their quest for scientific exactitude the members of the profession must not confuse the scientific precision with which certain parts of the evidence can be formulated with the broad responsibility of weighing evidence as a whole. Courts of law may exact severe or even capital punishment if the evidence as a whole is judged valid "beyond any reasonable doubt." It is the responsibility of the consultant in conference with the family medical adviser to determine whether the "only chance" offered by surgical treatment is in truth a reasonable chance, or whether the cancer is surgically "out of bounds" beyond any reasonable doubt.

ALTERNATIVE FORMS OF TREATMENT

There is no possibility of obtaining a lasting arrest of the disease unless the entire growth can be extirpated. Roentgen therapy appears to halt the progress of a few cancers of the lung temporarily. Occasionally actual regression takes place for a period of several months. Applied indiscriminately to advanced cases, roentgen therapy contributes little either to survival time or relief of physical suffering. The nitrogen mustard compounds produce transient and incomplete regression in about one half the patients treated.[5] Castration and the use of estrogenically active substances have been explored on the basis of the unequal sex incidence of the disease, but no indication of effectiveness has appeared. The crucial decision therefore lies in the judgment regarding the applicability of surgical procedures.

INDICATIONS THAT THE CANCER CANNOT BE EXTIRPATED

Extension to Pleura.—A pleural effusion, usually bloody and containing cancer cells, can be interpreted as definite evidence that the cancer has extended beyond the bounds of surgical extirpation. While patients with this form of the disease suffer from shortness of breath, progressive anemia and cachexia, they usually are not subject to severe pain or distressing cough. Aspiration of the fluid and replacement with air afford partial symptomatic relief.

If the diagnosis is in doubt because cancer cells cannot be demonstrated, the replacement of the pleural effusion with air may bring pleural nodules into view on roentgen examination. A biopsy can be obtained with the aid of the thoracoscope or by a limited thoracotomy with the patient under local anesthesia. A pathologic confirmation of the diagnosis is desirable in this type of the disease, as radiation therapy may be helpful and as a general rule heavy dosage should not be administered without accurate knowledge that the disease being treated is cancer.

Extension to Lymph Nodes.—An exacting palpation of the supraclavicular fossae, neck and axillas should be carried out in every case. The removal of a palpable node with the patient under local anesthesia may confirm a presumptive clinical diagnosis and at the same time demonstrate that the cancer has extended beyond the limits of surgical extirpation. This is a less trying procedure to the patient than bronchoscopy and can be substituted for it not infrequently.

Extension to mediastinal lymph nodes is difficult to establish by roentgen examination alone. Presumptive roentgen evidence may become determinative when combined with bronchoscopic fixation of the growth and pain referred to the back.

Lymphatic Dissemination.—Diffuse spread in the lymphatic channels of one or both lungs with the development of small nodules immediately beneath the visceral pleura may be detected on roentgen examination. Thoracoscopy can be an adequate substitute for a formal thoracotomy.

Hematogenous Metastasis.—Spread to the liver may be suggested by the increased size or palpable nodularity of that organ. Peritoneoscopy is a simple procedure that confirms the diagnosis. Headaches or other cerebral symptoms call for a painstaking neurologic examination, including the determination of the visual fields.

Painful Apical Syndrome.—Pain referred down the arm, a Horner's syndrome, and roentgen evidence of erosion of the first and second ribs are often referred to as Pancoast's syndrome. It is usually produced by a primary cancer of the lung in the superior pulmonary sulcus. A cancer that produces this syndrome is beyond the bounds of surgical extirpation, and the severe pain cannot be relieved by local resection, or division of the intercostal nerves. The pain is oftentimes excruciating and the course of the disease agonizingly slow. Relief should be sought by tractotomy or high chordotomy.

Histologic Type of the Tumor.—The prognosis following surgical extirpation has not been fully correlated with the predominant cytologic characteristics of cancers of the lung. The evidence that exists, however, confirms the reasonable hypothesis that growths with highly undifferentiated cells are rapidly invasive and tend to metastasize early. The same may be said for the so-called oat cell type. Significant results achieved by the surgical extirpation of cancers of these morphologic types are rare. A biopsy that demonstrates a highly undifferentiated or oat cell cancer is presumptive evidence that complete surgical extirpation is a remote possibility.

Nerve Paralysis.—Paralysis of the recurrent laryngeal nerve is evidence of mediastinal invasion at a level that precludes complete surgical ablation. Cancers that have produced phrenic nerve palsy may be resectable grossly. It is significant, however, that Ochsner, DeBakey and Dixon[6] analyzed the survival period in their cases from the standpoint of whether the growth was limited to the lung or had extended beyond it by encroachment on contiguous structures or by regional lymph node metastases and found that only 2 of 27 patients with such extension demonstrated at operation survived beyond a three year period, and none beyond six years.

SURGICAL TREATMENT

Operability.—The experience of many different surgeons in the United States and elsewhere has been surprisingly uniform in the results achieved by surgical extirpation. Apparent differences in the statistical tables that record this experience are usually artifacts developed by the terminology employed, the calendar years covered by the report, the selection of cases and other variable factors.

An analysis of the results of surgical therapy customarily starts with those patients that are referred to a surgeon for consideration of operation. This base line ignores the large number of patients in whom a diagnosis is never made or whose disease is judged so far advanced that surgical consultation is superfluous. It is thus impossible to determine with exactitude the extent to which surgical procedures can be an effective control measure in the population at large. Surgical efforts have rarely been measured against the magnitude of the problem as a whole. Few surgeons, particularly those whose cases are assembled from a private clientele, appear to be aware of the selection that has taken place before their own "series" was assembled.

In 996 cases with the clinical diagnosis of bronchiogenic carcinoma at The Brompton Hospital for Diseases of the Chest, in London,[7] from 1937 to and including 1944, only 15.3 per cent (152 cases) were judged suitable for a thoracotomy. In cases in which thoracotomy was done, extirpation of the growth was performed in

[6] Ochsner, A.; DeBakey, M., and Dixon, J. L.: Primary Cancer of the Lung, J. A. M. A. **135:** 321-327 (Oct. 11) 1947 (revision by personal communication to the author, March 1948).

[7] Björk, V. O.: Bronchiogenic Carcinoma, Lund, Berlingska Boktryckeriet, 1947; Acta Chir. Scandinav. (suppl. 123) **95:** 1-113, 1947.

75 cases, or 7.5 per cent of the whole. Despite this gloomy picture, which possibly is attributable in part to the war years, the cases considered favorable for thoracotomy increased from 8.2 per cent in 1937 to 25.6 per cent in 1944. Furthermore, resectability increased from 5.1 per cent in 1937 to 13.5 per cent in 1944. These basic figures from the Brompton Hospital are significant because during this period a vigorous surgical program was being pressed by Edwards, Roberts, Price Thomas and Brock. Their importance lies in the base line provided by the population of a large hospital admitting persons with medical and surgical diseases of the chest.

The range of applicability of surgical procedures provided by reports from surgeons in the United States is more favorable, but these reports are heavily weighted by collecting of patients from a wide area because they were judged favorable for operation. They do not accurately represent the state of affairs relative to the disease as a whole. Nine reports (Adams,[8] Burnett,[9] Churchill,[10] Clagett and Brindley,[11] Graham,[12] Jones,[13] Lindskog,[14] Ochsner, DeBakey and Dixon,[6] Overholt[15]) published since 1940, record 1950 cases. In 782 (40 per cent) of these thoracotomy was done, and in 432 cases resection was performed (22 per cent).

It should be recalled that the first total pneumonectomy that launched the surgical attack on pulmonary cancer was performed in 1933 (Graham)[16] and that several of the series of cases referred to date back to that year or shortly thereafter. There is an encouraging trend toward a higher proportion of operable cases in the more recent reports and in current experience.

When an attempt is made to estimate the proportion of patients who die in hospitals as an immediate result of the operation or its attending complications, the changing background provided by technical improvements, chemotherapy, blood transfusion and other adjuvants to surgical management necessitates yearly corrections. In addition, the removal of growths that are not localized to the lung has carried a higher mortality rate than is encountered when dealing with the more favorable localized growths that are coming to the surgeon with increasing frequency. The 1947 report of Jones,[13] based on the experience of the preceding four years, gives a better index of what is going on now than a summation of earlier experience. A total of fifty-two pneumonectomies with but 2 hospital deaths yielded an actual operative mortality of less than 4 per cent. This was accomplished on the basis of performing thoracotomy in 33 per cent of the cases diagnosed and carrying out pneumonectomy in 20 per cent of the total cases. Similarly, in 1946, Adams[8] on the basis of a 31.4 per cent rate of resection recorded a hospital mortality rate of 3.3 per cent in his most recent thirty consecutive resections.

These figures are startling, as they show that the operative mortality rate of total pneumonectomy for pulmonary cancer can now be made equivalent to that of partial gastrectomy for malignant lesions of the stomach (3.2 per cent, Mayo Clinic, 1945), and considerably lower than that of total gastrectomy (16.7 per cent, Mayo Clinic, 1945). The resectability rate for malignant lesions of the stomach, i.e., the ratio of patients who undergo resection to the total patients in whom the diagnosis is made, is somewhat higher (38 per cent).

Survival Expectancy.—Careful follow-up statistics that measure the survival expectancy in pulmonary malignancy treated by surgical resection have not as yet leveled off to even an approximation of accuracy. It is probably more informative to consider that Graham's patient, in whom a total pneumonectomy was performed for squamous cell carcinoma in 1933, is still alive and well than it is to attempt to interpret the preliminary analyses that have been placed on record.

There are several variables to be considered, not the least of which is whether the growth appeared to be localized to the lung at the time of resection or whether it gave evidence of having extended to the mediastinum, either by regional metastases or encroachment on contiguous structures. Ochsner, DeBakey and Dixon[6] performed resection in 43 cases in which the growth was considered to have extended beyond the lung and for which sufficient time had elapsed so that the three year survival rate could be computed. Five of these 43 patients were surviving at the end of three years. Of 18 patients for whom a five year survival rate could be computed, only 1 was alive. Not a single instance of survival as long as one year is recorded for 244 untreated patients.[17] It seems reasonable to suppose, therefore, that removal of the lung bearing the primary growth rids the patient of certain complications of the disease that accelerate his death. The relentless progress of the disseminated cancer continues.

This concept that the local primary growth not only causes distressing symptoms, as in cancer of the rectum, but accelerates death, as in obstructing cancer of the pylorus or esophagus, is well known to surgeons but needs far greater emphasis elsewhere in the profession. Surgical treatment of cancer is too often harshly judged as being futile on the grounds that it fails to produce a lasting cure, rather than on the fact that it makes the best terms possible with a disease that is already hopeless.

Another variable in the reports of survival centers in the pathologic classification of the peculiar tumor known as bronchial adenoma. Arguments as to whether this neoplasm is malignant have obscured certain clinical facts about which there can be no difference of opinion. Clinically, the bronchial adenoma pursues a leisurely and protracted course, and when resected, recurrence or subsequent dissemination is practically unknown. The tumor is rare in comparison with the forms of pulmonary carcinoma under discussion ; yet the inclusion of a few cases when the survival expectancy following operation is being tabulated will afford an unduly optimistic interpretation of results.

Adjuvant Surgical Measures.—Extension to the parietal chest wall is likely to occur with peripheral squamous cell cancers. The pain caused by this extension in inoperable cases may be alleviated by section of the intercostal nerves or may require chordotomy. Drainage of an abscess or empyema may reduce a productive [illegible] The effects [illegible] of chemotherapy are transient and incomplete when the pneumonitis or abscess is peripheral to a blocked bronchus.

The Operation.—The operation of total pneumonectomy is so standardized that it warrants little comment. The lung is mobilized, if adherent, and the vessels secured by individual ligatures. The bronchus is divided and closed by interrupted sutures. Some operators place emphasis on the use of stainless steel wire sutures, but the important technical precaution appears to lie in the avoidance of necrotizing clamps and sutures. The closed bronchial stump is covered by a flap of pleura, a mobilized intercostal muscle and pleura or a free graft of lung tissue.

The chest is closed without drainage, leaving the dead space to be obliterated partly by organizing exudate and partly by displacement of the mediastinum, rise of the diaphragm and retraction of the chest wall. Some surgeons find that thoracoplasty is advisable in many cases after a certain amount of time has elapsed. Others rarely find it necessary to carry out this procedure. Certainly it should be done for good reason, if at all.

The age group of patients concerned brings a substantial incidence of cardiovascular complications. Cardiac arrhythmia, particularly auricular flutter, may occur in the postoperative period. For this reason preoperative preparation with quinidine is recommended.

Blood lost at the operation should be replaced in volume, but, because of the dangers of edema in the remaining lung, additional fluids are administered in moderation. Oxygen therapy is usually employed during the first twenty-four hours. The total hospital stay after the operation has been greatly reduced and now rarely exceeds two weeks. Early ambulation is beneficial and there is no danger of incisional dehiscence or hernia.

A well administered anesthetic is vital to the patient and the technical steps of the operation. A few anesthetists continue to magnify the technics and complicate the procedure with cumbersome appliances, but as a general rule anesthesia for major intrathoracic procedures has settled down to standardized intratracheal technics that require little comment. The important qualities demanded of the anesthetic agent are, first, that it have as wide a margin of safety as possible and, second, that full anesthesia can be maintained with a high percentage of oxygen in the mixture.

Position on the table, incision, instruments and other details are matters that are best left to the operating surgeon, who is assumed to have sufficient competence to undertake the procedure.

The surgical excision of cancer of other organs began with limited resection and extended to radical resection. In contrast, the surgery of cancer of the lung, except for a few sporadic attempts, started with total pneumonectomy. This in part accounts for the uniformity of results that have been achieved. It is customary for surgeons to take the position that total pneumonectomy is the only acceptable form of operation. If the mortality rate of total pneumonectomy is the same as that of a more limited resection, and the life expectancy rate or disability of persons with one lung equal to that of persons after a lobectomy, the matter can be closed. As long as any disparity in these values exists, however, the question of the place of less radical procedures in carefully selected cases must be kept open.

NONSURGICAL TREATMENT

As long as only 1 or 2 patients out of 5 that come to the surgeon have resectable growths, a patient should be informed before the consultation that his particular problem may or may not be solved by surgical procedures. A patient is likely to come to the surgeon with high hopes that if the growth can be resected his life will be saved but that if the operation cannot be performed he is doomed to die. Even a limited faith in any alternative method of management has been completely destroyed. It is less disturbing to the patient and to an apprehensive family to speak of surgical operation as one of several methods of management that may have to be pursued. It can be explained to the patient that certain forms of his disease can best be managed by surgical procedure and others by radiation therapy, nitrogen mustard, and so on; that sometimes it is necessary actually to look at the diseased area and determine its position and nature by thoracotomy before the decision as to the most effective method of management for his particular case can be made.

When surgical procedures are found impossible, great comfort is derived from the knowledge that some constructive course can be taken, even though the chances of success may be slight. The patient will rarely concern himself about the magnitude of this chance if he is led to feel that everything possible is being done.

There is no short cut that can teach a surgeon what to say and how to say it when he is faced by patients with inoperable malignant disease. He may elect to remain on the purely technical level, a position that certainly is the least troublesome and time consuming. It may be found that this is the only position that can be taken in certain situations. On other occasions, the surgeon may be the only person in a position to guide the patient and his immediate family through a trying period. This takes time. While the exploratory thoracotomy that reveals an inoperable growth may be completed in three quarters of an hour, several hours must be spent with the family, the patient and in conference with the physician who is to take over the daily management of the case after discharge from the hospital.

Surgeons today, struggling to keep abreast of a heavy load of technologic detail, unfortunately find little time for these matters. If they are to maintain their position as doctors in contrast to artisans, the responsibilities entailed must be faced.

Clinical Notes, Suggestions and New Instruments

FLUID REPLACEMENT WITH HALF STRENGTH SODIUM CHLORIDE SOLUTION

MANUEL E. LICHTENSTEIN, M. D.
Chicago

Loss of fluid in intestinal obstruction results from two developments following onset of the condition. First, frank loss of secretions occurs as a result of (*a*) vomiting, (*b*) stagnation of secretions above the level of obstruction and (*c*) suction or siphonage instituted when the patient is placed under management. Second, loss of income is sustained as a result of abstention from food and beverages.

The amount of loss in the first of these developments varies with the volumes vomited, stagnant in the intestinal lumen and aspirated by suction or siphonage. Whatever this volume may be, it is composed of water with organic and inorganic substances the most important of which is sodium chloride. The concentration of the salts in the gastrointestinal secretions is ap-

---

From the Division of Surgery Northwestern University Medical School and the Cook County Graduate School of Medicine.

proximately that of the same salts in the blood serum.[1] To compensate for this loss it has been suggested that 0.9 per cent sodium chloride solution be administered with a volume replacement equal to the volume lost.

The loss of fluid due to lack of income amounts to 2 to 3 liters daily. This amount affords 1 to 1½ liters of water for the adequate removal of waste materials in the urine (specific gravity 1.015 to 1.025) and 1 to 1½ liters for regulation of body temperature through cutaneous evaporation, perspiration and pulmonary ventilation. In any loss of fluids output of urine diminishes immediately, while regulation of body temperature remains active. This is made possible by use of the water reserves in the body. When the latter fails, hyperthermia and other evidences of hypohydration become manifest. Since under normal conditions this 2 to 3 liters is essentially water with a sodium chloride content of approximately 5 Gm., a parenteral replacement for this loss would be 2 to 3 liters of water (5 per cent dextrose in distilled water) with an addition of about 5 Gm. of sodium chloride (500 cc. of 0.9 per cent sodium chloride).

Thus, in intestinal obstruction part of the fluid required for replacement of loss is equivalent to 0.9 per cent sodium chloride solution, while the balance of the loss is water without sodium chloride. A solution containing 0.45 per cent sodium chloride and 2.5 per cent dextrose (an isotonic solution) would seem to be an appropriate solution for fluid replacement. This solution does not supply too much sodium chloride, nor does it fail to supply enough. Five liters of this solution for hydration would supply 22.5 Gm. of sodium chloride. This would be adequate for most patients with intestinal obstruction who have lost 2 to 3 liters of intestinal secretions, while awaiting relief from any method of planned conservative therapy or surgical therapy. If parenteral therapy is continued for several days the half strength solution would adequately supply the mineral needs while secretions are not being absorbed.

It must be understood that administration of fluid is not a substitute for surgical treatment in intestinal obstruction. Administration of fluid, however, does hydrate the patient, makes possible urinary excretion and regulates body temperature. The minerals in the fluids administered supply the electrolytes lost in the intestinal secretion and restore the blood levels of these elements to the normal. A judicious selection of isotonic solutions with and without sodium chloride would, of course, supply enough and not too much sodium chloride. However, the half *strength sodium chloride solution is an assurance that no excess* of salt would be administered.

Manufacturers of parenteral fluids have not included the 0.45 per cent sodium chloride in 2.5 per cent dextrose solution in their line. This solution has been used with satisfactory results for many years on many services at Cook County Hospital. Dr. Bernard Fantus advocated its use and pointed out the dangers of the continuous use of normal sodium chloride solution.[2] It would be a progressive measure if this solution were more readily available in all hospitals. It would permit the patient to be freed from the dangers of the excessive administration of sodium chloride, in a condition in which sodium chloride is of utmost importance. In addition, for the conditions in which little loss of sodium chloride occurs and water replacement is necessary this half strength solution presents a safety factor in that it does not supply too much salt.

Council on Pharmacy and Chemistry

The Council has authorized publication of the following reports.

Austin Smith, M.D., *Secretary.*

RECOGNITION OF ADDITIONAL GENERIC NAMES FOR COUNCIL-ACCEPTED PRODUCTS

In pursuance of its policy requesting the use of generic or unprotected names for products accepted for inclusion in New and Nonofficial Remedies under protected names, the Council asks the interested firms for suggestions, which are considered by the Council's Committee on Nomenclature and from which are chosen terms eligible for recognition. Recently the Council voted to recognize the following generic terms:

BISMUTH ARSPHENAMINE SULFONATE for Bismarsen-Abbott Laboratories.

ACETYPYROGALL for Lenigallol-Bilhuber-Knoll Corporation.

DIALLYLBARBITURIC ACID for Dial-Ciba Pharmaceutical Products, Inc.

IODINATED CASTOR OIL for Riodine-Gallia Laboratories.

PHENYLPROPYLMETHYLAMINE for Vonedrine-the Wm. S. Merrell Company.

BETETHAMINE for Monocaine-Novocol Chemical Mfg. Co., Inc.

SODIUM BISMUTH THIOGLYCOLLATE for Thio-Bismol-Parke, Davis & Company.

METHENAMINE TETRAIODIDE for Siomine-Pitman-Moore Company.

ALLYL BARBITURIC ACID for Sandoptal-Sandoz Chemical Works.

PSYLLIUM HYDROPHYLIC MUCCILLOID for Metamucil-G. D. Searle & Company.

Additional generic names will be published as soon as the Council has considered them.

GENERIC TERM FOR DIOCYL HYDROCHLORIDE: DICYCLOMINE HYDROCHLORIDE

The Wm. S. Merrell Company requested the Council's recognition of the proprietary name Diocyl Hydrochloride and the generic designation Dicyclomine Hydrochloride for β-diethylaminoethyl-1-cyclohexylcyclohexane-carboxylate.

On the basis of the information submitted by the firm, the Council voted to recognize the stated names as protected and generic terms, respectively, for this compound.

ALCOHOL-DEXTROSE and DEXTROSE-VITAMIN SOLUTIONS FOR INTRAVENOUS INFUSION NOT ACCEPTABLE FOR N.N.R.

Solutions for intravenous infusion of fluids, dextrose, salts or ions have been long established as a recognized form of replacement therapy in patients having a temporary deficiency of such essentials because of surgery or emergency illness. In the treatment of shock, the injection of crystalloids has been largely superseded by plasma or serum. For intravenous feeding, solutions of protein hydrolysate with dextrose are supplementing the use of dextrose alone as a source of caloric energy to sustain the nutritive requirements of such patients.

Recently the Council was requested to give consideration to a preparation of ethyl alchol 5 per cent and dextrose 5 per cent in isotonic sodium chloride solution for intravenous infusion postoperatively to provide the combined sedative-analgesic effect of alcohol with the caloric value of alcohol and dextrose in a single preparation. The Council was subsequently requested to consider a similar alcohol-dextrose combination, available in concentrations of either 5 or 10 per cent alcohol with 5 per cent dextrose in either distilled water or isotonic sodium chloride solution and with or without the addition of the vitamins, niacinamide, riboflavin and thiamine hydrochloride. The Council also gave consideration to a dextrose-vitamin mixture available in concentrations of 5 and 10 per cent dextrose with the same three vitamins in either distilled water or isotonic sodium chloride solution The evidence advanced in support of these preparations included reports from the medical literature on the use of alcohol for intravenous infusion as a postoperative sedative or analgesic and as an adjunct in the treatment of certain diseases, including delirium tremens. Other reports concerning the need for certain vitamins essential to the metabolism of carbohydrate and as an adjunct in the treatment of alcoholism were also submitted.

---

[1] Gamble, J. L.: Express Cellular Fluids, Cambridge, Mass., Howard University Press, 1942.

[2] Fantus, B.: The Technic of Medication: Intravenous Osmotherapy, J.A.M.A. 87:411-413 (Aug. 7) 1926; Chicago, American Medical Association, 1938, chap. 8, pp. 490-495.

In reviewing the evidence for the submitted mixtures the Council found the reports poorly documented and the evidence unconvincing. With regard to the intravenous use of alcohol-dextrose preparations, it was pointed out that while alcohol so administered is not necessarily potentially dangerous, its peripheral vasodilatory effect could be deleterious in the presence of shock or impending surgical shock. It was considered that, although such a solution might conceivably be found useful when other narcotics were contraindicated, alcohol is also subject to the production of tolerance, leaves much to be desired as a sedative and is only a feeble stimulant of respiration. There are other methods of combating postoperative pain and restlessness that do not require the injection of large volumes of expensive solution. Concerning the caloric value of alcohol as a supplement to dextrose it was pointed out that while 1 cc. of absolute alcohol yields approximately 8 calories, the high specific dynamic action of alcohol would negate a fair amount of what is gained by its administration; furthermore, additional dextrose could accomplish the same purpose.

Claims for the intravenous use of alcohol in the treatment of pneumonia, pulmonary abscess or gangrene were held to be misleading. It was further indicated that the use of alcohol in the treatment of delirium tremens had been abandoned by many clinics because it constitutes no cure and does not relieve the disturbances associated with this disease any better than conventional methods of therapy.

The addition of vitamins to either alcohol and/or dextrose solutions for intravenous injection was held to represent a form of shotgun vitamin therapy that is overelaborate. It was agreed that although carbohydrate requires thiamine and riboflavin for its complete metabolism and such components of the vitamin B complex may have some use in overcoming deficiencies in alcoholic persons, it is not established that a single dose of either alcohol or dextrose, or both, requires the simultaneous administration of vitamins in the same solution. It was pointed out that patients receiving parenteral solutions of this type do so for the relatively short period of postoperative recovery, so that any acute deficiency of vitamins is not significant. It was emphasized that employment of such therapy presupposes that necessary amounts of the vitamins needed are not available within the body, a state of deficiency which is not established or likely in the conditions for which the solutions are proposed. It was further indicated that in prolonged undernutrition vitamins in larger amounts than are provided by ready-made solutions may be required, which need, can therefore be met by more rationally separate administration of the vitamins or their addition to a simple infusion solution in dosage requisite to meet the demands of such patients. The marketing of ready-made solutions containing vitamins was held to add materially to the cost for the patient and to serve no useful purpose.

The Council concluded that alcohol-dextrose and dextrose-vitamin solutions for intravenous infusion are not acceptable for inclusion in New and Nonofficial Remedies because they are unnecessarily elaborate and the claims for their use are not supported by convincing evidence of the need for or value of infusion of this type.

The drug will continue to be available only in capsule form for oral administration. Since it is important to hold narcotic administration to a minimum, to facilitate this and to permit adjustment of dose to the need of a particular case each capsule will contain 3 mg. of metopon hydrochloride. The minimal effective analgesic dose in nontolerant persons is 6 mg. Therefore, the dose is two capsules for persons who have not taken morphine and related substances previously, and it may be three or more capsules for persons already tolerant to morphine and the like. Institution of treatment with metopon hydrochloride in the latter group should be accompanied by rapid reduction rather than abrupt discontinuance of the previous medication.

The Committee on Drug Addiction and Narcotics of the National Research Council through its secretary (Nathan B. Eddy, National Institute of Health, Bethesda 14, Md.) will be glad to continue its correspondence with physicians in regard to their experience with metopon hydrochloride and to advise them on the use of the drug.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

SULFADIAZINE (See New and Nonofficial Remedies, 1947, p. 120).

The following dosage form has been accepted:
McNEIL LABORATORIES, INC., PHILADELPHIA.

Liquoid Sulfadiazine: 120 cc. and 480 cc. bottles.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1947, p. 347).

The following dosage form has been accepted:
ESTRO CHEMICAL CO., INC., NEW YORK.

Solution Diethylstilbestrol in Oil: 1 mg., 2 mg., and 5 mg. per cc.; 1 cc. ampuls and 30 cc. vials in corn oil. Preserved with chlorobutanol 0.5 per cent.

NIKETHAMIDE (See New and Nonofficial Remedies, 1947, p. 260).

The following dosage form has been accepted:
PREMO PHARMACEUTICAL LABORATORIES, NEW YORK.

Solution Nikethamide 25% W/V: For oral use 15 cc., 45 cc. and 480 cc. bottles. For parenteral use 1.5 cc. and 5 cc. ampuls.

ESTRONE (See New and Nonofficial Remedies, 1947, p. 341).

The following additional dosage forms have been accepted:
PARKE, DAVIS & CO., DETROIT.

Solution Theelin in Oil: 1 mg. (10,000 international units) in 10 cc. vials in peanut oil. Preserved with benzethonium octyloxyacetate 1:4,000.

Aqueous Suspension Theelin: 1 mg. (10,000 international units) and 5 mg. (50,000 international units) in 1 cc. ampuls. Preserved with benzethonium octyloxyacetate 1:4,000.

EDITORIAL ANNOUNCEMENT

The absence of the compositors from their work continues. This issue of THE JOURNAL has been prepared in part by the use of Vari-Typer machines.

MEDICAL RESEARCH

Volume five of the Steelman Report on "Science and Public Policy" concerns itself largely with the manner in which the federal government can most effectively promote and encourage scientific research on medical problems. The nation invests some $110,000,000 annually for scientific research and development in medical and allied fields as contrasted with ten times that amount for all other forms of scientific inquiry. The Committee on Medical Research of the Office of Scientific Research and Development devoted its attention to the solution of practical problems. Establishment of a committee composed of government and nongovernment medical scientists has been recommended to suggest a comprehensive program to utilize most effectively all the nation's resources. Recommendations are that funds be distributed for basic and applied research and for training of investigators. Expenditures for medical and allied research, according to the Steelman report,[1] should be at least tripled by 1957 to not less than $300,000,000 yearly.

Of funds from all sources devoted to medical research in 1947, industry contributed 45 per cent, federal, state and local governments 28 per cent and foundations 13 per cent. Comment was made that the private foundations such as the Rockefeller Foundation, Commonwealth Fund, the Kellogg Foundation and the Milbank Memorial Fund, which have contributed so greatly to medical research in the past, seem to be contributing less to the postwar requirements. According to the report, dissipation of their capital resources probably will continue and may mean their eventual dissolution. Universities and medical schools which provide the country with physicians and investigators have felt the pressure of declining endowment funds and are looking for new sources of support not only for research but for general administrative purposes. A recent survey of twenty-eight university medical schools, it was stated, showed one-fourth of them to have no money for research from any source. One obvious conclusion drawn from this was that the federal government should give support to these institutions not in the form of specific grants for specific purposes but in the form of general funds to be used by the medical schools as decided by their administrations.

The serious problem of shortage of personnel and facilities in an expanding program was analyzed, and effects of the unwise policy of neglecting the training of scientific personnel during the war was noted. In 1940 there were graduated as Ph.D's 21 in anatomy, 59 in bacteriology, 130 in biochemistry, 70 in physiology and 112 in zoology. In 1945 graduates in these fields decreased to 4, 27, 83, 25 and 27, respectively. Competition for medical investigators from industry and government is a serious and continuous threat, constituting a sort of interuniversity cannibalism. The crisis in the medical schools is attributed by the report to the mounting cost of operation and lack of an adequate program to cope with these problems. Schools are required to increase the teaching load, to increase student fees and to diminish space for research.

The report deals with the organization and administration of government-supported medical research, pointing out the necessity for preventing duplication of effort among the several agencies of the government that support research. In order to avoid such duplication it was recommended that a subcommittee of the Interdepartmental Committee on Scientific Research and Development be established for medical research, composed of representatives of federal agencies and research scientists from outside government. These representatives should be chosen from among professional research workers who are informed on research and its problems and on the requirements of fundamental research, applied research and development. This should apply equally to clinical research, psychologic and sociologic investigation and laboratory work.

Attention is called to the several advantages offered by the government to research workers who are federal employees, i.e., job security, vacations and sick leave with pay, increases in pay and well established retirement benefits.

---

[1] Guzman Barron, E. S.: The Nation's Medical Research, Bull. Atomic Scientists 4:59-60 (Feb.) 1948.

Medical research projects supported in outside institutions by federal agencies are devoted to problems defined by the supporting agencies or chosen by individual investigators and supported by the National Institute of Health or the Office of Naval Research. In the latter cases, outside experts analyze the projects and advise approval or rejection.

The close correlation between the institutions represented on the study sections of the National Institute of Health and the location of approved projects was noted. More than one fourth of the five hundred and forty medical research projects supported by federal agencies in outside institutions during the fiscal year of 1947 were located in seven medical schools in the northern and eastern parts of the country. " Unless a conscientious effort is made to spread some of the available project money among little known institutions, there is little likelihood of expanding the number of medical research centers and capitalizing fully on the potential of research manpower."

The major question in the problem of improving medical research throughout the country is that of fellowships, postdoctorate and predoctorate. A number of organizations give the former type, but only the National Institute of Health subsidizes graduate students interested in becoming research scientists. In a plan to deal with the nationwide shortage of medical scientists the report lists these recommendations: *(a)* triple the number of fellowships in medical and allied sciences; *(b)* increase the fellowships' stipend; *(c)* give special emphasis to areas of shortage, *(d)* put the task of selecting and alloting funds for fellowships in the hands of persons responsive to both executive and legislative controls; *(e)* give careful consideration to the need for undergraduate scholarships in the basic sciences related to medicine; *(f)* make the whole program of the federal government flexible enough to allow shifts in emphasis between research fellowships and project research as needed, and *(g)* give encouragement to fellows to return to their original institutions with the hope of developing subsidiary research and training centers.

In most respects the report is well conceived and the recommendations, if carried out, would help to expand and improve medical research in the United States. However, much additional stress should be placed on medical research from the personal point of view. The concept of the starving scientist so devoted to his work and to the benefit of humanity that he can afford completely to neglect monetary considerations has become a part of the accepted pattern in this field; sufficient consideration has not been given to it as one of the major problems of obtaining research personnel. Many brilliant and promising young scientists have through force of economic circumstances and disgust with the paltry income associated with research given up research to enter more lucrative fields. The maximum fellowship stipend now offered by the National Institute of Health is $3,000 per year for a person with dependents. Research and teaching fellowships in universities average less than $4,000 per year. These sums attract few men of the caliber needed to improve and expand medical research in the United States. Medical research in industry and in government services has been chiefly of the applied or developmental type. The first inclination of sponsors has been to support research that would soon prove useful or adaptable clinically. More recently, however, a shift toward research in cancer and some of the more recalcitrant, degenerative diseases represents a triumph of scientific curiosity over utilitarianism. In the basic sciences, anatomy, physiology, embryology, bacteriology and genetics, tall towers of knowledge have been erected. In few instances, however, can we fit our basic knowledge in these spheres to the simple logic of figures or formulas, the measure of a true science.

With the funds hopefully forthcoming, increased numbers of well paid, trained scientists should make rapid strides in the basic sciences. Team methods developed during World War II give much promise and should overcome many of the deficiencies of the individual approach.

SCURVY AND RICKETS ARE STILL WITH US

The clinical application of fundamental principles of nutrition is not abreast of increasing knowledge of nutrition. Infants with rickets or scurvy still appear frequently in the pediatric clinics of many of our teaching institutions. Recently a relatively small pediatric service admitted 3 infants with frank scurvy in as many months. The gratitude of the teaching staffs for such teaching material is exceeded only by the embarrassment of rationalizing the occurrence of such cases to the medical student. From his earliest days in medical school, the modern student has been taught that prophylactic administration of vitamins C and D should reduce scurvy and rickets to obsolescence.

Association of scurvy with poverty, malnutrition and lack of medical care is no longer entirely valid. Many recent cases have arisen in families of moderate economic circumstances and have demonstrated optimal gains in length and weight. Usually patients have been observed at regular intervals by physicians. Factors other than parental ignorance or economic circumstance must be at fault.

Almost uniformly these infants have been fed on proprietary preparations which are often represented as "complete infant foods." Indeed, the rapid gains in length and weight testify to the completeness of these foods—with the exception of vitamins. Because growth is occurring rapidly during infancy, requirements for vitamins must be fully satisfied; growth will cease if these demands are not met. As these preparations are usually fed under the direction of a physician, he must assume the responsibility of ascertaining specifically the vitamin content of these preparations in relation to the specific needs of the patient, regardless of the claims of the manufacturer concerning the completeness of the food. Reliance on such preparations for appropriate intake of vitamins is unwise since quantities of the product fed from day to day and from patient to patient are highly variable. Oliver Wendell Holmes said, " A pair of substantial mammary glands have the advantage over the two hemispheres of the most learned professor's brain in the art of compounding a nutritive fluid for infants." Perhaps in these days when hypofunction of the postpartum breast is a national phenomenon, refuge in the cerebral hemispheres of the learned physician is necessary. Fortified with adequate knowledge of nutrition, he can eliminate scurvy and rickets from the American scene.

Current Comment

VITAMINS OF THE " B " COMPLEX AND RESISTANCE TO MALARIA

The effect of a vitamin deficiency on resistance to infection appears to be dependent on the relative requirements of the infectious agent and of the host for the particular vitamin. If the invading organism requires larger amounts of the vitamin than the host, deficiency of the vitamin appears to increase the resistance to the infection; if, however, the host requires the larger amount of the vitamin, deficiency decreases the host's resistance. Increased resistance to malarial infection is found in deficiencies of both riboflavin and pantothenic acid in chickens and in lack of ascorbic acid in monkeys. Deficiencies may be produced not only by low levels of the vitamins in the diets but also by the administration of analogous compounds which antagonize the vitamins; one of these compounds, pantoyltauramido-4-chlorobenzene, has been found to be four times as effective as quinine in the treatment of a standard four day trophozoite-induced infection.[1] This analogue of pantothenic acid inhibits only the blood phases of the infection; either the tissue phases apparently do not require pantothenic acid or there is a sufficient small amount in the tissues. Deficiency of other vitamins, such as nicotinic acid and biotin, is accompanied by a definite decrease in resistance to the malarial organism. The cause of the diminished resistance in biotin deficiency has been investigated and found to be due to decreased formation of an active antimalarial factor, lipid in nature and associated with the serum proteins.[2] Injection of plasma protein fractions rich in this factor inhibit the multiplication of the malarial parasite. This substance, which is formed only when the diet contains biotin, will replace biotin on a biotin-deficient diet, although it does not have the chemical properties of biotin. Further studies on the nature and properties of this anti-infective agent will be awaited with interest.

THE PROGRAM OF THE NATIONAL CANCER INSTITUTE

The functions of the federal government in research and control of cancer were outlined in the National Cancer Institute Act of 1937, which created the National Cancer Institute and the National Advisory Cancer Council. In July 1947 the National Cancer Institute was reorganized to provide for effective integration of a much expanded program.[1] The activities of the institute were divided into three major fields: scientific research within the institute, research grants to outside institutions and cancer control. The institute's total appropriation for the fiscal year 1948 is $14,000,000. Some of the technics employed in the study of cancer by the biology section are artificial production of cancer in experimental animals; study of tumors grown within a transparent chamber attached to the living animal, and growth of animal tissue in vitro. This section is also engaged in establishing procedures for the isolation of tumor-inducing viruses. Grants have been awarded for the work of one hundred and ninety-two different investigators in eighty-eight institutions, mostly universities or hospitals with research laboratories. The institute also awards research fellowships to increase the number of trained scientists from whose ranks men and women may be recruited to staff the laboratories in which research on cancer is conducted. There were one hundred and nine research fellows on duty Jan. 1, 1948. The program recognizes that the key figure in cancer control is the physician. Every effort is being made to provide the members of the medical profession with opportunities for training in the diagnosis and treatment of the disease. A grant-in-aid program has been undertaken to enable medical schools to develop better integrated courses in cancer for their students. Grants to forty schools, amounting to approximately $900,000, had been recommended up to Jan. 1, 1948.

ORGANIZATION SECTION

NATIONAL CONFERENCE ON RURAL HEALTH

Third Annual Meeting, Palmer House
Feb. 6 and 7, 1948

(Continued from page 777,
THE JOURNAL, MARCH 13, 1948)

Dr. F. S. Crockett, Presiding

Rural Public Health Organization

Panel Discussion

MRS. GLADYS TALBOTT EDWARDS, Director of Education, Farmers Educational and Cooperative Union of America, Denver: The National Health Program of the American Medical Association states that every child should have proper attention, including scientific nutrition, immunization and other services included in infant welfare. No one would disagree with that statement, and many believe that every child should have more than this in health care. They feel that health is a public responsibility just as education is. This must be true for the Negro child in rural areas as well as for the white child in rural areas. It has too long been taken for granted that farmers are healthy because they have plenty of fresh air and sunshine. We have closed our eyes to the fact that poor housing, poor ventilation, poor nutrition, contaminated water and milk supply and a lack of insect and rodent control can almost completely offset the fresh air and sunshine.

At a recent health workshop held in Aberdeen, S. D., about two hundred farm people gathered to discuss their health needs. Under the heading of public health needs were listed five major items: (1) a need for district public health units and facilities; (2) better nutrition including a high school lunch program; (3) better housing; (4) a safety program for accident prevention, and (5) an over-all recreational program. It was taken for granted that the public health service would supply the following: prevention and control of communicable diseases by immunization; x-rays; tuberculosis and venereal disease and cancer control; maternal and infant care clinic, and a program in sanitation. These needs were listed by farm people. No experts from the government helped to list these needs. The people knew the lack of a public health program from bitter experience. Extending public health care to rural America is one of the most important tasks before us today. With public health care must go a program of education and preventive medicine, some plan for paying the cost of illness and accidents to farm people.

DR. FLORENCE R. SABIN, Chairman, Interim Board of Health, Denver: In Colorado there are sixty-three counties, eighteen of which have preventive medical services. The eighteen counties include those with large cities, so that one half of the population is really covered with preventive medicine. The rural areas still need to have basic health services set up, the fundamental things, the things that have to be proved over and over again to be of real value to the people.

I want to stress the basic services that should be given to the people of rural America. There are six of them well known to everyone working in public health.

First, the control of communicable diseases: We still have 150 cases of diphtheria per year in Denver. Diphtheria is an outstanding example of the diseases which can be controlled. Our school children are protected. It is the preschool child who is not protected in a backward state. Second, environmental sanitation: Each county, each district, each group of counties needs to have good sanitary inspection. We have just begun these services in Denver. It is an educational program to teach persons in occupations that affect the health of their neighbors how to work in an expert manner and, from the standpoint of health, in a clean manner.

The program is difficult because it involves training adults to break habits that are bad. When you set up your services, don't expect your health officers to do this difficult job in a short time.

Third, laboratory services: Every health department needs the division of laboratory services. It is especially important to get adequate laboratory services on the western slope. Colorado is divided by the Continental Divide, and by the time one gets materials and reports back from the state laboratory it is sometimes too late. It is essential for us and probably for other states to have well developed laboratories scattered through the state.

Fourth, vital statistics, keeping adequate birth and death records. Fifth, the division of hygiene, maternity, infancy and childhood: It is vitally essential that this group have the most adequate health preventive services. There are special rural problems that I want to stress. First, this problem of animal diseases, for instance, brucellosis. A survey in Michigan showed that each cow infected with Bang's disease produced about 2,000 pounds less milk per year than a normal cow, and it was estimated from the number of diseased cows in Michigan that there was a loss of 222,000,000 pounds of milk per year.

Our loss in Colorado on the same basis is 37,000,000 pounds of milk per year. The figures for the United States must go into the billions. What might that milk mean to the welfare of the world?

The next rural problem is rodent control. We have now in Colorado an expert who, for the first time in all history, cleared out the rats for our stock show, a big event in Colorado. Not a rat was there. We know how to do it.

Rural Dental Health Problems

Dr. LON W. MORREY, Editor, Journal of the American Dental Association, Chicago: At least 95 per cent of the American people suffer from some form of oral infection. Studies indicate that American children between 6 and 18 years of age require about 244,000,000 fillings to place their mouths in a healthy condition and that once this backlog of accumulated need is met dentists would have to insert an additional 33,000,000 fillings per year to fill the annual increment of cavities in that age group. Cavities develop in children's teeth at a constant rate, 1 carious tooth every sixteen months, or three quarters of a tooth per year. Among adults there is an average need for 4.5 fillings and more than two extractions. About 1 of every 4 adults needs one or more bridges, while 1 of every 6 requires full dentures.

The few studies that have been conducted to show the relative incidence of dental disease in rural and urban areas indicate that there is little difference between urban and rural dwellers as far as the incidence and prevalence of dental caries is concerned. This is not surprising, as both groups are exposed equally to the conditions that cause dental caries. Most research workers agree that decay of the teeth is caused by the overconsumption of carbohydrate foods, particularly sugars. City and farm dwellers set essentially the same table, and both consume a larger quantity of sugar than in previous years. There is little likelihood that the American people will reduce their consumption of carbohydrates, even though they know that caries will result. Until some simple measure is discovered that will counteract the caries-producing effect of sugar both urban and rural dwellers must resign themselves to the discomfort and dangers of dental disease or avail themselves of early and regular dental care.

The unequal distribution of dentists in Illinois is typical of a condition that exists in most states. A study made by the Committee on Economics of the American Dental Association showed 6,116 dentists licensed to practice in Illinois, or approximately 1 dentist to 1,300 persons. The distribution of dentists in this state, however, is decidedly uneven. The Chicago metropolitan area has over 9 dentists per ten thousand population, while the southern section of the state has but 3.5 dentists for the same number of persons. This uneven distribution of dentists exists in practically every state. There is strong tendency for recent dental graduates to return to their home communities to practice. Since the majority of dental students come from metropolitan areas, the majority of dentists locate in those areas, with the result that some cities have more dentists than are needed and many rural areas have too few. For some unknown reason, few rural students are attracted to dentistry.

Between 1930 and 1944, dentistry graduated about 1,700 students annually and the profession lost about 2,200 dentists per year through death and retirement. During the two years since 1945 dental schools in the United States have graduated about 2,600 dentists per year, and there is every prospect that our forty schools will be filled to capacity for several years to come. However, even though dentistry is able in the future to graduate 2,600 dentists per year, this number is not sufficient to replace those lost annually and to take care of the increasing demands for dental service. Furthermore, the slight increase in the number of dental graduates for the past two years is not in proportion to the increase in the population.

The American Dental Association fully recognizes the problems involved in improving the dental health of the American people, and the association is attempting to meet those problems by encouraging: (1) dental research; (2) educational programs that will motivate persons to avail themselves of early and regular dental attention so that they may avoid expensive restorative service, and (3) dental service programs for those who cannot provide service for themselves, particularly service programs for children, as dentistry for children is the best method known to control dental caries. The dental association is attempting, through its state and local societies, to encourage more qualified young men and women from rural areas to enter the profession. Until our dental educational facilities are expanded the number of dental graduates each year will be inadequate to meet dental demands. The association is encouraging the establishment of additional dental schools. There are prospects that two, or possibly three, new schools will be established in the near future; even so, the additional number of graduates will in all likelihood be insufficient. Therefore, the association recommends the employment of more qualified ancillary personnel. It is encouraging the expansion of educational facilities for the dental hygienist and the dental technician, and it is encouraging the employment of more dental assistants.

Finally, the American Dental Association, through its Council on Dental Health, is encouraging the establishment of state and local councils on dental health. These councils, composed of representatives of dental, medical, educational, civic and other lay groups, are stimulated to study local dental health problems to analyze needs and then develop a practical community dental health program. Representatives of farm groups should become active members of the local dental health council. No one dental health program for the United States will ever be satisfactory. Each community, whether it be rural or urban, must understand its own problem; recognize its own needs; evaluate its personnel, facilities and funds, and determine its own desire to improve its own dental health. Even though the obstacles may seem insurmountable, most communities, armed with these facts and motivated with a determination to reduce dental disease, can develop a dental health program which, even if not adequate, will be a decided improvement over the one that now exists.

Discussion

DR. ETHNA B. WINSTON, South Carolina State College, Orangeburg, S. C.: Is there any arrangement whereby a cooperative plan may be provided for the training of persons to do the health services, whatever they may be, other than or in addition to physicians and dentists, particularly in the rural areas.

DR. CROCKETT: That is an interesting question, and something must be done. Just how it should be done is beyond my experience.

DR. FLORENCE SABIN, Denver: The facilities for training persons in public health are meager anywhere, except in the eight or nine basic schools. We have no school in the Rocky Mountain area for training public health workers. We hope to establish one. The medical school has a course for undergraduates in medicine in public health, and Negroes are admitted to our medical school.

DR. A. W. BROWNING, Elloree, S. C.: It has been said that doctors down south do not treat the Negroes. One half of my work is with Negroes. I believe it was last year or two years ago that I drove 7 miles in a buggy and 2 miles on dirt road to a Negro house to give treatment. In our section we don't refuse treatment. I just didn't want anybody to say we didn't treat them.

J. S. JONES, St. Paul, Minnesota: Dr. Sabin elaborated on brucellosis as an economic scourge to the animal industry. Would you please elaborate on the parallel cause of undulant fever to human beings?

DR. FLORENCE SABIN, Denver: Dr. Stiles, who has now come into the Colorado state department of health, is trying to get accurate data on the amount of human infection. It is a difficult task. Accurate data is obtained by making the agglutination test and getting the history of every single patient as to whether he had any vaccination or not. As far as the skin test is concerned, Dr. Darling, who is here at this conference, made an estimate that about 15 per cent of the inhabitants in Colorado have a positive skin test. Of course, that doesn't indicate the amount of infection. Those of us in public health believe that the amount of true infection is greater than is commonly recognized. We still await accurate data.

MRS. JEROME EVANSON, Jamestown, N. C.: Dr. Sabin, how do you get personnel for your public health district units? In North Dakota we are ready to move out in district units in every county in our state, but we are told we cannot get personnel. One more question. When we cannot get the full time service of a public health physician for our district, would you recommend that we take the part time services of local physicians?

DR. FLORENCE SABIN, Denver: I am convinced from the little that I have seen, and I am only a novice in this public health work, that specific training in public health is tremendously important. That was why I stressed the big educational problem. I believe that training in public health teaches the worker how to get people to cooperate. It is really a matter of expert education.

DR. BEAUDRY, Montreal, Canada: Emphasis has rightly been placed, since the beginning of this conference, on preventive medicine. But I would like to dwell on the problem of tuberculosis. In the United States the mortality rate has been reduced to 35 for hundred thousand population, and if the trend keeps on going for a few years more, it is thought the mortality will come down to 15. This is wonderful work, but what about the lives which are still lost through tuberculosis? The answer is simple, because we have BCG vaccine for use against tuberculosis. This has proved of value in contaminated families. A doctor in Montreal and a doctor in Saskatchewan have obtained 70 per cent reduction in infected families where the children have been given the vaccine at birth. This has been done while the children were not separated from the infected patients, but when this separation is made, as we have done in close to 1,000 newborn children in Montreal, the reduction has been close to 100 per cent. Vaccines are being studied at present in this country by the U. S. Public Health service. We hope that the United States will come in line with other countries which give the opportunity to all physicians to use the vaccine.

DR. M. P. NEIL, Columbia, Mo.; I cannot allow the question of undulant fever to go unchallenged. I am sure Dr. Sabin will agree that the skin test is no more diagnostic of brucellosis than a skin test is diagnostic of tuberculosis. I am sure all who are familiar with the disease agree that the agglutination test is not a conclusive diagnosis of undulant fever. There is one absolute diagnosis, and that is recovering the organism from the blood.

DR. FLORENCE SABIN, Denver: I agree, and it is well known that a patient or an animal may have a negative agglutination test, and the next day the organism may be recovered from the blood. We should go on and eliminate this disease from the animals that are the source of the infection.

DR. D. G. MILLER JR., Morgantown, Ky.: During the war when the state health department in Kentucky was weighed down with selective service examinations, there was an incidence of brucellosis of about 5 per cent positive agglutination. Another problem that must be contended with is means to stop transportation of the infected cows over the state line. I know of 25 or 30 cows that have been brought into Illinois and sold from my own county in Kentucky because the owners could sell them as high grade milk cows in Illinois but didn't dare try to do that in Kentucky. They have taken animals to Alabama, Missouri and Tennessee in that area. I further know that these small milk producers go to the stockyards and buy these cattle and start putting the milk in the pool which they offer for sale without testing. When the veterinarian catches them, they take the cow out. That cow's milk may be sold for weeks before the cow is tested for brucellosis or tuberculosis. That is one phase of the problem for which we are going to ask for help. I am opposed to federal aid, but this is one time when we should have it.

MISS JUNICE DALEN, Willmar, Minn.: I would like to know if the American Medical Association is in favor of having these public health units set up on a county basis or a multicounty basis, and second, if so, are we to understand that they will give active support for legislation which will help us get the public health service? We had a bill introduced in the last session of the legislature which was defeated, and we are going to introduce it again at the next session.

DR. CROCKETT: The American Medical Association was among the first a hundred years ago to champion public health and the creation of a public health service, and they have consistently championed that idea. The American Medical Association speaks merely on a national level. It does not go into any state and tell a state group of physicians what they must do. It does stand for the very best in public health service.

J. S. JONES, St. Paul, Minnesota: The state medical society has endorsed the program in Minnesota and is active in promoting it at present. There was some misunderstanding in the last legislature. I would like to mention public health medical personnel and public health institutions for tuberculosis and institutions for the care of the insane. If you want good personnel in these fields, you cannot simply rely on education. You have to change the thinking of our people so that personnel can be employed in those institutions at a level of pay comparable to that of a practicing physician. In the past year, we have had three trainees' funds to pay a physician $300 per month if he would go to school and learn public health. We couldn't get a taker.

DR. FLORENCE SABIN, Denver: In our state medical association we had the full cooperation of our physicians. We had the same experience. Our bill failed one year; the next year we all got together, and the public health people and the medical profession wrote the bills together. We each made some concessions in writing the common bills, which then were presented to the legislature with the backing of the public health services and the physicians who went to the legislature and fought day in and day out just exactly as hard as the public health people. The point is to get cooperation long before your state legislature meets.

We have the same problem with regard to salary in Colorado. We got the salaries in Denver up to fairly adequate levels. It is terribly hard to get the state salaries up. You simply have to educate your total population and get across to the people that it is worth while to spend money for health.

MISS MARGARET STEIN, Washington, D.C.: Dr. Crockett, would the American Medical Association support federal legislation granting funds to the state to provide more public health units and serve the 30,000,000 persons not covered by full time health departments? To my knowledge there is no such legislation. However, it has been recommended occasionally before committees.

DR. CROCKETT: Federal money is available, I believe, to the state public health departments for certain definite purposes. The policy, if it has not been settled by the American Medical Association, would be a matter for action by the House of Delegates. They are the only group within the profession that would be qualified to set a policy.

DR. ROBERT E. ARCHIBALD, Melrose, Mass.: I have a few copies of a proposed bill that it is hoped will be introduced in Congress this year to get an appropriation to be used entirely for the development of local health units and the training of personnel.

Olmsted County Child Health Project

DR. FLOYD FELDMAN, Director, The Rochester-Olmsted County Health Unit, Rochester, Minn.: The title on the program is misleading, as there is no Olmsted County Child Health Project. There is a Rochester Child Health Institute, which was formerly called the Rochester Child Health Project. This institute has limited its research program to the city of Rochester, but its services reach all parts of Olmsted County.

The Rochester Child Health project began operations in January 1944. It has two purposes, research and service to the children of Rochester. This project, headed by Dr. C. Anderson Aldrich, is attempting to provide the best maternal and child health supervision possible for mothers and their babies born in Rochester. The staff has grown to include an assistant director, psychiatrist, two psychologists, nutritionist, director of preschool activities and a statistician.

The Child Health Institute plans to carry its observations and supervision from the prenatal period to adult life on every baby born in Rochester. The city health department, the city public schools, the county board of commissioners, the state board of health, the W. K. Kellogg Foundation and the Rochester Child Health Institute all contribute funds and services. To bring them together, the Rochester-Olmsted County Health Unit was formed, with an administrative council and an advisory committee. The health unit is not an official governmental entity but a voluntary group, without funds of its own, for the sole purpose of coordination. The city health officer is permanent chairman of the administrative council.

Three half-day prenatal clinics are conducted each week at the Rochester City Hall for rural and city patients. The clinics are conducted by fellowship physicians from the Mayo Clinic. During 1947, 114 patients from the city and 127 from the rural area attended these clinics. In the same year there were 708 births in the city and 506 in the rural part of Olmsted County. The public health nurses made 1,125 home visits to these women last year before their babies arrived.

At the time of delivery in the hospital, a record is started which is expected to follow the child to maturity. The mother is instructed in the care of her baby and what she can expect in the way of normal behavior and development. Every effort is made to encourage breast feeding.

For children born at home under the care of the few private practicing physicians, and 13.6 per cent of the rural resident babies are born at home, this period of training and instruction must necessarily be more limited. When the baby and mother are ready to go home, the hospital notifies the public health nursing service, and a home call is made immediately to get the mother started on her routine. Subsequent home calls are made when necessary, but most supervision is carried on through the child health clinics. These clinics are closely supervised. The rural clinics are held at different centers at such intervals as to provide a monthly clinic to any one area. The same physicians work in both rural and city clinics, although only the city children belong to the institute research group. Mothers are encouraged to bring babies in once each month for the first year, then every two months until 18 months of age, every three months until 2 years of age, then every six months until school age. Immunizations are started at 6 months of age for whooping cough, smallpox, diphtheria and tetanus. Under the direction of the Child Health Institute, a local lay board conducts several nursery schools for the preschool children who need such experience. There are not enough preschool classes to meet the need, but more are being organized. Unfortunately, none of these are operating in rural areas, where they are probably as much needed as in the city.

The Rochester Child Health Institute furnishes many services in the school health program. In the city, physical examinations are given to all entering children, all those referred by nurses and teachers, and those in the fifth, ninth and twelfth grades. These examinations are preceded by teacher-nurse conferences, vision tests, height and weight measurements and planning conferences. Although no free medical care is given through the schools, most of the significant deviations from the normal are taken care of through the parents' private initiative and funds or with the help of welfare agencies and service clubs.

An immunization program for smallpox, diphtheria and protection against tetanus is offered in the schools each year for additional protection of those given inoculations in infancy.

The dental program has as its aim the annual examination by a private dentist of every child over 3 years of age. Cards are given to the school children to be signed by the dentist and returned. Results vary from 100 per cent in some schools to few or none in others. Reasons for low percentages in certain schools are now being investigated.

A special roster of crippled children is maintained so that no child will be neglected, and the many orthopedic services available here have been fully used. A complete register of tuberculosis cases and contacts is maintained. Roentgenologic and tuberculin tests are offered at little or no cost. The county, with seven others, maintains an excellent sanatorium which has enough beds for all active cases. A counseling clinic for those of all ages with a psychiatrist in charge has been operating now for seventeen months. The city restaurants are regularly inspected and utensils cultured. A survey completed recently gave our eating and drinking establishments an average rating of 72 per cent, according to the code of the U. S. Public Health Service. Rural milk supplies, water supplies, rural eating and drinking places and the rural schools have had little sanitation service, and the need is great. In 1947, the expenditures for these were as follows:

Rochester Board of Public Health and Welfare	$38,618.51
Rochester City Schools	$12,108.22
Olmsted County Board of Commissioners	$ 6,093.94
Minnesota Department of Health	$ 7,620.14
University of Minnesota	$ 1,424.75
W. K. Kellogg Foundation	$18,716.65
Mayo Clinic	$ 1,674.18
	$86,256.39

This amounts to $1.66 per capita, not counting the services furnished by the Mayo Clinic and the Rochester Child Health Institute. As judged by a maternal mortality rate of 0 per thousand births and an infant mortality rate of 17.3 per thousand births, we can look forward to greater reductions in morbidity as well. One of our greatest hopes is that a modern approach to health supervision of the child will materially lessen the numbers of poorly adjusted children with a consequent decrease in child delinquency and adult mental disease.

Rural Youth Looks at Health

MR. EDWARD H. MERTZ, Executive Secretary, Farmers Educational Foundation, Denver: For the first time in this series of health conferences we have brought in with us the farm young people. My colleagues in this panel represent the American Farm Bureau Federation, the

National Grange, the National Milk Producers Association and the National Farmers' Union. These farm organizations are members of the Rural Medical Service Advisory Committee of the American Medical Association.

These farm organizations propose various programs to provide better health services for rural people. We are not confined in our thinking to the organizations which we represent or to the areas represented by members of this panel. We are talking about the problems of the 6,000,000 farmers in America and the 30,000,000 persons who make up these families. We know that 40 per cent of the wives of farmers of low income have neglected childbirth injuries; 10 per cent of their children are seriously underweight, 48 per cent have defective tonsils and 65 per cent have decayed teeth; 14 per cent of all farm mothers have no hospital care when the babies are born. We know that regardless of what you call the process, over half of the young men from farm homes were rejected by selective service. As citizens representing farm youth, we have a responsibility to build a strong America. We shall try during this panel to analyze the causes of this unhealthy rural America and explore the way that persons in rural areas might provide themselves with adequate health services.

The first presentation of this panel will introduce the general problem, and the second and third presentations will give you a background of what farm organizations are doing, and the final presentation will give you a picture in terms of program and philosophy of what rural residents think that we should be doing.

It was difficult to arrange this panel in the strict sense of the word as these folks live in four states and, unfortunately, I live in another one. Arrangements were made by correspondence up until 11 o'clock last night.

MISS RUTH PARSONS, Chairman, National Rural Youth Committee, American Farm Bureau Federation, Fowlerville, Mich: Rural health is not just a problem of the American Medical Association. It is the problem of everyone, and as soon as everyone becomes aware of that, something will be done about it. With lay persons assuming more of the responsibility in getting these facilities for improvement of rural health there may be some difficulty in understanding the way that it should be brought about. The farmer has a most intricate profession, one that requires ablebodied and mentally alert workers. The best crop raised on the farm is the children. One hundred thousand persons in a certain city in one generation failed to reproduce themselves by 33 per cent; yet the cities are growing larger. Where are the people coming from? The urban areas are failing to reproduce themselves by 26 per cent and the rural areas are overproducing by 44 per cent. We figured out the health problems, which the rural residents classified in four groups: (1) nutrition; (2) poor health education; (3) lack of health units and hospitals, and (4) that rapidly decreasing person, the general practitioner. Unless the farmer's wife knows why her family should have vegetables and fruits and which ones and how often, those on the farms are going to eat what they do now: meat, potatoes and sweets. She has to know how to pick foods that have the highest food value. There is a serious lack of community health services. Two fifths of the counties are without a full time health department. In our community they are trying to get one started. Only three fifths of the counties have registered hospitals, and most of the hospitals are concentrated in the urban areas. Those in rural areas are not equipped as they should be. Michigan pioneered, I believe, a great deal of the work in both the medical groups and the farm bureau in getting the Blue Cross Hospital Plan. The farm bureau in that state offers all members drastically reduced prices, and this is doing a good deal to improve conditions. The Hill-Burton Act will increase the amount of hospitals in the rural area. One would think that in view of those facts there would be more physicians in the rural counties. Only one of a graduating class of young physicians is going to settle in a rural area. Is it the fault of the medical schools? Do they advocate specialization? Is it the fault of the physician? I don't know whose fault it is, but it is something that will have to be changed. I was going to tell you what the Junior Farm Bureau does. It is made up of representatives of the midwest section, who have worked for community health centers. One county has started the groundwork for a hospital. Most of the counties do similar things. They work in their own area rather than on a statewide basis. I hope that this is not just a discussion, but that a great force for the improvement of rural health will come out of it.

MISS MARTHA KOHL, Secretary, Genesee County Chapter, Dairymen's League, Corfu, N. Y.: There was a time when living in the country was considered especially healthful and was presumably the best way to raise children. But one fourth more rural babies than urban infants die in their first year. The rural child runs a greater danger than the urban child of dying from measles, scarlet fever, whooping cough and other diseases frequent in childhood, which modern medicine is quite successful in preventing. Perhaps the rural people should accept the blame for these conditions. We have never provided a plan to make preventive and curative medicine readily available to everyone. We have left pretty much to chance the distribution of doctors, dentists and nurses. We have left to the doctors the entire responsibility for providing their own equipment. Often we have left even the building of hospitals to the medical profession. Forty per cent of the 3,070 counties in this country have no hospital worthy of the name. The cities average a physician for every seven hundred persons, while rural communities average one for seventeen hundred persons.

But statistical averages do not tell the whole story. They mean little to the residents of Dubois, Wyo., who are 78 miles from a doctor. In 1944 every ablebodied physician in Taos County, N. Mex., had 6,134 potential patients, as shown by a check of the Farm Security Administration. Such conditions can be corrected through the Federal Hospital Survey and Construction Act if the rural people accept the responsibility and make the most of this opportunity. The lack of sanitation facilities presents a problem. Recently, the entire supply of drinking water in a neighboring village was found to be contaminated. Authorities believed that the improper disposal of sewage was the cause of the trouble. A program to inform rural people of the importance of this problem is necessary as the population of these areas is constantly increasing.

Accidents on the farm take the lives of many persons. Machines have become a menace to the well-being of the farm family. Other industries are required by law to provide safety devices and to compensate those injured, but little has been done to prevent accidents from use of farm machinery. In addition to the national and state safety programs there is a need for community organization to fight carelessness. The New York State Grange has recognized the need, and lecturers devote a part of each meeting to safety. A new film on farm safety, "Miracle in Paradise Valley," will be shown this coming year before all the granges and is available for other groups.

A column devoted to rural health in the monthly *Program Letter* to women of the Dairymen's League brings them information of all kinds. Essay contests in schools, play writing, menu contests and exhibits for meetings, fairs and field days are a few of the activities which include the youth in our health education program. The need of producing clean milk was taught through plays, movies, discussions and speeches at community meetings.

The New York State 4-H Clubs have for several years been guided in their health program by a committee made up of club agents, specialists and members of the 4-H administrative staff, with representatives of the various state departments and other organizations.

The objectives of the 4-H Health Improvement Project as set up by this committee are: (1) to encourage the correction of remediable defects; (2) to help young persons to develop sound bodies and mature personalities; (3) to encourage the acquirement of knowledge, skills and good habits related to health and safety; (4) to help youth share the responsibility for improving home and community health conditions, and (5) to help 4-H members and leaders to develop the goal, "Building Health for a Strong America." Many club programs included individual improvement in health, assistance in poliomyelitis drives, a drive to get every member to have roentgen examination of his chest, health exhibits, milk sanitation, fire prevention, vaccination clinics, first aid training, farm safety, and nutrition and food preparation projects.

The farm youth of America will accept their part in the health and safety programs.

MISS BETTY CHANDLER, Youth Committee, Farmers Educational and cooperative Union of America, Jamestown, N.D.: I would like to speak for those of us who want to live on the farm because to us there is no more satisfactory way of living. I would like to speak particularly for the Great Plains area. In the more heavily populated sections the problem is not so much lack of services as inability to pay for needed services. Both these major problems confront us in the Great Plains states, where the population is sparse and the distances are great. Our income is subject to great variation because of weather and crop conditions.

How does this affect our health problems? Here are some facts from my state. Twenty one of fifty three counties do not have a hospital. In many of those counties one must travel 50 to 100 miles to a hospital over gravel roads, impassable most of the winter. When the last survey was made, 67 per cent of the people lived in areas where the number of doctors is much less than the minimum standard of one doctor to 1,500 persons. Eighty-five per cent of our people are not covered by public health services, and in our entire state there is only one public health district functioning to provide preventive care to those who dwell outside of a big town. When crops are not good and prices are low we cannot afford medical care, and it is postponed until our illnesses are really serious. Statistics usually show averages and do not point out the great discrepancies of the kind I have tried to show that exist in North Dakota. The farmers' unions and rural organizations are deeply concerned about this situation; our program follows also a threefold pattern in the field of education. Farmers are meeting to discuss the over-all health situation and to study the need of their communities. They discuss information booklets to make them health conscious. The main emphasis in this education work is on the active participation of all persons in health programs. The Farmers' Union has held health meetings and workshops. At these workshops we try to make people aware of what facilities they have available to them. We also want to give them an opportunity to discuss their community health needs and to plan together to meet those needs. It is thrilling to see persons without specialized training in health study their problems at these workshops and become articulate in developing an activation program to meet their needs.

We have encouraged the development of community cooperative hospitals, clinics and prepaid insurance. We have one Farmers' Union insurance plan that offers hospital benefits and accident and death benefits, and this past year we aided in making insurance provisions to cover the cost of surgery as well. The Farmers' Union is working for a national insurance plan because, while we cannot overlook the valuable pioneering work done by the voluntary prepayment plans, they cannot cover all the persons who need medical care. We have seen the miracles of modern medicine as it faced the challenge of global war, and we seek to combine the best of these experiences in a rural health program. We are preparing to do some of these things in rural areas in the great plains. We need more hospitals in most rural areas and we can plan them for the places where they will serve the greatest need. In our rural hospital building program, we are not forgetting to make provision for nursing homes and wings on the hospitals to care for aged persons and chronic invalids.

The State Health Planning Committee in North Dakota with a group of representatives of interested organizations has developed a fine program for building rural hospitals. We need not only more health services but adequate housing, accident prevention, good roads and communication, creative recreation and a more stable income. Any advances we can make in any of these fields is also a gain for health. There is no reason why the barriers confronting rural residents in securing health care should persist, and we intend to work to help remove them. Many rural young people are taking medical and public health training and becoming nurses, hospital administrators and dentists with the desire to return to rural areas to serve. They are counting on those at home to set up clinics, health units and hospitals and to develop a prepayment plan to insure that the people can use the facilities, so they can return to rural areas to work and make their homes. They are counting on the cooperation of everyone in the development of better health services.

ELBERT HUTCHISON, Xenia, Ohio: *Health Facilities and Needs in My Community.* The Grange, the oldest farm organization in America, is most interested in the health of rural people. From our fields and homes come the wealth of America; if we are to continue to contribute so much, we must be ever mindful of the health of rural boys and girls. Some 36,000,000 Americans live in farm or village homes today, with about 89 per cent without bath or inside toilet, 82 per cent without proper water facilities, and 38 per cent with homes in too poor a condition to be repaired. The barometer of human welfare in our farm homes shows unnecessary illnesses, diseases, disabilities and deaths. In most farm communities, public health units are scarce and the supply of hospitals, doctors and nurses is inadequate. The quiet ravages of malnutrition go unchecked, babies are born without the care of a physician, and antepartum care, childbirth in hospitals and good care of the mother and baby are unheard of in many farm homes.

To guard our youth we must devise a method of putting the low paid farmer and sharecropper on a basis to compare with the average of workers in industry.

In cities about 72 per cent of the childbirths are in hospitals, and the mortality rate is very low. Medical neglect among farm mothers is about one-third more prevalent than among city mothers. The National and State Granges are advocating a health program which, if generally adopted, will benefit young persons everywhere. In addition to a State Health Committee, every county and every local Grange has a health committee. This committee encourages health programs in Grange meetings and encourages the setting up of health centers.

In my state there is a rural health organization made up of representatives of farm organizations and others. This committee meets regularly, and representatives from every county in the state attend an annual health meeting in Columbus. A rural health specialist who is a part of the Extension Service of our State Agricultural College assists. Regional meetings are held from time to time. These meetings encourage each community to have a health center with a well organized committee working in colaboration with the physicians and nurses. Their object is to make available to all citizens through educational material the information essential to healthful living. Many people who do not practice health rules are unaware that such rules exist.

In our school we have free roentgen examinations of the chest for all high school juniors and seniors. Money from the sale of tuberculosis stamps made possible the purchase of the x-ray machine. Lectures are given on the effects of alcohol and on personality problems of youth. This health education is fine, but there is not enough of it.

My community is fortunate in having a fine public health set-up. We must increase the income of the small farmer, low wage earner and sharecropper to the extent that he will have an equal opportunity to provide the health needs of his family. We need to cooperate in every respect to bring the health of our people up to high standards. Income alone cannot solve the problem. The people must be educated in a new way of living, and their lives changed until everyone will be on a basis of equality with regard to health. This can be done by cooperative groups supporting mobilized hospital and dental units, and centralized medical units and by the assistance of trained personnel.

MR. IRWIN JOHNSON, District Representative of the 4 H: I am not exactly the district representative, but in the absence of any one from the United States Department of Agriculture or the Extension Service, the people that administer the 4 H program, I have been asked to say a few words. 4 H stands for head, hand, heart and health. Over a period of years they have developed numerous projects, aimed at the improvement of rural living. They have safety contests on the farm, they emphasize nutrition, correct habits of sleep and other things necessary to good health. In 1946 there were 180,044 boys and girls who received health examinations through the program who could not have had them otherwise.

A new health program has been in operation for the past year. It has these broad objectives: the program should be planned on the basis of health needs of young persons for each community; it should be planned to cooperate with the local and state health authorities, and it must attract and appeal to youth. Thirty-seven states took part in it. After hearing these four young speakers today I am sure you are convinced that when they get an idea they want to go ahead with it. There are a million 4-H boys and girls around the country and there are many ways to help them do a more complete and satisfactory job.

MISS ELIZABETH ROBINSON, American Junior Red Cross, Washington, D.C.: The most hopeful thing I have heard at this meeting is the fact that you have put youth itself up here to talk to you. One of the secrets of success in this problem of health, is that we can't wait until the boys and girls grow up. We can't plan for either medical attention or education with complete success unless we let them take their part in the total picture.

(To be continued)

Washington Letter

(From a Special Correspondent)

May 29, 1948.

International Centers for Study of Tropical Diseases

Establishment of international centers for the study of tropical diseases was proposed at the closing meeting of the fourth International Congresses of Tropical Medicine and Malaria. The Pan American Sanitary Bureau with headquarters in Washington was suggested as an informational source for coordination of studies of tropical diseases, especially those affecting persons in the Western hemisphere. Also advocated was a survey of world food deficiencies. It was proposed that the Food and Agriculture Organization and the World Health Organization of the United Nations take immediate steps to investigate and correct human nutritional problems. At the concluding dinner in the Mayflower Hotel, the Laveran prize for research in malaria was presented to Col. Henry E. Shortt, professor of protozoology, University of London, and the Walter Reed Medal to Dr. N. H. Swellengrebel, Amsterdam Institute of Tropical Medicine.

Code of Ethics for Specialists in Mental Disease

Dr. Winfred Overholser, superintendent of St. Elizabeths Hospital, stated in his opening presidential address to the American Psychiatric Association in session here that there is need of a code of ethics for the 5,000 United States specialists in mental disease. Although psychiatrists are bound by the professional code of the American Medical Association, the field of mental disease is not adequately covered by the rules; hence, much unfavorable publicity and sensational misinformation results. Dr. Walter L. Treadway, former chief of the mental health division, U. S. Public Health Service, heads an association committee which is working on an adequate code.

Civilian Defense Plan

The members of the medical profession will play a major part in civilian defense. The Arlington Country, Virginia, Board has approved plans for a comprehensive civil defense program in case of atomic war, the first in the area of the District of Columbia. One job will be to locate everyone with any medical training, including veterinarians, to provide treatment in case of mass casualties.

Dr. Justin K. Fuller to Retire

Dr. Justin K. Fuller will retire next month as medical director, Federal Bureau of Prisons, and medical chief, Maritime Commission's training bureau, Surgeon General Scheele of the Public Health Service has announced. Dr. Fuller will be succeeded by Dr. Stanley E. Krumbiegel at the Bureau of Prisons and Dr. Daniel J. Daley at the Maritime post. Dr. Fuller will become medical consultant to the California Department of Corrections.

GOVERNMENT SERVICES

ARMY

OFFICERS SELECTED FOR SPECIALIZED COURSES

The Surgeon General announces the selection of the following officers for specialized courses in civilian and governmental institutions: Lieut. Col. Charles B. Perkins to be assistant resident in radiology at Massachusetts Memorial Hospital for two years, during which time he will also serve as professor of military science and tactics; Lieut. Col. Warren H. Diessner, training in allergy at the University of Illinois College of Medicine, Chicago, during which time he will serve also as assistant professor of military science and tactics; Major Edward H. Vogel, course in surgery at Tulane University School of Medicine, New Orleans, during which time he will serve as assistant professor of military science and tactics; Lieut. Col. William W. Currence, training in pediatrics at the University of Colorado School of Medicine, Denver; Lieut. Col. Theodore L. Hartridge, residency in otolaryngology at Washington University School of Medicine, St. Louis, during which time he will serve also as professor of military science and tactics.

ARMY INSTALLS ELECTRON MICROSCOPE

The electron microscope recently acquired by the Army made its first public appearance May 17 during the fourth International Congresses of Tropical Medicine and Malaria in Washington, D.C., May 10-18. Some 300 of the 2,000 persons attending the congresses viewed the microscope during open house at the Army Medical Department Research and Graduate School on the grounds of Walter Reed Hospital.

DR. SLOAN APPOINTED CURATOR OF MUSEUM

The Army Institute of Pathology, Washington, D.C., announces the appointment of Dr. Ruell A. Sloan as curator of the Army Medical Museum. Dr. Sloan is a graduate of the University of Rochester School of Medicine and has been on the faculty of Harvard Medical School, the University of Buffalo School of Medicine and St. Louis University School of Medicine. He served five years during the recent war as chief of laboratory services at an Army hospital and later as pathologist and executive officer of the Army Institute of Pathology. On leaving the service he was appointed assistant director of the institute and acting curator of the museum. He is a member of the American Board of Pathologists and president-elect of the Washington Society of Pathologists.

PERSONAL

Joseph R. Wagner, Ph.D., former head of the nutrition research section of Libby, McNeill & Libby, Blue Island, Ill., has joined the staff of the Quartermaster Food and Container Institute for the Armed Forces in Chicago. Dr. Wagner is said to have published numerous papers in the fields of biochemistry and nutrition.

Capt. James L. Hansen, M.C., who reported for duty at the Army Institute of Pathology on April 15, recently returned from the 49th General Hospital, Tokyo, Japan, where he was chief of laboratory service.

PUBLIC HEALTH SERVICE

FULL TIME EMPLOYEES IN STATE HOSPITALS

Personnel shortages in state mental hospitals are less acute now than in war years, but this gain is offset by more overcrowding and higher maintenance costs, according to 1946 figures compiled by the Mental Hygiene Division of the Public Health Service. There were 70,962 full time employees on the rolls of state hospitals at the end of 1946, making a ratio of 6.2 patients per employee. This ratio indicates a continuation of the decrease in the number of patients per employee which began in 1945, and represents a reversal of the upward trend which occurred during the war years. The percentage by which the average daily resident-patient population exceeded normal capacity increased from 12.3 in 1945 to 16.3 in 1947, and the per capita expenditure for maintenance rose from about $387 to $437 in the same period.

The figures are based on the results of the 1946 Census of Patients in Mental Institutions, collected and tabulated by the Bureau of the Census, Department of Commerce.

NEW ENVIRONMENTAL CANCER SECTION

Dr. W.C. Hueper has assumed his duties as chief of the new environmental cancer section of the National Cancer Institute in Bethesda, Md. In its announcement, the U. S. Public Health Service points out that there has been relatively little systematic study of cancer-causing factors in industry. It seems clear that part of the increased incidence of cancer is linked to the growth of industry during the past hundred years and to the dangers of prolonged exposure to certain substances. The recent first step in the environmental cancer control program was a grant to the Roswell Park Memorial Institute in Buffalo for a study of causes of occupational cancer among male patients coming to the institute for treatment. The new program includes the establishment of an occupational research laboratory at Georgetown University Medical School where investigators can study environmental factors in cancer. Dr. Hueper, a native of Germany who came to the United States in 1923, is the author of many publications in this and related fields. At present he is president of the American Society for the Study of Arteriosclerosis.

INFANT MORTALITY RATE DROPS

The infant mortality rate in 1946 was 11.7 per cent less than the rate in 1945, according to figures of the National Office of Vital Statistics. The number of infant deaths which occurred during 1946 was 111,063. The five leading causes of death during infancy were: premature birth; congenital malformations; pneumonia and influenza (combined); injury at birth, and diarrhea, enteritis and ulceration of the intestines (combined); 33.9 per cent of all deaths occurred under 1 day of age, 25.6 per cent during the remainder of the first week and 11.7 per cent during the second, third and fourth weeks. The highest infant mortality rate was 78.2 for New Mexico and the lowest was 27.2 for Utah. All but five states experienced a decrease in their infant mortality rates between 1945 and 1946.

SHARP RISE IN BIRTH RATE

A sharp rise in the birth rate in 1946, the first postwar year, was general throughout the country. Data prepared by the National Office of Vital Statistics of the U.S. Public Health Service indicate a total of 3,288,672 registered live births, an increase of 553,000 over 1945 and 354,000 over 1943. The 1946 final birth rate of 23.3 per thousand population including the armed forces overseas was an increase of 18.9 per cent over the rate (19.6) in 1945. The increase in the 1946 birth rate for the white population was more than twice as large as for the nonwhite. The largest increases were in the North Central and Middle Atlantic states. The 1946 state birth rates ranged from a high of 34.9 per thousand civilian population in New Mexico to a low of 20.6 in Massachusetts. Residents of the Mountain and Southern states generally had the highest birth rates in 1946, residents of the New England and Middle Atlantic states the lowest. This is similar to the pattern for 1945. The demobilization of the armed forces in the latter part of 1945 contributed to the sharp rise in the number of births during the second half of 1946. The rates for the early months of 1946 were at about the same level as those which prevailed during 1945.

MISCELLANEOUS

STAFF TO SUPPLY SCIENTIFIC INFORMATION

Dr. George E. Burch, Henderson professor of medicine, Tulane University School of Medicine, New Orleans, has been appointed to the staff of the scientific office of the Mission on Science and Technology recently established by the State Department as a permanent part of the United States Embassy in London. His appointment is for a period of three months. Other scientists on this staff are Earl A. Evans Jr., Ph.D., chairman, department of biochemistry, University of Chicago; Joseph B. Koepfli, Ph.D., of the California Institute of Technology, and Dr. Warren H. Cole, professor of surgery, University of Illinois School of Medicine, Chicago. The principal duty of the staff is to supply information concerning current developments in science and technology in the United States.

NUCLEAR PARTICLES PRODUCED FOR THE FIRST TIME

Dr. James B. Fisk, director of research, Atomic Energy Commission, Washington, D.C., and Dr. Ernest O. Lawrence, director of the Radiation Laboratory at the University of California, announce that nuclear particles, mesons, heretofore found only in cosmic rays, have been produced artificially for the first time at the Radiation Laboratory in research carried on for the Atomic Energy Commission. The liberation in the laboratory of these cosmic ray particles, one of the major objectives of research for the past decade, is regarded by scientists as the most significant event in fundamental nuclear science since discovery of uranium fission. However, no practical applications, such as fission, are now in sight. Dr. Lawrence said that this development opens up unprecedented opportunities for the understanding of mysterious subnuclear processes. In announcing the new achievement of the latest model of the cyclotron which Dr. Lawrence invented eighteen years ago, he gave full credit to the two men who performed the experiments: Dr. Eugene Gardner, research physicist at the Radiation Laboratory, and Dr. C.M.G. Lattes, a Brazilian scientist who came to Berkeley recently on a Rockefeller Foundation fellowship. Dr. Lawrence said that super atom smashers must be built in order to exploit fully the realms of nuclear knowledge which lie still deeper within the atom.

ADDITIONS TO STAFF OF OFFICE OF EDUCATION

The Office of Education, Federal Security Agency, Washington, D. C., announces the appointment of Dr. Cyrus H. Maxwell, Delmar, N. Y., as chief of administration of School and College Health Services, and of Max Herbert Freeman, Ph.D., Montclair, N. J., as specialist in the Business Education Service of the Division of Vocational Education. Dr. Maxwell was for many years chief of the Bureau of Health Services, New York State Department of Education; previously he was medical supervisor of the public schools of Auburn, N.Y., and engaged in the private practice of medicine. He served during World War II and is president-elect of the American School Health Association. Dr. Freeman was formerly professor of business education and head of the department at New Jersey State Teachers College in Paterson. He is co-author of several teaching manuals.

FELLOWSHIP TRAINING FACILITIES

The U.S. Atomic Energy Commission announces that facilities to train holders of fellowships in biology and medicine will be established in North Carolina, New York, Texas, Colorado, California and Oregon in time for the school year beginning this year. The program of fellowships recently established by the commission also allows fellows to train at other institutions.

One problem in the fellowship training program is the shortage of university faculty members who have the necessary specialized training. The commission therefore is arranging a series of courses for the coming summer to give advanced training to faculty representatives at the participating universities. Summer courses will be held at the University of California, Los Angeles, with Dr. Stafford Warren as director: the Institute of Nuclear Studies, Oak Ridge, Tenn., Dr. William Pollard, director, and the Brookhaven National Laboratory, Long Island, under a director to be appointed. Administration of the fellowship program, including the selection of candidates, will be undertaken for the commission by the National Research Council. Applicants from any branch of biology or medicine are eligible for fellowships which will be distributed among doctors of medicine and doctors of philosophy in the biologic sciences, bachelors of science and of arts who will receive training in health physics, and other suitably qualified scientific personnel.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

State Medical Election.—At the annual meeting of the Arkansas Medical Society in Little Rock, April 15-17, Dr. Pearlie W. Lutterloh, Jonesboro, was installed as president. Dr. Euclid M. Smith, Hot Springs, was chosen president elect, and Dr. William R. Brooksher, Fort Smith, was reelected secretary. The society voted to hold its 1949 convention in Hot Springs.

CALIFORNIA

International College of Surgeons.—The Southern California Chapter of the International College of Surgeons met May 10 at the University Club of Los Angeles. Papers presented were on the following topics: Dr. F.E. Cooper, "Surgery of Pancreatic Cysts," and Dr. J. Stein, "Malignant Tumors of the Breast."

Seven Year Grant for Research.--The Rockefeller Foundation has granted the California Institute of Technology, Pasadena, $100,000 annually for seven years for research in biology and chemistry as it relates to poliomyelitis and cancer. The institute's research in this field is concentrated on problems in molecular biology. The grant will be combined with others that will make possible a basic research program which, when fully established, will cost $250,000 a year.

Society News.--The California Society of Internal Medicine, meeting at the conclusion of the State Medical Association program April 13, elected Dr. Harold M. F. Behneman, San Francisco, president, and Dr. Donald A. Carson, San Francisco, secretary. The following physicians were elected to honorary membership: Thomas Addis, San Francisco; George Blumer, Pasadena; Robert N. Bramhall, Fair Oaks; Charles Miner Cooper, San Francisco; George Dock, Pasadena; Donald Jackson Frick, Los Angeles; Robert Langley Porter and Herbert C. Moffitt, San Francisco, and Ray Lyman Wilbur, Stanford University.

CONNECTICUT

Annual State Meeting.—Dr. Samuel C. Harvey, professor of surgery, Yale University School of Medicine, New Haven, assumed office as president of the Connecticut State Medical Society at the recent annual meeting. Dr. Charles H. Sprague, Bridgeport, was named president elect. Reelected were: Dr. Cole B. Gibson, Meriden, treasurer; Dr. Creighton Barker, New Haven, executive secretary, and Dr. Stanley B. Weld, Hartford, editor of the *Connecticut State Medical Journal*. Dr. Barker and Dr. Joseph H. Howard, Bridgeport, were named delegates to the American Medical Association, with Dr. W. Holbrook Lowell Jr., Hartford, and Dr. Oliver L. Stringfield, Stamford, as alternates. The meeting was attended by one thousand Connecticut physicians. At the banquet, the speakers were Connecticut's Governor James C. Shannon, and Dr. Edward L. Bortz, Philadelphia, President of the American Medical Association. During the meeting two organizations were formed: Connecticut Diabetes Association, with Dr. Barnett Greenhouse, New Haven, as president; and the Connecticut Physicians' Art Association, which held its first annual exhibit. The house of delegates voted to approve a prepaid medical care plan to be operated by a nonprofit organization of which a majority of the board of directors shall be physicians.

COLORADO

Psychosomatic Medicine for General Practitioners. —An orientation course in psychosomatic medicine, planned chiefly for the needs of the general practitioner, will be held at the University of Colorado School of Medicine, Denver, June 14-26, sponsored by the medical school, the Mental Hygiene Division, U. S. Public Health Service, and the Colorado State Department of Health. The course will comprise lectures at the beginning of each day followed by individual case studies in small groups; in the afternoons there will be group discussions of patients who have been examined. Dr. Harold G. Wolff, associate professor of medicine and psychiatry, Cornell University Medical College, New York, will be in attendance during the course. The program is under the direction of Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado School of Medicine. Inquiries are to be addressed to Dr. Ebaugh. The number of candidates who may be accommodated is limited. There is no tution. A registration fee of $10 is required.

State Society and Press Adopt Code.--The Colorado State Medical Society has brought about the adoption of a code of cooperation between press and radio, hospitals and the medical profession. The medical society agrees to act as an information center or clearing house with twenty-four hour telephone service so its personnel can aid newsmen, and has named a publicity chairman for each of its twenty-six component district societies to be a spokesman for his local group. Hospitals have also named spokesmen. Lists of these representatives will be provided press and radio. Newspapers and radio agree to recognize the doctor-patient relationship and to respect the privacy and legal rights of patients, to strive for utmost accuracy in reporting medical news, and to exercise due editorial judgment in avoiding news which seeks solely to exploit the patient, physician or hospital. The code has been developed as a result of a meeting called last autumn by Dr. John S. Bouslog, Denver, president of the state society, which was attended by news, radio, hospital and medical leaders.

ILLINOIS

Mumps at the Peak.—The state health department announced May 13 that more cases of mumps had then developed this year in Illinois than during all of 1947. Of 6,729 cases in the state, more than 5,000 were reported in Cook County. The incidence showed no signs of declining, the report said.

Narcotic Violation.—The Bureau of Narcotics, Washington, D.C., reports that Dr. Jacob H. West, Champaign, pleaded guilty at Danville to an indictment charging violation of the federal narcotic law and on Oct. 11, 1947 was fined $100 and placed on probation for a period of three years.

Chicago

Personal.—Dr. Israel Davidsohn, Mount Sinai Hospital, Chicago, reported as consultant to the Army Institute of Pathology for the week beginning May 3.—Dr. Jacob P. Greenhill delivered the Samuel and Minnie Good-Friend Memorial Lecture May 3 at Lebanon Memorial Hospital on "Recent Advances in Obstetrics and Gynecology."

Rename Loyola Medical School.—The Loyola University School of Medicine has been renamed the Stritch School of Medicine in honor of Cardinal Stritch. The school is undertaking to raise $12,000,000, part of which is for the new building in the West Side Medical Center, which will house both the medical and dental schools.

Phi Rho Sigma Luncheon.—The Phi Rho Sigma Fraternity has reserved the Chicago Yacht Club, at the foot of Monroe Street, for its American Medical Association luncheon on Wednesday, June 23. Reservations have been made for one hundred and twenty-five persons. Members of the local committee in charge of this meeting are Drs. Robert M. Graham, Lawrence W. Peterson and Howard B. Carroll.

KENTUCKY

Refresher Courses.--The University of Louisville School of Medicine, in cooperation with the Kentucky State Medical Association, is offering refresher courses which will be conducted at the Louisville General Hospital, Louisville, June 1-12. These courses are open to returning medical officers and practicing physicians who are members of their respective state medical associations. Applications will be accepted in the order in which they are received. However, first preference will be given to physicians from Kentucky. Courses in medicine and surgery will be given June 1-5; gynecology and obstetrics, June 7-9 and pediatrics, June 10-12. Instruction will be in the form of lectures, clinics, ward rounds and conferences with emphasis on demonstrations in patients of recent advances in therapy. Instruction will be given from 9 a.m. to 12 noon and 1:30 to 4:30 p.m. A number of part time courses have been arranged. Information regarding fees and schedules may be secured from Dr. Herbert L. Clay, Director, Postgraduate Refresher Training, University of Louisville School of Medicine, 323 East Chestnut Street, Louisville 2.

LOUISIANA

Grants for Research.--The American Cancer Society has awarded grants for cancer research totaling $20,500 to Tulane University of Louisiana School of Medicine, New Orleans. About half of the grant is for the study of testosterone and mammary cancer for the period July 1,1948,until June 1,1949.by Dr. Champ Lyons, associate professor of surgery, and Dr. William Parson, instructor in medicine. The remainder of the grant will be used for research already under way on simultaneous electrophoresis and centrifugation effects in cancer by Robert T. Nieset, Ph. D., associate professor of biophysics, and Malcolm Randolph, of the college of arts and sciences. Bacitracin studies will be extended for another year under a grant of $15,222 from the office of the Surgeon General, U. S. Army. Drs. Alfred B. Longacre, Robert M. Waters and Dr. Florence L. Evans are collaborating in the research.

MISSISSIPPI

State Board of Health.--The following physicians have been appointed to the Mississippi State Board of Health for a period of six years, dating from January 1: Harvey F. Garrison Jr., Jackson; Hugh L. McKinnon, Hattiesburg, and Samuel E. Field, Centreville, the latter a reappointment.

Demonstrations in X-Ray Pelvimetry.—Dr. Frederick W. Goodrich, assistant in obstetrics and gynecology, Yale University School of Medicine, New Haven, Conn., arrived in Mississippi May 3 for a series of demonstrations in roentgen pelvimetry. He was accompanied by Dr. James H. Ferguson, Tulane University of Louisiana School of Medicine, New Orleans. The demonstrations were held as a part of the joint consultation program being done in thirty-three southern Mississippi counties by the university and the state board of health. Demonstrations were conducted at King's Daughters' Hospital, Brookhaven, Mississippi State Charity Hospital, Jackson, South Mississippi Charity Hospital, Laurel, and Forrest County Health Department, Hattiesburg.

MICHIGAN

Personal.—Dr. Mille E. Wilson, for forty-one years on the staff at the Lapeer State Home and Training School, retired April 30.

Health Statistics Conference.—A special conference on public health statistics sponsored by the University of Michigan School of Public Health in cooperation with the Association of State and Territorial Health Officers will be held at Ann Arbor, June 14-18. Four general subjects will be discussed: What Services and What Relationships Do We Need; Collecting and Processing Data; Utilization of Data, and Personnel Needs and Integration of Statistics into Administrative Practice. The course has been planned with the assistance of a committee of state and national authorities in public health. Those wishing to attend should address their requests to Henry F. Vaughan, D.P.H., Dean of the School of Public Health, University of Michigan, Ann Arbor.

MASSACHUSETTS

Expand Cancer Program.—Dr. Henry M. Lemon, a recent appointee to the staff at Boston University School of Medicine, has been appointed coordinator of the expanding cancer research and teaching program at the university. Dr. Lemon will direct the use of a $24,950 grant from the U.S. Public Health Service exclusively for cancer teaching and research. He has previously carried on research work at the University of Chicago Clinics under Dr. O. H. Robertson for the Commission on Air-Borne Infection.

Children's Cancer Foundation.—The Variety Club of New England Children's Cancer Research Foundation was organized March 30 by representatives of the Variety Club of New England and the Children's Hospital, Boston, with an initial fund of $45,536. John J. Dervin was chosen president and Dr. Sidney Farber, chairman of the hospital's division of laboratories and research, will direct the work of the foundation, with the heads of the departments of the Children's Hospital acting as a board of consultation. The Variety Club established the blood bank at the Children's Hospital in 1946 with an annual grant of $10,000. The club is a philanthropic organization of men in theatrical and show business.

MINNESOTA

University Medical Lectures.--Dr. Arthur Grollman, professor of experimental medicine at Southwestern Medical College, Dallas, Texas, gave the annual Duluth Clinic Lectures on May 11-12 at the University of Minnesota Medical School, Minneapolis. He spoke Tuesday at 8 p.m. on "Pathogenesis and Treatment of Hypertension" and Wednesday at 4 p.m. on "The Hypothalamus and Its Disorders." An informal seminar also was held on "The Interrelationship of the Endocrine Organs." David P. Lloyd, Ph. D., of the Rockefeller Institute for Medical Research, will give the annual J. B. Johnston lecture in the Medical Sciences Amphitheater at 8 p.m. May 19, on "Monosynaptic Reflexes and the Myostatic Unit." He will also lecture at the Center for Continuation Study on May 20. The Johnston lectureship was established in 1944 in honor of John Black Johnston, former professor of comparative neurology.

NEW HAMPSHIRE

Annual Meeting of State Society.—The New Hampshire Medical Society will hold its annual meeting at the Hotel Wentworth, New Castle, June 2-3, under the presidency of Dr. John A. Hunter, Dover. The program is made up of round table conferences in the mornings and general meetings in the afternoons. Guest speakers include:

Henry C. Marble, Boston, Compound Injuries of the Hand.
Howard B. Sprague, Boston, Conditions Mistaken for Angina Pectoris and Coronary Thrombosis.
Gerald H. Pratt, New York, Surgical Management of Complications of Diabetes Mellitus.
Grantley W. Taylor, Boston, Carcinoma of the Buccal Cavity.

Drs. Henry W. Hudson Jr., Brookline, Mass., and J. Dellinger Barney, Boston, will take part in the conferences. The banquet will be at 7 p.m. Thursday.

NEW YORK

Rochester Academy Awards.—At a meeting of the Rochester Academy of Medicine, May 4, Dr. Paul W. Beaven, received the Paine Drug prize of $100 for his essay, "An Analysis of Tuberculosis Infection," and Dr. Stuart W. McLeod received the Mead Johnson prize of $100 for his essay on "Barbiturate Poisoning." The Council of Rochester Regional Hospitals' $100 prize for nurses was awarded to Miss Helen M. Yarosz for her essay on "Comprehensive Nursing Care," and Dr. Barbara Ann Wood was presented the John W. MacCauley $25 prize for a paper on "Adrenal Cortical Insufficiency in the Newborn."

Examinations of Boxers and Wrestlers.--The governor has approved a law creating a medical advisory board for the State Athletic Commission. The board, to consist of nine members appointed by the governor, will prepare regulations for the physical examination of professional boxers and wrestlers, recommend qualified physicians to conduct examinations required and the fees to be paid therefor and act in an advisory capacity to the commission. A physician designated by the commission shall be present at every boxing or sparring match or exhibition at the expense of the promoter.

New York City

Research on Alcoholism.—The Research Council on Problems of Alcohol has granted $30,000 to Cornell University Medical College to continue research into the causes and treatment of alcoholism. The grant is the second installment of the five year $159,000 project at the New York Hospital-Cornell Medical Center under the direction of Dr. Oskar Diethelm. The council has also granted $20,000 to the New York University College of Medicine for a study on biochemical and endocrinologic factors in alcoholism. The grant is the second this spring from the Research Council to the college.

University Appointments. -- Dr. Harold W. Brown has been appointed acting director of Columbia University's School of Public Health during the absense of Dr. Harry S. Mustard, who is on leave serving as Commissioner of Health of New York City. Dr. Brown, who has been professor of parasitology at Columbia since 1943, received his doctor of science degree at Johns Hopkins, his medical degree at Vanderbilt University School of Medicine, Nashville, Tenn., and a degree of doctor of public health at Harvard University, Boston. During the war he worked with the Navy on new drugs for the treatment of tropical disease and was consultant to the Secretary of War. Dr. Cushman D. Haagensen, associate professor of surgery, has been appointed coordinator of cancer teaching in the College of Physicians and Surgeons of Columbia University. The coordination project was made possible by a grant of $23,976 from the U. S. Public Health Service. Dr. Haagensen is a graduate of Harvard Medical School. He is also assistant attending surgeon and assistant surgical pathologist to the Presbyterian Hospital.

NORTH CAROLINA

University News.—Dr. Angus Crawford Randolph has joined the staff of the department of neuropsychiatry at Bowman Gray School of Medicine, Winston-Salem, as senior resident in psychiatry at Graylyn, the school's rehabilitation and rest center. Dr. Randolph is a graduate of Princeton University and the University of Virginia Department of Medicine, Charlottesville, Va., and is a veteran of the army air force medical corps.

Recent grants made to the Bowman Gray School of Medicine include one of $1,000 from the executive committee of the North Carolina division of the American Cancer Society,Inc., to pay for a refresher course in cancer for state physicians; two grants totaling $31,300 came from the National Cancer Institute of the U.S. Public Health Service to aid in cancer teaching under the direction of Dr. Robert P. Morehead, head of the department of pathology. A grant of $5,950 was made by the National Advisory Health Council for study of the formation of phospholipids by the liver in cirrhosis of the liver. Radioactive materials from the atomic pile are being used in this study.

OKLAHOMA

Postgraduate Courses.--The summer session of the Postgraduate Medical Course for Resident Physicians and Interns at Hillcrest Memorial Hospital, Tulsa, began May 3 and will extend through August with one lecture each day, Monday through Friday, at 6 p.m. with the exception of the Clinical Pathological Conference, which starts at 7 p.m. Although this course is primarily for the house staff, any doctor who is a member of his local county society is urged to attend at any time. There is no fee. The fall session will begin in September.

PENNSYLVANIA

Councilor District Annual Meetings.--Four Councilor Districts of the Medical Society of the State of Pennsylvania will hold annual meetings early in June. The Second Councilor District will meet at the Golf and Country Club, West Chester, June 2 beginning at 12:30 p.m. The speakers will be Chauncey L. Palmer, Pittsburgh, "Pending Health Legislation," and Paul N. Jepson, Philadelphia, "Treatment of Painful Shoulder."

The Eleventh Councilor District will meet at the Country Club, Uniontown, June 2 at 10 a.m. The program is as follows:

Paul Staman, Uniontown, Characteristics of the Allergic Child.
Othello S. Kough, Uniontown, Cancer of the Lung.
Leroy C. Waggoner, Brownsville, Practical Considerations of the Connective Tissue.
L. Dale Johnson, Connellsville, Office Treatment of Diabetes Mellitus.
William H. Mease, Uniontown, Female Sterility.
Floyd H. Bragdon, Pittsburgh, Neurosurgical Problems in General Practice.
Frank J. Gregg, Pittsburgh, Physiologic Principals in Management of Heart Failure.

On June 3 the Fifth Councilor District will meet at the West Shore Country Club, Camp Hill, near Harrisburg, at 10 a.m. Those present will hear: Pascal F. Lucchesi, Philadelphia, "Shifting Role of Preventive Medicine;" Louis B. LaPlace, Philadelphia, "Chronic Illness"; William Dunbar, Philadelphia, "Rehabilitation of the Chronically Ill"; Mr. Lester H. Perry, Harrisburg, "Public Relations," and Chauncey L. Palmer, Pittsburgh, "Pending Health Legislation."

The Sixth Councilor District will meet at the Green Gables Hotel, Lewistown, June 9 at 12 noon. Speakers will be:

Chauncey L. Palmer, Pittsburgh, Pending Health Legislation.

Mr. Lester H. Perry, Harrisburg, Improving Public Relations.
Thomas M. Durant, Philadelphia, Treatment of Congestive Failure.
Louis B. LaPlace, Philadelphia, Problems of Geriatrics.

SOUTH DAKOTA

Annual State Medical Meeting. -- The South Dakota State Medical Association will hold its annual meeting in the Coliseum, Sioux Falls, May 30 to June 1, under the presidency of Dr. H. Russell Brown, Watertown. Guest speakers will be:

Marvie H. Petersen, Chicago, The National Physicians Committee.
Harry M. Weber, Rochester, Minn., Early Diagnosis of Intestinal Neoplasm.
Jay A. Myers, Minneapolis, Minn., Eradication of Tuberculosis -- Your Responsibility.
Emil D. W. Hauser, Chicago, Orthopedic Care of Polio Patients.
Henry L. Williams, Rochester, Minn., Classification and Treatment of Common Types of Headache.
Donald W. Hastings, Minneapolis, Minn., Psychosomatic Aspects of the Gastrointestinal Tract.
Albert W. Diddle, Dallas, Texas, Noninvasive Cervical Cancer.
Nathaniel G. Alcock, Iowa City, Iowa, Tumors of the Adult Kidney.
Walter L. Bierring, Des Moines, Iowa, Public Health and the Practicing Physician.
Walter A. Fansler, Minneapolis, Minn., Polyps of the Colon and Rectum.
Charles H. Slocumb, Rochester, Minn., Vitamin Toxicity.
Max M. Peet, Ann Arbor, Mich., Splanchnicectomy in Treatment of Hypertension.
L. Fernald Foster, Bay City, Mich., Medical Economics in a World of Change.
Francis W. Lynch, St. Paul, Minn., Treatment of Common Dermatoses.
Carroll E. Roach, Indianapolis, Ind., Developments in Active Immunization.
A. Graham Asher, Kansas City, Mo., Advances in Cardiology.

The annual banquet will be at the Cataract Hotel, May 31, with Dr. Morris Fishbein, Editor of THE JOURNAL, speaking on " A Century of Medical Progress." The Woman's Auxiliary and the South Dakota Academy of Ophthalmology and Otolaryngology will meet in conjunction with the state society.

TEXAS

Hardin Memorial Fund. — A Southwestern Medical Foundation memorial fund, in honor of the late Dr. Hal W. Hardin, Dallas, has been established by Dallas naval reserve officer friends of the physician and other friends. Dr. Hardin, who died Dec. 29, 1947, was clinical instructor in ophthalmology at Southwestern Medical College and staff member of Baylor Hospital.

Institute of Alcohol Studies.—The Yale Institute of Alcohol Studies in the Southwest was formally inaugurated at a two day celebration in Fort Worth May 14-15. Yale University is establishing a long range research and clinical center in cooperation with Texas Christian University, Fort Worth. At the inaugural dinner in public health activities, representatives of state and county medical societies, the presidents of Texas universities and of the state universities of New Mexico, Oklahoma and Arkansas were present. The Yale Institute of Alcohol Studies in the Southwest will comprise the following activities: (1) research unit in the social sciences at Texas Christian University, (2) clinic for the rehabilitation of alcoholic persons at Dallas, (3) summer school of alcohol studies at Trinity University, San Antonio and (4) informal educational activities at all levels throughout the state. Administration of the institute will be centered at the Yale Laboratory of Applied Physiology to assure tested experience and expertness in the field. Dr. Howard W. Haggard and Elvin M. Jellinek, Sc.D., New Haven, Conn., director of the institute and a Texas advisory board will determine the broad policies of the institute.

GENERAL

Postgraduate Committees Luncheon.—The Associated States Postgraduate Committees will have a luncheon meeting June 23 at the Palmer House, Chicago.

Receives Richards Medal.--Edwin J. Cohn, Ph. D., chairman of the department of physical chemistry, Harvard Medical School, Boston, was awarded the 1948 Theodore William Richards Medal of the northeastern section of the American Chemical Society, May 13. Dr. Cohn is known for his work in combating disease and shock through research in the chemistry of the blood.

Society for the Study of Sterility.--The annual national conference of the American Society for the Study of Sterility will be held at the Congress Hotel, Chicago, June 21-22. Invited speakers include: Drs. Charles B. Huggins, Chicago, Melvin R. Cohen, Chicago, Ira I. Kaplan, New York, Dr. M. James Whitelaw, Phoenix, Ariz., and Dr. Oscar Schneller, Philadelphia. The registration fee is $5.

Dr. Hamilton Receives Van Meter Prize Award. — Dr. C. Ferrill Hamilton, Rochester, Minn., fellow in medicine, was given the Van Meter Prize Award of the American Association for the Study of Goiter at a meeting in Toronto, May 6 - 8. The award was offered for the best essay on original work on problems related to the thyroid gland. Dr. Hamilton's paper is entitled "Radioiodocasein: Its Action, Fate and Distribution in the Human."

Annual Meeting of Neurologists.--The American Neurological Association will hold its annual meeting June 14-16 at the Hotel Claridge, Atlantic City, N. J., under the presidency of Dr. George Wilson, Philadelphia. Guest speakers from the European continent include: Birger Kaada, Arne Torkildsen, and Kristian Kristiansen of Oslo, Sweden. In addition, numerous papers will be presented by members of the association.

Polio Emergency Volunteers Handbook.--The National Foundation for Infantile Paralysis has prepared the 1948 Polio Emergency Volunteers Handbook, which is ready for distribution. It explains how a chapter initiates and carries out the emergency program in both rural and urban areas. About 10,000 Polio Emergency Volunteers have been trained by the National Foundation in a project experimental three years ago but now of proved worth. Copies may be obtained free of charge by writing the foundation at 120 Broadway, New York 5.

New Director of Cancer Society.--Dr. Charles S. Cameron, New York, associated with the American Cancer Society, Inc., since 1946, was appointed medical and scientific director at a board meeting in Chicago in February. He has served in the various capacities of assistant, acting and associate medical and scientific director, as well as director, of the service department. He is also a consultant in cancer control to the U.S. Public Health Service and is clinical assistant surgeon at Memorial Hospital, New York

Urology Prize Essay Fund.—The Southeastern Section of the American Urological Association announces receipt of a $1,000 donation from Mr. and Mrs. William R. McEwen, Fort Lauderdale, Fla. The fund is to be used to stimulate research on the problem of "Urinary Bladder Dysfunction." An award of $250 will be made for the best essay presented before the annual meeting of the Southeastern Section. Competition is open to physicians who have graduated from medical school within the past ten years. Information may be obtained from Dr. Russell B. Carson, 408 Sweet Building, Fort Lauderdale, Fla., who is secretary-treasurer, Southeastern Section, American Urological Association.

Grants for Pharmaceutical Research.—The Purdue Research Foundation has received $2,500 from Pitman-Moore Company, Division of Allied Laboratories, Inc., for the purpose of developing and improving medicinal products. The investigations under this project will be directed by Glenn L. Jenkins, Ph.D., dean of the Purdue University School of Pharmacy, Lafayette, Ind. Another grant of $2,000 was made by the company to the Committee for the Promotion of Medical Research, Inc., New York. Dr. Robert C. Batterman will supervise the work under this grant.

Conference of State Associations Officers.--The annual Conference of Presidents and other Officers of State Medical Associations will meet at the Sheraton Hotel, Chicago, June 20, 12:30-5:00 p.m., under the presidency of Dr. L. Howard Schriver, Cincinnati. The group will be addressed by:

Joseph H. Howard, Bridgeport, Conn., Despotism by Consent of the Governed.

Paul R. Hawley, Washington, D.C., The Blue Shield-Blue Cross Program.

John W. Cline, San Francisco, Why a State Medical Association?

International Congresses.--The International Federation of Sport-Medicine has announced its general assembly will be held June 29 in Prague, Czechoslovakia. The Seventh International Medical Congress of Physical Education will be held July 1-5 in connection with the XI Sokol Festival, Prague. At the conclusion of the congress, trips through Czechoslovakia will be organized for the members. The application fee of KCS 400 allows for the railway reduction for the participation at the Sokol festival and for the congress publication. Applications from abroad should be sent to Prof. MUDr. Jiri Kral, Praha II, Vladislovova 15, Czechoslovakia.

Esmond Long to Edit Tuberculosis Journal.--Dr. Esmond R. Long, Philadelphia, director of medical research and therapy, National Tuberculosis Association, has been named editor in chief of the *American Review of Tubercolosis*. to succeed the late Dr. Max Pinner. A new position of managing editor has been created and Dr. Walsh McDermott, associate professor of medicine, Cornell University Medical School, New York, has been appointed. Editorial offices of the publication are being returned to New York from Oakland, Calif., where they were transferred in 1946. Dr. Long, who is also director of the Henry Phipps Institute, Philadelphia, has been director of the National Tuberculosis Association's medical research since January 1947. He is a past president of the National Tuberculosis Association and is a consultant to the United States Army, the Veterans Administration and the U.S. Public Health Service.

Interamerican Cardiological Congress.—The Third Interamerican Cardiological Congress will be held at Michael Reese Hospital, Chicago, June 13-17. Visiting chairmen of the scientific sessions include: John Hepburn, Toronto, Canada; Hernan Alessandri, Santiago, Chile; Luis Ortega Verdes, Havana, Cuba; Cecil C. Birchard, Montreal, Canada; Salvador Aceves and Teofilo Ortiz Ramirez, Mexico, D.F., Mexico; Roberto Vedoya, Buenos Aires, Argentina; Augustin Castellanos y Gonzales, Havana, Cuba; Ignazio Chavez, Mexico, D.F., Mexico; Pedro Cossio, Buenos Aires, Argentina; Arturo Rosenblueth, Mexico, D.F., Mexico; Rafael M. Alzamora, Lima, Peru; Ramon M. Aixala, Havana, Cuba, and Gustav Nylin, Stockholm, Sweden. Among individuals from various nations who will present papers are: Mohamed R. Kenawy, Cairo, Egypt; Gustav Nylin, Stockholm, Sweden; Nicandro Chavez, Mexico, D.F., Mexico; Imre Zarday, Budapest, Hungary; Johannes Barthomeus Kleyn, Hague, Netherlands; Pierre Rijlant, Brussels, Belgium; Kenneth I. Melville, Montreal, Canada; Max Winternitz, Trutnov, Czechoslovakia, and Albert A.F. Peel, Glasgow, Scotland.

A banquet for official delegates and foreign members and guests of the congress will be given June 14 at the Stevens Hotel. On Tuesday evening, delegates, foreign members and guests of the congress will be entertained at a banquet at the Stevens Hotel by the American representatives of the first and second congresses. On Wednesday from 9 to 12 p.m. the directors of Michael Reese Hospital will hold a reception at the Drake Hotel.

CORRECTIONS

Polymyxin.--In the article on "Polymyxin" in THE JOURNAL, April 24, on page 1097 the LD 50 in mice should have been stated at 250 to 300 mg. per kilogram instead of 50 to 300 mg.

Charles H. Scheifley.--The foregoing is the correct spelling of this author's name, and he is with the Division of Medicine, Mayo Clinic, Rochester, Minn., rather than with the Division of Medicine, Northwestern University Medical School, Chicago, as was indicated in THE JOURNAL, March 20, page 819.

Appointments and Promotions.--Dr. Isidor C. Rubin, lately appointed clinical professor in the department of obstetrics and gynecology, New York University College of Medicine, is located in New York City, not Hempstead, N. Y., as stated in THE JOURNAL, April 17, page 1057.

Residency Training Program.--Data regarding the approved residency training program in orthopedic surgery at the Cincinnati General Hospital, Cincinnati, published in THE JOURNAL May 1, page 64, are revised as follows: chief of service, Dr. Joseph A. Freiberg; inpatients treated, 250; number of outpatient visits, 7,048; deaths on service, 3; number of autopsies, 1; assistant residents, 2; residents, 1; service begins, July 1; length of service, one to two years; minimum stipend per month, $25.

Marriages

GEORGE OTTO FRENCH, San Luis Obispo, Calif., to Miss Marion Blascoe of Brooklyn, January 25.

MORRIS J. FINER, Denver, to Miss Helen Pilaszewski of Cicero, Ill., February 7.

HERBERT CAILLE MAIER to JANET STERLING BALDWIN, both of New York, January 10.

SAMUEL LOGAN, New Orleans, to Miss Margot Bennett of Atlanta, recently.

JAMES BLACKMAN HAVRON, South Pittsburg, Tenn., to Miss Carolyn Elizabeth Morgan in Chattanooga, January 10.

JOHN McMAHAN DAVIS, Columbia, S. C., to Miss Mary Burke in Alcolu, January 16.

ROBERT LUCIUS TORNELLO, Youngstown, Ohio, to Miss Jean DeEtte Pullam of Canfield, January 10.

PAUL BERNHARDT TOMS, Salisbury, N. C., to Miss Mabel Bassett Hooker in Martinsville, Va., Dec. 6, 1947.

CARL A BERNTSEN JR., San Francisco, to Miss Anne Proctor Rice in Hamilton, Mass., January 10.

ALBERT G. KING JR. to Miss Nancy Deen, both of Lakeland, Fla., in Philadelphia Dec. 3, 1947.

CUSTIS LANSING COLEMAN, Richmond, Va., to Miss Janet Shaw McGeachy Fisher of St. Pauls, N. C., January 10.

JEROME D. FRANK to Miss Elizabeth Morris Kleeman, both of New York, January 4.

Deaths

Rupert Lee Blue ⊕ Medical Director, U. S. Public Health Service, retired, died in the Roper Hospital at Charleston, S.C., April 12, aged 79, of arteriosclerotic heart disease. Born in North Carolina on May 30, 1868, Dr. Blue received his medical degree from the University of Maryland School of Medicine, Baltimore, in 1892. Immediately thereafter he entered the U. S. Public Health Service as intern, becoming assistant surgeon in 1893, passed assistant surgeon in 1897, surgeon in 1909 and surgeon general from 1912 to 1920. During this time he was stationed at Baltimore, Galveston, Texas, Charleston, S.C., San Francisco, Portland, Ore., Milwaukee, New York, Norfolk, Va., and New Orleans, having been assigned to hospital, quarantine and other public health duties.

Dr. Blue was sent to Italy by President McKinley when cholera threatened our shores in 1900. In 1905 he was second in command of measures taken in New Orleans to eradicate yellow fever. In 1903 and again in 1907 he was placed in charge of plague-eradicative measures in California, where he advanced the idea that rat-proofing is essential to prevent plague in urban communities. As director of sanitation of the Jamestown exposition in 1907, Dr. Blue reduced mosquito-breeding areas to prevent malaria. This experience was later responsible for his special study of tropical diseases at the London School of Tropical Medicine. Then he became adviser to the governor of Hawaii with the object of guarding against the introduction of yellow fever and malaria after the opening of the Panama Canal. It was from this duty that he was called to become Surgeon General. He directed investigations of leprosy which led to the establishment of the federal institution at Carville, La. Under his administration the Public Health Service also inaugurated venereal disease prevention and control work in cooperation with the states. During World War I he was chief of the Federal Health Service, which, with the Red Cross and state boards of health, set up sanitary safeguards in military camps. In May 1928 he served on a board in Washington, D.C., to revise the quarantine regulations, to prevent international transmission of disease by airplane travelers.

Dr. Blue was president of the American Medical Association in 1915, served as president of the Association of Military Surgeons of the United States from 1915 to 1917, was an honorary fellow of the American College of Surgeons and held membership in many other scientific societies. In 1910 he represented the Public Health and Marine Hospital service at the International Medical Congress at Buenos Aires. During a trip to Europe in 1920 he directed efforts to prevent the spread of disease to this country whereby immigrants were examined by officers in twenty-nine European ports. He was a delegate to the International Office on Public Hygiene in Paris, from 1920 to 1923, to the third Decennial Revision of the International Nomenclature of Diseases, adviser to U. S. Mission Lausanne Peace Conference, 1922-1923, and American delegate to the Opium Conference, League of Nations, in Geneva, Switzerland, in 1923. He received honorary degrees from the universities of Maryland, Wisconsin and Michigan. The president of France bestowed on him the insignia of a Chevalier of the Legion of Honor. He retired from the U. S. Public Health Service in 1932.

Reid Hunt, Boston, professor of pharmacology emeritus at Harvard Medical School, died March 10, aged 77, of pneumonia. Dr. Hunt was born in Martinsville, Ohio, April 20, 1870. Following studies at Wilmington College and Ohio University he studied in Germany, then returned to Baltimore, where he received his M.D. degree from the College of Physicians and Surgeons in 1896. After serving as tutor in physiology at Columbia University College of Physicians and Surgeons in New York from 1896 to 1898, he was on the staff of Johns Hopkins University School of Medicine in Baltimore until 1903, first as associate and then as associate professor of pharmacology. From 1902 to 1904 he worked in Ehrlich's Laboratory in Frankfort, Germany, then returned to the United States to take the position of chief of the pharmacologic division in the hygienic laboratory of the U.S. Public Health Service. In 1913 he went to Harvard as professor of pharmacology, becoming professor emeritus in 1936. In 1923 he was visiting professor to Peking-Union Medical College and from 1920 to 1930 president of the United States Pharmacopoeial Convention. He was chairman of the Section on Pharmacology and Therapeutics of the American Medical Association from 1908 to 1909 and a member of the House of Delegates in 1911 and 1912. In 1906 he was appointed a member of the Council on Pharmacy and Chemistry of the Association; he served until 1924, when he was appointed vice chairman, and was chairman from 1927 to 1936, when he resigned. Dr. Hunt was a member of the National Academy of Sciences, the American Academy of Arts and Sciences, the Association of American Physicians, the Leopold-Carol Akademie, the Deutsche Pharmkologie Gesellschafft, the American Physiological Society and the American Society for Pharmacology and Experimental Therapeutics, of which he had been first secretary and the third president. He was chairman of the Northeastern Section of the American Chemical Society and consultant pharmacologist to the Massachusetts Board of Health and to the Chemical Warfare Service of the U.S. Army. He was a member of the permanent standards commission of the League of Nations. Dr. Hunt was at one time a member of the editorial board of the *New England Journal of Medicine* and contributed much to the literature on his speciality.

Abraham Arden Brill ⊕ New York, noted psychiatrist, died at Mount Sinai Hospital March 2, aged 73, of coronary thrombosis Dr. Brill was born in Austria Oct. 12, 1874, was graduated from New York University in 1901 and received his M.D. degree from Columbia University College of Physicians and Surgeons, New York, in 1903. After four years as an assistant physician at the Central Islip (N.Y.) State Hospital he went abroad and studied in Paris, Zurich and Vienna. Returning to the United States, he became chief of the clinic in psychiatry at Columbia University, a post he held from 1911 to 1912. During World War I he was a major in the medical reserve corps of the U.S. Army. Dr. Brill, a specialist certified by the American Board of Psychiatry and Neurology, had been lecturer on psychoanalysis and abnormal psychology at New York University and an assistant professor of psychiatry at the New York Post-Graduate Medical School. At the time of his death he was clinical professor of psychiatry at the New York University College of Medicine and lecturer on psychoanalysis and psychosexual sciences at Columbia University. He was a member of the New York Neurological Society; American Psychopathological Association; American Psychoanalytic Association, of which he was past president; New York Psychoanalytic Society, of which he was honorary president; New York Academy of Medicine; American Psychiatric Association;

Association for Research in Nervous and Mental Diseases; American Association for the Advancement of Science, and the Anthropological Ethnology Society. In 1943 Dr. Brill delivered the Salmon Lectures on psychiatry and mental hygiene at the New York Academy of Medicine. He was consultant at the Manhattan State Hospital and the Veterans Administration Hospital. Among his numerous works were translations into English for the first time of the writings of Freud, including "Psychoanalysis—Its Theories and Practical Application," "Fundamental Conceptions of Psychoanalysis," "Freud's Selected Papers on Hysteria," "Three Contributions to the Theory of Sex," "Freud's Interpretations of Dreams" and "Psychopathology of Everyday Life."

J. Bentley Squier ⊕ New York, professor emeritus of urology at Columbia University College of Physicians and Surgeons, died March 1, aged 74, of coronary thrombosis. Dr. Squier was born in New York Nov. 6, 1873. After graduating from Columbia University College of Physicians and Surgeons, New York, in 1894, he interned at St. Luke's Hospital, then for twelve years was attending surgeon for the City Department of Charities. He was appointed professor of genitourinary surgery at the New York Post-Graduate Medical School in 1909, serving until 1924, and was professor of urology at Columbia University from 1917 until 1939, when he became emeritus professor. In 1917 he aided in forming the staff of the United States Army General Hospital number 1, and during World War I served as a major in the medical reserve corps and as a member of the General Medical Board of the Council of National Defense. A specialist certified by the Board of Urology, Dr. Squier was a member and past president of the American Urological Association, American Association of Genito-Urinary Surgeons and the Medical Society of the County of New York. He was a member of L'Association Internationale d'Urologie and of the Clinical Society of Genito-Urinary Surgeons. Dr. Squier was one of the founders of the American College of Surgeons, of which he was a life member, governor, regent and past president. The Squier Urological Clinic, which he organized and served as director, was established by friends and former patients as a tribute to him at the Columbia-Presbyterian Medical Center. He was consulting surgeon at St. Luke's Hospital and consulting urologist to Roosevelt Hospital and the Neurological Institute. In 1925 he received the Doctor of Laws degree from the University of Pittsburgh and in 1938 was made a Commander of the Order of the North Star by King Gustav V of Sweden.

James Taylor Harrington ⊕ Poughkeepsie, N.Y.; born in New York May 7, 1877; Columbia University College of Physicians and Surgeons, New York, 1906; past president of the Poughkeepsie Academy of Medicine and the Dutchess County Medical Society; formerly member of the board of health and a director of the Dutchess County Health Association; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; served during World War I; attending surgeon at the Vassar Brothers Hospital, where he served as superintendent and chief surgeon; formerly director of the Poughkeepsie Chamber of Commerce, Y.M.C.A. and the Fallkill National Bank; died February 27, aged 70.

Leland Eggleston Cofer ⊕ Surgeon, U.S. Public Health Service, retired, Palm Beach, Fla.; born in Richmond, Va., in 1869; Medical College of Virginia, Richmond, 1889; entered the U.S. Public Health Service in 1890; later placed in charge of the Marine Hospital, Quarantine and Immigration Medical Affairs, in the Hawaiian Islands; served for two terms as assistant surgeon of the United States; at various times a member of the board of health of the city of New York, health officer of the Port of New York and director of the division of industrial hygiene of the New York State Department of Labor; formerly member of the Public Health Committee of the New York Academy of Medicine; died February 17, aged 78, of coronary sclerosis.

Joseph Spragg Evans ⊕ Madison, Wis.; born in West Chester, Pa., March 6, 1875; University of Pennsylvania Department of Medicine, Philadelphia, 1899; emeritus professor of Medicine at the University of Wisconsin Medical School, where he was the first professor of medicine and chairman of the department; at one time instructor in clinical medicine at his alma mater and associate at the William Pepper Laboratory of Clinical Medicine in Philadelphia; fellow of the American College of Physicians; honorary member of the Wisconsin Hospital Association; specialist certified by the American Board of Internal Medicine; affiliated with the State of Wisconsin General Hospital, where he died February 3, aged 72, of arteriosclerosis.

Ernest Frederick Krug ⊕ New York; born in Cleveland Oct. 27, 1877; Columbia University College of Physicians and Surgeons, New York, 1900; formerly associate professor of ophthalmology at the New York Post-Graduate Medical School and Hospital, Columbia University; specialist certified by the American Board of ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the American Ophthalmological Society; served during World War I; consulting ophthalmologist and past president, medical board, Lenox Hill Hospital; affiliated with the New York Post Graduate Hospital; died February 28, aged 70, of a cerebral accident.

Charles Alexander Bailey, Jackson, Miss.; Long Island College Hospital, Brooklyn, 1898; hospital consultant with the Mississippi Commission on Hospital Care; for many years affiliated with the International Health Board of the Rockefeller Foundation, serving in Europe and Latin America; recipient of many awards in this country, Mexico and abroad; at one time health officer of Yazoo County; died February 4, aged 71, of coronary thrombosis.

John Alfred Barton, Fitchburg, Mass.; Harvard Medical School, Boston, 1897; member of the American Medical Association and of the New England Otological and Laryngological Society; affiliated with Burbank Hospital, where he died February 26, aged 73, of Parkinson's disease and uremia.

Charles Coffing Beach ⊕ Hartford, Conn.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1882; past president of Hartford Medical Society; formerly medical director of the Travelers Insurance Company; for many years on the staffs of the Hartford, St. Francis, Mount Sinai and McCook Memorial hospitals; at one time police surgeon; member of the American Museum of Natural History and the Zoological Society of New York; died February 11, aged 91, of coronary disease.

Theodore Bruce Beatty, Ross, Calif.; Rush Medical College, Chicago, 1884; member of the American Medical Association and the Utah State Medical Association; past president of the Conference of State and Provincial Health Authorities of North America; health commissioner of Utah from the time the state department of health was created in 1899 until he retired on July 3, 1935; served as secretary of the state board of health; formerly affiliated with the U.S. Public Health Service; died February 12, aged 84.

Robert Gale Boyd ⊕ Spokane, Wash.; University of Nebraska College of Medicine, Omaha, 1930; past president and secretary of the Spokane County Medical Society; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; affiliated with Sacred Heart, Deaconess and St. Luke's hospitals; died in Berkeley, Calif., February 18, aged 43, of cerebral thrombosis.

William Augustus Boyd ⊕ New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; first vice president of the Bronx County Medical Society when it was chartered; one of the organizers of the Bronx Medical Association, serving as its president in 1910 and later as treasurer; affiliated with the Lincoln Hospital and the Union Hospital, where he died February 20, aged 75, of chronic myocardial disease.

Emery G. Bounell, Hillsboro, Ind.; Medical College of Indiana, Indianapolis, 1895; member of the American Medical Association; served during World War I; on the staff of Culver Hospital, Crawfordsville; president of Hillsboro State Bank and Hillsboro Building and Loan Association; died in St. Elizabeth Hospital, Danville, Ill., February 20, aged 76, as the result of a fall.

Alfred Ernest Braden, Everett, Wash.; Medico-Chirurgical College of Kansas City, Mo., 1905; died in King County Hospital, Seattle, January 21, aged 72, of injuries received in an automobile accident.

Orvis Adoniram Brenenstuhl ⊕ Albany, N.Y.; Albany Medical College, 1913; county coroner's physician for many years; on the staff of the Memorial Hospital; died February 14, aged 59.

Alfred James Bryant, Marshalltown, Iowa; Starling Medical College, Columbus, 1896; affiliated with Decatur County Hospital in Leon; died February 24, aged 78.

Michael Canick ⊕ Brooklyn; Long Island College Hospital, Brooklyn, 1914; served on the staffs of the New York Post-Graduate Medical School and Hospital in New York, Beth El Hospital, Brooklyn Hebrew Home and Hospital for Aged and East New York Dispensary; consulting proctologist at the Brooklyn Womens Hospital; died February 14, aged 60, of coronary occlusion.

Joseph Caplan, Baltimore; University of Virginia Department of Medicine, Charlottesville, 1925; member of the American Medical Association; served during World War I; died February 7, aged 48, of duodenal ulcer and hypernephroma.

James Caloway Carr, Middlesboro, Ky.; Lincoln Memorial University Medical Department, Knoxville, Tenn., 1912; served during World War I; died February 3, aged 60, of hypertensive heart disease.

Francis Patrick Carroll ⊕ Bridgeport, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1914; for six years city physician; past president of the Bridgeport Medical Association; served on the staff of St. Vincent's Hospital, where he died January 2, aged 64, of arteriosclerotic heart disease.

Harvie De Jarnette Coghill ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1926; assistant professor of pediatrics and neuropsychiatry at his alma mater; member of the American Psychiatric Association and the American Orthopsychiatric Association; director of the Memorial Guidance Clinic; died February 6, aged 63, of pneumonia.

John Henry Collins ⊕ Schenectady, N.Y.; University of Vermont College of Medicine, Burlington, 1897; formerly city health commissioner; served on the staff of Ellis Hospital; member of the board of directors and formerly on the staff of the Sunny View Home for Crippled Children; died January 25, aged 78.

Ezra Lincoln Covey, Honor, Mich.; Grand Rapids Medical College, 1899; University of Michigan Homeopathic Medical School, Ann Arbor, 1907; died February 1, aged 74.

Foster Julius Curtis, Salt Lake City; Hahnemann Medical College and Hospital, Chicago, 1905; member of the American Medical Association; served during World War I; commanding officer of the Veterans Administration Hospital; died February 3, aged 66, of cerebral hemorrhage.

Louis Henry Dyke Jr., ⊕ Berkeley, Calif.; University of Southern California School of Medicine, Los Angeles, 1937; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; commander in the medical corps of the U. S. Naval Reserve during World War II; served as president of the California Pathological Society and as secretary of the San Francisco Pathological Society; died February 3, aged 38, of coronary thrombosis.

Thomas Perrine Edmundson, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1912; for many years affiliated with the Shadyside Hospital; died in Tarpon Springs, Fla., February 2, aged 56, of coronary thrombosis.

Calvin H. English ⊕ Fort Wayne, Ind.; Fort Wayne College of Medicine, 1884; formerly chief medical director of the Lincoln National Life Insurance Company; veteran of the Spanish-American War; served on the staffs of Hope and Lutheran Hospitals; died February 4, aged 90, of pneumonia.

Thomas Alpheus Evans, Columbus, Ohio; Rush Medical College, Chicago, 1899; veteran of the Spanish-American War and World War I; served on the staff of the U. S. Veterans Bureau; died in St. Anthony's Hospital February 3, aged 75, following an operation.

Julian Vincent Flaig, Philadelphia; Jefferson Medical College of Philadelphia, 1932; certified by the National Board of Medical Examiners; served during World War II; died in Pennsylvania Hospital Dec. 11, 1947, aged 49, of pulmonary embolus and carcinoma of the pancreas.

Lawrence Eddy Goldman; St. Louis; Washington University School of Medicine, St. Louis, 1928; member of the American Medical Association; specialist certified by the American Board of Pediatrics, Inc.; instructor in clinical pediatrics at his alma mater; on the staffs of the St. Louis Children's and Jewish hospitals, a founder member of the Children's Research Foundation; died February 2, aged 44, of sarcoma.

Jane Lincoln Greeley, Jamestown, N.Y.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1897; member of the American Medical Association; died January 22, aged 83, of mitral regurgitation, influenza and Parkinson's disease.

Albert Molzahn Harris, Sioux Falls, S.D.; Univsity of Nebraska College of Medicine, Omaha, 1939; specialist certified by the American Board of Pathology; at one time instructor in pathology at the University of Arkansas School of Medicine in Little Rock; served during World War II; affiliated with McKennan Hospital and Sioux Valley Hospital; died January 28, aged 35, of brain tumor.

Charles Eleazer Hawkes ⊕ Greenville, R.I.; Harvard Medical School, Boston, 1901; an Affiliate Fellow of the American Medical Association; served during World War I; for many years associated with the Providence schools and Rhode Island Hospital in Providence; died January 31, aged 71, of coronary occlusion.

George Ives ⊕ St. Louis; Johns Hopkins University School of Medicine, Baltimore, 1911; specialist certified by the American Board of Pathology, Inc.; member of the American Society of Clinical Pathologists; affiliated with the Josephine Heitkamp Memorial and Missouri Baptist hospitals; died in the Barnes Hospital February 3, aged 64, of bronchogenic carcinoma.

John C. Lowe, Texarkana, Ark.; Meharry Medical College, Nashville, Tenn., 1900; died February 7, aged 71.

Thatcher Miller ⊕ San Diego, Calif.; College of Physicians and Surgeons, Baltimore, 1906; affiliated with the Mercy Hospital; died January 29, aged 62, of cerebral hemorrhage.

Boyd A. Muster, Lyons, Ky.; Louisville (Ky.) Medical College, 1907; formerly state senator and representative; found dead February 10, aged 65.

Michael Joseph Noone, Scranton, Pa.; University of Vermont College of Medicine, Burlington, 1904; censor of the Lackawanna County Medical Society; member of the American Medical Association; fellow of the American College of Surgeons; for many years affiliated with the Scranton State Hospital, St. Joseph's Children's and Maternity Hospital and the Mercy Hospital, where he died February 3, aged 64, of cerebral hemorrhage.

Carver Haines Osborne ⊕ Brookline, Mass.; Boston University School of Medicine, 1921; died January 3, aged 50, of coronary thrombosis.

Frederick Reis, Boston; Tufts College Medical School, Boston, 1903; member of the American Medical Association; professor of biochemistry at his alma mater; died February 4, aged 71, of cerebral disease.

Howard Risk, Oelwein, Iowa; University of Louisville (Ky.) Medical Department, 1909; member of the American Medical Association; served during World War I; past president of the Fayette County Medical Society; died February 5, aged 68, of cerebral hemorrhage.

Charles Emmet Saulsberry, New Brunswick, N.J.; Jefferson Medical College of Philadelphia, 1894; member of the American Medical Association; died in Piscataway January 1, aged 77, of coronary thrombosis.

Mary I. Thompson Shaffer, Sellersville, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; died Dec. 28, 1947, aged 76, of angina pectoris.

De La Ray Signor, Philadelphia; Medico-Chirurgical College of Philadelphia, 1914; died in a local hospital Dec. 10, 1947, aged 60, of status asthmaticus.

Frederick Glazier Smith ⊕ Somerville, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893; past president of the Somerville Medical Society; during World War II served as a member of the Selective Service Board; affiliated with the Somerville Hospital; died January 9, aged 80, of coronary thrombosis.

Ellis H. Spainhour, Winston-Salem, N. C.; (licensed in North Carolina in 1898); member of American Medical Association; on the visiting staff of City Memorial Hospital; died Dec. 17, 1947, aged 76, of heart disease.

Fred K. Strasser, Hemet, Calif.; Homeopathic Medical College of Missouri, St. Louis, 1889; died January 20, aged 92, of heart disease.

Harold Linson Stratton, Worcester, Mass.; Tufts College Medical School, Boston, 1939; member of the American Medical Association; interned at Lowell General Hospital in Lowell, Mass.; served a residency at Boston State Hospital in Boston and the Worcester State Hospital; certified by the National Board of Medical Examiners; died in the Worcester City Hospital January 31, aged 57, of aneurysm of the arch of the aorta.

Charles Ira Trullinger, Harrisburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; member of the American Medical Association; for many years on the staff of the Harrisburg Hospital; died January 21, aged 66, of uremia, nephrosclerosis and arteriosclerosis.

Alvin Preston Utterback, Brackettville, Texas; University of Nashville Medical Department, 1910; member of the American Medical Association; city and county health officer and local physician for the Southern Pacific Railroad; past president and secretary of the Medina-Uvalde-Maverick-Val-Verde-Edwards-Real-Kinney-Terrell-Zavala Counties Medical Society; died in a hospital at New Orleans January 4, aged 59, after an operation for carcinoma of the right lung.

Luigi P. Verde, Boston; Regia Università di Napoli Facolta di Medicina e Chirurgia, Italy, 1900; member of the American Medical Association; died January 8, aged 72, of coronary occlusion.

Edward Francis Weir ⊕ Meadville, Mo.; University Medical College of Kansas City, Mo., 1899; president of the Linn County Medical Society; died January 30, aged 70, of heart disease.

Joseph Coulter Wiley, McKeesport, Pa.; University of Louisville (Ky.) School of Medicine, 1913; served during World War I; died Dec. 19, 1947, aged 60, of multiple sclerosis.

Edgar M. Wilson, Jefferson, Wis., Northwestern University Medical School, Chicago, 1891; died January 1, aged 83.

H. Fitzhugh Wolford, McKinney, Texas; Memphis (Tenn.) Hospital Medical College, 1904; member of the American Medical Association; past president of the Collin County Medical Society; served as city health officer; died January 6, aged 65, of heart disease.

William S. Wray, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1894; an officer during World War I; served as secretary of the Medical Club of Philadelphia; died in the Germantown Hospital February 2, aged 74, of gastric ulcer with hemorrhage and bronchopneumonia.

Francis Oliver Yost ⊕ Los Angeles; Harvard Medical School, Boston, 1893; one of the founders and formerly professor of pediatrics at the College of Physicians and Surgeons; died in the California Hospital January 30, aged 76, of carcinoma of the colon.

Randall Zimmerman, Wilmerding, Pa.; Jefferson Medical College of Philadelphia, 1904; died in Los Angeles Dec. 11, 1947, aged 68, of coronary occlusion.

George Frederick Zinninger ⊕ Canton, Ohio; Starling Medical College, Columbus, 1892; member of the House of Delegates of the American Medical Association in 1932, 1933, 1937 and 1938; past president of the Stark County Medical Society; died January 28, aged 80.

Attempt to Compose the Differences Between Government and Medical Association

In the conflict between the British Medical Association and the government over the National Health Service the Royal Colleges of Physicians, Surgeons and Obstetricians and Gynecologists have made an attempt at mediation. The Royal College of Physicians has sent to the Minister of Health two resolutions. The College affirms its desire for unity and recognizes that the comprehensive health service cannot be successful without the willing cooperation of all branches of the medical profession. It believes that this can be furthered if the Minister of Health makes clear in an amending act that a whole time service shall not be introduced by regulation, but that if any future government desires to introduce such a service a fresh Act of Parliament would be necessary. The college of physicians reaffirms its opposition to a whole time service. Second, it states that a principal cause of the present discontent with the National Health Service is the power possessed by the Minister of Health to change its character by regulations. The college therefore suggests that an amending bill be introduced to make regulations that affect the service subject to special procedure.

These resolutions of the Royal College of Physicians have received the general approval of the Council of the Royal College of Surgeons. In a letter to the Minister of Health the president wrote: "It is thought, however, that while the legislation suggested would relieve members of the medical profession of one of their most serious apprehensions, it would not be sufficient to secure the cooperation of all branches of the profession. It is therefore hoped that you will make such modifications in the present plans for the National Health Service, particularly in regard to the method of remuneration of general practitioners, as will bring them more into line with the views of the large majority of doctors and thus encourage members of the profession to give the service their general support."

In the House of Commons the Minister of Health, Mr. Bevan, replied. He said that he had been trying to determine what was really and sincerely worrying the doctor. No doubt as experience was gained many modifications would be found which would improve the scheme. But it seemed to him that beyond this the key to the physicians' uneasiness was some instinctive fear that the real objective of the act was a full time state medical service. He had given an assurance to the contrary for the present government, but he could not read into the minds of future governments. However, it now seemed clear to him that more than a spoken assurance was needed, and he was willing to do anything to banish apprehension for good. The Royal College of Physicians had made useful suggestions, with which the other royal colleges agreed, that he should make it statutorily clear that a whole time service would not be brought in by regulation but would require further legislation to make it possible. His colleagues and he accepted that most cordially. With regard to the disputed effect of the act on partnership agreements, he was about to set up an expert legal committee to advise him.

He then dealt with the profession's objection to the part payment of physicians by a sum of $1,200 a year as the "thin edge of the wedge" of a system of total payment in this way, and so the prelude to a whole time service. He had always considered it an assurance for the young beginner to have this payment. However, if physicians read sinister intentions in this, the object could be achieved in another way. Let all new entrants to practice have this assured payment of $1,200 for a period of, say, three years. Then let each decide for himself whether to forego it and pass to a system of plain capitation fees. He had no intention of interfering with the ordinary rights of doctors to express themselves in speech and writing with absolute freedom.

These statements of the Minister of Health were received with approval in all parts of the House of Commons and also by the council of the British Medical Association. A further meeting between representatives of the association and the minister has been arranged. The association has arranged the following: (1) With view to clarifying the situation a small number of written questions shall be submitted to the minister. (2) The minister shall be asked to discuss immediately the questions submitted. (3) After the minister's replies have been received and considered, another plebiscite of the whole profession is to be carried out by the association, as it is believed that no decision should be taken without this step.

Membership of the British Medical Association

The latest figures show that of 68,350 doctors registered in the British Isles 58,195 are members of the British Medical Association, a record number. This is 75 per cent of the total number, and, if retired practitioners are eliminated, amounts to 77.5 per cent. Between 1935 and 1940 the associations' membership increased by 5,000, but since 1940 the apprehensions aroused by the scheme of the socialist government to nationalize the practice of medicine have produced the unprecedented increase of 19,000.

Postgraduate Students from Czechoslovakia

In consequence of the downfall of Germany and the disastrous effects of her occupation of other European countries, Britain has become more than ever a medical Mecca. As the latest manifestation of this, eighty young Czechoslovak doctors are to work this year in British hospitals, as arranged by the ministers of health of both countries. They will attend hospitals in London, Birmingham, Bristol, Cardiff, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, Newcastle and Sheffield. Fifteen will be in Britain for three months, the remainder for a shorter time.

Rio de Janiero, April 16, 1948.

Relationship Between Some Factors of the Vitamin B Complex

Dr. F. A. Moura Campos, professor of physiology at the University of São Paulo, recently published a new paper on the series of experiments he is performing on the physiology of vitamins. He reports the interrelationship between some factors of the vitamin B complex. Association of thiamine and riboflavin was considered first, and later of thiamine and pyridoxine. It was shown that thiamine is necessary to the complete utilization of riboflavin. In animals deprived of viatmin B_1 the growing capacity of riboflavin was not fully observed. In animals deprived of vitamin B_2 the *biologic activity of thiamine was reduced.* Pyridoxine increases the activity of thiamine in connection with the cure and prevention of beriberi. Wistar rats received a diet free from vitamin B complex. When the first attack of beriberi was observed thiamine was given, and the length of the interval until the next attack was recorded. This interval was called the protecting period. In earlier experiments it was seen that the length of the period was gradually reduced. In the present paper it was shown that pyridoxine given together with thiamine could lengthen the rotecting period. Dr. Campos believes that to lain the sparing capacity of pyridoxine its fect on the metabolism of the lipids should be considered.

Incidence of Diabetes

Dr. Vasco Azambuja, of the Nossa Senhora do Socorro Hospital, an institution which serves a district of Rio de Janerio with a population of poor economic condition, published a paper on the incidence of diabetes in 5,000 women examined at the outpatient department of that hospital and 635 men in treatment on the wards. The cases of diabetes discovered among the women were 14, or 2.8 per thousand, and among the men were 6, or 9.5 per thousand. For the total of 5,635 patients of both sexes there were 20 cases of diabetes, or 3.5 per thousand. This is a low incidence of the disease, as has been shown for the whole country, in particular a few years ago by Dr. F. Carvalho Nunes in a detailed study previously reported. An important contribution to this low incidence is the relatively young age of the population of Rio de Janeiro (average age 26.5 years for Rio de Janeiro in 1940, as against 31.1 years for the United States in the same year). The average age of the 635 men was 41.4 years and that of the 5,000 women was 33 years. The low percentage of Jews in the population of Rio de Janeiro is certainly also a contributing factor. Still another factor is the low contribution of proteins in the diet of the population, as shown by a high hydrocarbon intake, varying from 60 to 80 per cent of the total caloric value of the diet in different sections of Brazil. In a large percentage of Dr. Azambuja's cases diabetes was associated with other diseases: 70.8 per cent of the diabetic patients had arterial hypertension, 41.6 per cent had syphilis, 23 per cent had rheumatism of various forms, 20.8 per cent had anemia, 12.5 per cent had pathologic conditions of the biliary ducts and 4.1 per cent had pulmonary tuberculosis. *In the majority of* the 20 cases the diabetes was of a slight and benign f

Cam Against Manson's Schistosomiasis

Dr. Geth of the field staff of the Oswaldo Cruz
Institute, pu progress rep on the experimental
demonstration laxis of M 's schistosomiasis at
Catende count Pernambuco. st district of the
county was cho onstratic of the favorable
conditions it pr easy acce , dams and
ponds; the relati isity of , and the
high degree of ised l service of
the local sugar mi rt of population
lives on the shores of the Panelas River, which is used for bathing, fishing and laundry purposes, and for the disposal of excreta. The commonest snail of this district is Tropicorbis centimetralis, of which 2,631 specimens were examined with 199, or 7.56 per cent, positive for Schistosoma mansoni. Microscopic examination of the feces of 6,559 persons showed that *3,482 were positive for S. mansoni.* The campaign against schistosomiasis, conducted for two years, has included five measures: (1) destruction of the intermediary host by the use of slaked lime; (2) the medical treatment of human carriers of the parasite; (3) construction of public baths and public tanks to discourage the use of the river for bathing and laundering; (4) construction of sanitary privies to decrease the contamination of soil and water, and (5) health education and propaganda. For the destruction of intermediary hosts twenty-seven applications of slaked lime were made at three month intervals, following the technic employed by Luttermoser in Venezuela (four to five parts per thousand). The measure was so effective that after a few applications of lime it was difficult to find snails in the district. But the results are temporary, as the snails increase after cessation of the applications. For the treatment of human carriers of the parasite several antimony preparations were tried. The best results were obtained by intravenous injections of antimony and potassium tartrate. A total of 1,990 persons were treated.

Shigellosis in Children

Dysentery, mainly bacillary, is still prevalent in Rio de Janeiro, as revealed by an average annual death rate of 8.5 per hundred thousand persons for the last three years. As a contribution to the solution of this problem, Drs. Arlindo de Assis and Vera L. Ribeiro, of the Fernandes Figueira Hospital for Children, published the results of an investigation of 1,331 children whose feces were examined for Shigellae. There were 807 children with intestinal discharges containing mucus, pus or blood, and in 237 of them (29.4 per cent) the authors could isolate various types of *Shigellae.*

Among 138 children examined post mortem, only 11 clinically had been suspected of intestinal disease, and 4 of these presented intestinal lesions produced by Shigellae; 3 others showed similar lesions caused by a special type of Proteus morgani characterized by a specific flagellar antigen common to all these pathogenic cultures. Postmortem examination of the 127 children without previous suspicion of intestinal disease disclosed lesions of acute enteritis as the cause of death of 22 of them. Six others, whose death was ascribed to nonintestinal diseases, presented concomitant specific enteritis by Shigellae.

These facts emphasize the importance of sources of infection in members of the household who are carriers of bacillary dysentery. Forty-five per cent of the Shigellae disclosed were of the Flexner group, with predominance of types I, II, III, I.III and II.VII (Weil). In decreasing importance there were Shigella paradysenteriae (18.7 per cent), Shigella alkalescens type I (9.9 per cent), Shigella dysenteriae (7 per cent), Shigella dispar type I Assis (7 per cent), Shigella ambigua (4.8 per cent), bacilli of the Large-Sachs group (2.6 per cent), Pr. morgani (2.2 per cent), Sh. dispar type II Assis (0.7 per cent) and individual samples of Sh. alkalescens types II and III and Sh. pseudodispar Assis.

Brief Items

The Brazilian Society of Sterility was founded recently in Rio de Janeiro, to study the medical and social problems related to sterility, abortion and contraceptive practices. The first president of the society is Dr. Arnaldo de Moraes, professor of clinical gynecology, University of Rio de Janeiro; the governing board includes Drs. Goulart de Andrade, A. Campos de Paz and Clovis C. Costa.

Medical Motion Pictures

FILM REVIEWS

The Fenestration Operation for Otosclerosis. 16 mm., color, silent, 1,175 feet (one reel), showing time forty-three minutes. Prepared by George E. Shambaugh Jr., M.D., Northwestern University Medical School, Chicago. Produced in 1947 by Mervin La Rue, Inc., Chicago. Endoscopic photography by Paul H. Holinger, M.D. Procurable on loan from the Audio-Visual Medical Education Department, Northwestern University Medical School, Chicago.

The details of the operation usually followed with difficulty even by an assistant, owing to the depth of the field and limited exposure, are clearly demonstrated. They are photographed in this production with such magnification as to make the fenestra, which is slightly over 1 mm. in width, clearly visible. The membranous labyrinth which is thereby exposed is also seen easily. The views of the surgical procedures are preceded by a series of diagrams and animated drawings to demonstrate the anatomy, the normal action of the sound-conducting mechanism, the development of a typical otosclerotic focus and its limiting effect on movement of the stapes, the various steps in the surgical procedure and, finally, the action of the new fenestra in enabling sound to reach the inner ear.

The animated drawings of the surgical procedures give a clear conception of the surgical objectives, and the repetition of the appropriate sections previous to each step in the operation is of great value in clarifying the procedure. The value placed on some minor details of technic such as continuous irrigation, wide exposure of enchondral bone beyond the fenestrated area and the use of a smooth gold burr in preventing osteogenesis may meet with some question on the basis of evidence so far available. From the point of view of physiology and acoustics a weakness exists in the portrayal of the action of the sound-conducting mechanism, since such details as axis of rotation, reduction of amplitude of movement and rocking motion of the stapes are not shown; also, the validity of the interpretation of the acoustics of the new conducting mechanism has yet to be established.

An objection may be raised that the references to results of the operation in the latter part of the film fail to give adequate information. In its present state a false impression may be created both as to end results to be expected and the relative value of a hearing aid. Since these questions have been raised in the film, the necessity is created for supplying fuller information as to failures and partial failures as well as to the degrees and percentages of successes. Such information could be easily added. From the surgical point of view the film is an excellent demonstration of the objectives and the surgical technic. The perfection with which the latter is carried out may fail to impress sufficiently the care and precision employed in its execution. The film is well captioned. It is suitable for otologists, general medical audiences and graduate students.

Appendicitis in Childhood. 16 mm., black and white, sound, 1,600 feet (one reel), showing time forty minutes. Prepared in 1941 by Joseph Brennemann, M.D., formerly professor of pediatrics, University of Southern California School of Medicine, Los Angeles. Produced by and procurable on loan from Mead Johnson & Company, Evansville, Ind.

The author gives a summary of his observations on appendicitis in childhood. This film will long be important because it expresses the author's sound clinical judgment. As a historical film it will be of interest for years to come. This lecture film shows only Dr. Brennemann. A few charts are used to illustrate his talk. His gestures are pointed and effectively supplement the spoken word. The film will hold the interest of those professionally interested in the clinical manifestations and the differential diagnosis of acute appendicitis in children. This film can be recommended to pediatricians, surgeons, general practitioners and medical students.

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS
BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, May 22, page 406.

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: Parts I & II. Various centers, June 21-23. Final date for filing application is May 22. Exec. Sec., Mr. Everett S. Elwood, 225 S. 115th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology: Written. Various Centers, July 16. Oral. Philadelphia, Oct. 10. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 22.

American Board of Dermatology & Syphilology: Oral. Groups A & B. Ann Arbor, Oct. 21-23. Final date for filing application is Aug. 2, 1948. Written. Ann Arbor, Sept. 9, Sec., Dr. G. M. Lewis, 66 E. 66th St., New York 21.

American Board of Internal Medicine: Written, Oct. 18. Final date for filing application is June 1. Asst., Sec-Treas., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Oral. Chicago, June 1949. Final date for filing application in Jan. 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology: Part I. Various Centers, Feb. 4, 1949. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 1.

American Board of Opnthalmology: Oral. Chicago, Oct. 6. Written. Various centers, Jan. 1949. Final date for filing application is July 1, 1948. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopedic Surgery: Part II. Chicago, January 1949. Final date for filing application is August 15. Sec., Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14.

American Board of Otolaryngology: Oral. Chicago, June 15-19. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Chicago, Oct. 8-9. Final date for filing application is Oct. 1. Sec., Dr. Robert A. Moore, 507 Euclid Ave., St. Louis.

American Board of Pediatrics: Chicago, June 25-27. Seattle, Sept. 10-12. Atlantic City, Nov. 17-19. Written, July 30. Sec., Dr. Lee F. Hill, 718 Royal Union Bldg., Des Moines, Iowa.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the hometown of applicants. Sec.-Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis.

American Board of Psychiatry and Neurology: Oral. All Groups, San Francisco, October. Final date for filing application is July 15. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: Nov. Final date for filing application is Sept. 1. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: Written. Part I. Oct. Final date for filing application is July 1. Sec., Dr. J. S. Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Chicago, Feb. 12-16, 1949. Sec., Dr. Harry Culver, Route #13, Sunnyside Rd., Minneapolis 4.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Paternity: Results of Blood-Grouping Test Not Binding On Jury.—The plaintiff filed a bastardy action against the defendant, alleging him to be the father of a child born to her on May 23, 1946. From a judgment for the plaintiff, following a jury trial, and from an order overruling the defendant's motion for a new trial, the defendant appealed to the Supreme Judicial Court of Maine.

There was ample evidence, said the court, to satisfy the jury that the defendant had sexual intercourse with the complainant on Aug. 12, 1945 and that she gave birth to a child on May 23, 1946. Except for the blood-grouping test referred to later, there was no evidence whatsoever that any one other than the defendant could have been responsible for her pregnancy. He did not take the stand to deny her story and in conversations with her mother and father inferentially admitted that he was responsible for her condition. In accordance with the provisions of Revised Statutes 1944, chapter 153, section 34, the court ordered a blood-grouping test to be made to determine whether or not the paternity of the defendant could be excluded. The value of these tests in determining the issue of nonpaternity, said the Supreme Judicial Court, was recognized by the legislature of this state nine years ago when the aforementioned statute was enacted. This statute makes it mandatory for the court, on motion of the defendant in a bastardy case, to order such a test and makes the result admissible in evidence where it shows nonpaternity. The tests in the instant case were made by, or at least under the direction of, Dr. Hooker, one of the leaders in this research work. According to his testimony they show that the mother's blood group formula is O-M-N, that the child's is O-M, and that the defendant's is A-N. A and O in these cases refer to what are called groups, M and N to types. And the doctor states categorically that it is a biologic law that a male with type N blood cannot be the father of a child with type M blood by a mother with type M blood. By the application of this law to the case before us, he definitely excludes the defendant as the father of this child.

We are not disposed, said the Supreme Judicial Court, to close our minds to conclusions which science tells us are established. Nor do we propose to lay down as a rule of law that the triers of fact may reject what science says is true. The application of scientific principles to the facts of a particular case, however, where so many important issues, life and death, legitimacy or illegitimacy, and the right of inheritance, may be involved, still remains the province of the court. We have here, the court continued, a clearcut question: In the face of unrefuted evidence that the complainant and the respondent had sexual intercourse on a certain date, that a child was born within the normal period of gestation, and in the absence of any evidence that any one else could have been the father of that child, must we accept the testimony of the doctor as to the blood tests as conclusive on the issue of nonpaternity? In weighing the overwhelming evidence for the plaintiff, outside of the blood tests, did not the jury have the right to decide that there may have been some error in the handling of blood or serums or some mistake in the conclusions of laboratory technicians as to what they found? We do not believe that the statute intended to make the result of a blood-grouping test conclusive on the issue of nonpaternity. It says only that the result of such test "shall be admissible in evidence." In a case where testimony is conflicting or where access by others to the plaintiff may be shown, such test may be decisive, but that is not the case before us. To sustain defendant's motion would be to hold as a matter of law that such a blood test is conclusive. That we cannot do. The statute does not require it, and no case which we have found so holds. Believing as we do that the jury could, in considering all the testimony, have rejected the accuracy of the blood-grouping tests in this instance, the court concluded, we cannot say that their finding is manifestly wrong. Accordingly the judgment in favor of the plaintiff was affirmed and the defendant's motion for a new trial overruled.—*Jordan v. Davis, 57 A. (2d) 209 (Maine, 1948).*

Charitable Hospitals: Effect of Indemnity Insurance on Liability for Negligence.—The plaintiff filed suit against the defendant hospital for damages alleged to have resulted in the death of his infant son caused by the negligence of the defendant and its servants and agents. From a verdict and judgment in favor of the plaintiff the defendant appealed to the Supreme Court of Errors of Connecticut.

The determinative issue on this appeal, said the Supreme Court of Errors, is the effect to be accorded to the existence of insurance on the immunity of a charitable hospital for tort liability. The plaintiff, as administrator, charged the hospital and its servants and agents with negligence causing the death of his infant son, in answer to which the defendant alleged that it was a charitable corporation. The plaintiff pleaded in reply thereto that the defendant carried insurance indemnifying it and its property, funds and assets against all liability for negligence and agreed to limit his recovery to the indemnity procurable under the insurance policy. He argued that by carrying insurance and thus protecting its trust funds and other property from depletion the defendant was estopped from claiming the charitable immunity. At the trial the plaintiff admitted that the defendant was a charitable corporation and the defendant admitted that it was insured.

The plaintiff's claim, said the Supreme Court of Errors, has a certain meritorious basis, for, except as to premiums, the funds of the hospital are protected to the extent of the collectible insurance when it is insured. Nevertheless, it is not valid. If the charitable institution is not liable for the negligence alleged, it cannot be made liable because it took out insurance which would cover a judgment recovered against it. The fact is irrelevant to the question of liability. Continuing, the Supreme Court of Errors pointed out that if the plaintiff's contention should prevail, the result would be that a plaintiff negligently injured in an insured hospital would get judgment while a plaintiff injured in an uninsured hospital would not. The distinction, the court concluded, has no logical basis. Accordingly the judgment in favor of the plaintiff was set aside and a new trial was ordered.—*Cristini v. Griffin Hospital, 57 A. (2d) 262 (Conn., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Syphilis: Review of Recent Literature. F.W. Reynolds and J.E. Moore.-p. 85.

Lipomelanotic Hyperplasia of Lymph Nodes.--Laipply reports 6 cases of chronic dermatitis, pruritus and lymphadenopathy. He stresses that chronic dermatitis, particularly when accompained with pruritus,may result in a characteristic type of hyperlasia of lymph nodes. The lymph nodes are usually moderately enlarged, discrete, firm and nontender. They frequently have a yellow tinge and occasionally show dark brown mottling. The microscopic features include slight distortion of the normal architectural pattern, severe hyperplasia of reticular cells, which contain melanin and sudanotropic droplets, and infiltration with eosinophils. The secondary centers of the lymph follicles are sometimes evident, but the notable proliferation of reticular cells is in the pulp of the lymph nodes. In many instances an incorrect clinical diagnosis of lymphoblastoma may be made because of the prominence of the lymphadenopathy. A diagnosis of lipomelanotic reticular hyperplasia of lymph nodes does not preclude the possibility of the concomitant existence of a lymphoblastoma. Thus in 2 of the cases reported in this paper there were changes in the blood and tissues that warranted the diagnosis of Schilling's monocytic leukosis. Lipomelanotic reticular hyperplasia of lymph nodes is a benign lesion that is secondary to chronic pruritic dermatitis. Although it may be associated with leukemia, Hodgkin's disease or lymphosarcoma, it has no direct relationship to them.

Chronic Recurrent Pancreatitis.--Maimon and his associates review observations on 20 cases of recurrent pancreatitis, 12 in men and 8 in women. Half of the patients were less than 50 years of age. In 8 the symptoms had been present for less than 1 year, in 12 the average duration was four years. The condition is characterized by repeated bouts of severe pain in the upper part of the abdomen. A diabetic type of curve following the oral test for dextrose tolerance in the presence of such attacks suggests the presence of pancreatitis. Pancreatic calcifications are not infrequently found roentgenologically. Disturbances of carbohydrate metabolism are frequent. Steatorrhea is not uncommon. The possibility of pancreatitis must be especially considered in cases in which the patient continues to have attacks of pain simulating that of biliary colic after cholecystectomy has been performed.

Chronic Carbon Dioxide Poisoning. Meessen points out that employees of wine cellars and cold storage plants using solid carbon dioxide and crews of submarines may undergo prolonged exposure to an atmosphere containing sublethal concentrations of carbon dioxide. He describes anatomic reactions observed in dogs, rabbits, guinea pigs and rats exposed repeatedly and over long periods to sublethal doses of atmospheric carbon dioxide. The animals presented degenerative changes in the lungs, the liver, the kidney and the brain. These lesions were the result of the increased carbon dioxide tension and were not caused by anoxemia.

Streptomycin in Army Hospitals.-Pulaski and Seeley say that the investigation of streptomycin that was begun in 1945 is still continuing. They review experiences with streptomycin in 1,200 patients. The wide variation in sensitivity of bacterial species to streptomycin emphasizes the importance of checking the causative organisms in the laboratory for their susceptibility prior to therapy wherever possible. Present indications for streptomycin include gram-negative infections of the urinary tract; tularemia, bacteremia, pneumonia and meningitis due to susceptible organisms, and certain otolaryngologic conditions associated with gram-negative bacteria. Bacterial pneumonitides caused by streptomycin-susceptible organisms are likely to manifest good responses. Results in bronchiectasis and empyema have not been spectacular. Acute brucellosis with bacteremia was favorably influenced when streptomycin was given in combination with sulfadiazine. Streptomycin is of no value against chronic brucellosis. Results in typhoid have not been encouraging. Streptomycin shows promise in the treatment of bacillary dysentery refractory to sulfonamide drugs and in some types of Salmonella infection. It may be influential in bringing about a remission in active idiopathic ulcerative colitis with severe secondary infection caused by susceptible organisms. The drug is not useful against amebic colitis. Striking results have been obtained with streptomycin therapy in a few patients with early diffuse peritonitis, but the most consistent beneficial effects were noted when the streptomycin was given in combination with penicillin. Streptomycin is complementary to penicillin in the surgical management of wound infections and may be of value in certain lesions heavily infected with fecal organisms. Streptomycin has been useful in certain forms of tuberculosis, but its use is not without danger. Untoward reactions, especially on the vestibular portion of the eighth cranial nerve, are a common feature of the courses of therapy necessary to affect tuberculous lesions. These effects are slow to reverse themselves, and some damage may be permanent.

Serologic Studies of Influenza.-Finland and his co-workers state that both influenza B and influenza A were prevalent in Boston during the winter of 1945-1946. Influenza B was responsible for the major outbreak that occurred in December 1945, and no acute cases proved to be due to this virus were encountered after the first week in January. Cases of serologically proved influenza A were encountered almost entirely after the middle of January. Two cases were observed in which there was definite serologic evidence of consecutive infections first with influenza B and a few weeks later with influenza A. There was also some evidence of symptomless infections with viruses of both types. Almost all the patients in whose serums a rise in specific antibodies to one or another of the influenza viruses was demonstrated had respiratory and systemic symptoms which were characteristic of clinical influenza. Similar symptoms were noted during the same period in other persons whose serums failed to show such a rise. A large proportion of the patients who failed to show a rise in influenzal antibodies, however, had an illness which was more like the common cold or had predominantly gastrointestinal symptoms.

Effect of Dietary Restriction of B-Complex Vitamins and Protein on Excretion of Creatinine by Human Subjects. T. E. Friedemann, Velma M. Kinney, G. H. Berryman and others. —p. 117.

Effect of Vegetarian Diets on Reproduction of Rats.—Carlson and Hoelzel found that rats on vegetarian self selection diets including corn (whole kernels), wheat (whole grains), pearled barley, rolled oats, sunflower seeds, peanuts, soy beans, green peas, corn germ meal, wheat germ meal, brewers' yeast, alfalfa leaf meal, sodium chloride, lettuce and celery cabbage were found to be generally fertile but raised less than 25 per cent of their offspring. They raised none in winter. The growth of these young was also subnormal, and severe rickets commonly developed.

Fat Utilization and Low Protein.--French, Black and Swift in previous studies had demonstrated that liberal amounts of fat in the diet of the growing rat resulted in a superior energy utilization of the diet as a whole. In the preparation of the diets used in these experiments an effort was made to furnish all nutrients in optimum quantities for the most efficient utilization of the food energy, including an excellent quality of protein mixture furnishing 22 per cent protein in the diet. In view of the shortages of foodstuffs in many areas, especially of fat and protein, it seemed of further interest to investigate the effect of decreases in the dietary protein in similar high and low fat diets on the resultant utilization of energy. Studies on rats indicated that decreasing the protein intake from the former level of 22 per cent to 7 per cent of the diet did not alter the previously reported superior energy utilization of high fat diets by the growing rat. In the present experiment an increased weight gain, increased body gains of fat and energy and decreased heat production were associated with the high fat ration.

*Obesity at Puberty. R. Lemieux and A. Martel. -p. 60.

Bismuth Therapy of Syphilis.—Gaumond treated 10 patients, 5 men and 3 women between the ages of 50 and 73, one girl aged 14 and 1 man aged 26, who had primo-secondary syphilis, with a bismuth compound alone. Various bismuth preparations were used, all of them insoluble bismuth salts containing 0.0646 Gm. to 0.08 Gm. of metallic bismuth per cubic centimeter. The dose injected by muscular route varied from 1 to 2 cc. Treatment was initiated with two to three injections per week. A course of treatment consisted of twelve to twenty injections. A two weeks' rest was given between the first and second series of injections, and the rest periods were prolonged with progress of the treatment. The total number of injections varied from seventeen to one hundred and fourteen. Except for mild gingivitis there were no untoward reactions. The patients were followed for one and a half to nine years. Nine patients had strongly, positive Bordet-Wassermann and Kahn reactions before treatment was instituted. The tenth patient showed Treponema pallidum in dark field examination. After six to nine months of the treatment the serum of all the patients became negative. The cutaneous mucosal lesions healed rapidly. On the average, nine months' treatment with two injections per week, the rest intervals not counted, seems to be sufficient to obtain a cure. In patients over 50 years of age treatment with trivalent arsenic is contraindicated. Basic treatment with a bismuth salt combined with penicillin may be the method of choice for early syphilis.

Obesity at Puberty.--Lemieux and Martel report 56 obese children, 38 girls and 18 boys, between the ages of 12 and 16 years. In contrast to earlier concepts it is suggested that obesity at puberty need not be caused by an endocrine disorder. Cases of hypophysial obesity are rare and cases of hypothyroid obesity are less frequent than usually believed. Twenty-four of the children had a normal basal metabolic rate; in 29 the basal metabolic rate was lowered and in 3 instances it was increased. There was almost no increase in the cholesterol level of the blood which may be considered as a more reliable proof of the activity of the thyroid in children. In 90 to 95 per cent of the cases an alimentary factor must be considered as the basic cause of the obesity, although the possibility of a temporary deviation in the endocrine system or the hypothalamus should not be excluded. The gluttony of the obese children may be favored by a psychological factor associated with lack of emotional maturity. Simple obesity seldom interferes with the course of puberty, which was normal in 33 of the author's cases, precocious in 14 and delayed only in 9. The obese children should be placed on a diet which provides for a daily ration of about 1,200 calories comprising 80 to 100 Gm. of carbohydrates, 60 to 80 Gm. of proteins and 40 to 50 Gm. of fats. Dextro-amphetamine administered in doses of 2.5 mg. before every meal diminishes the appetite and at the same time increases the physical capacity by intensifying the desire for activity. The administration of theophylline or of ammonium chloride may mobilize the endema of the tissues. Thyroid therapy is to be employed only in cases in which the basal metabolic rate is below 10 per cent.

Background of Cancer Control Program. J. H. Kler. -p.27.

Occupational Beryllium Poisoning.--The Martlands and Brodkin present 4 fatal cases of beryllium poisoning. The first case occurred in 1934 but at that time was not recognized as having been caused by beryllium. In 1944 deaths were occurring among workers in a fluorescent lamp factory in Massachusetts who were exposed to a phosphor containing zinc beryllium silicate. The late Dr. L. U. Gardner of Saranac, N.Y., found a chronic pulmonary granulomatosis closely resembling a sarcoid as the cause of death in these patients and they were spoken of as the "Salem sarcoids." A case referred to the medical examiner of New Jersey in 1944 showed lesions practically identical to the so-called "Salem sarcoids." This case, which is the second of the 4 fatal ones presented here, again illustrates the difficulty in recognition of chronic beryllium poisoning. The third and fourth cases reviewed here were observed in 1947. Based on a study of these 4 cases, the Van Ordstrand report describing the exposure, symptomatology and pathology of acute beryllium poisoning, the Hardy and Tabershaw report describing the exposure, symptomatology and findings in chronic beryllium poisoning and the research done at Saranac by Gardner, who put chronic beryllium poisoning on a firm pathologic basis and produced the lesions in experimental animals, the authors are of the opinion that industrial beryllium poisoning is well established. In addition, in case 4 the recovery of beryllium in most of the organs allows to complete the postulates used in medicolegal work. The authors discuss the incidence, the signs and symptoms, the roentgenologic aspects, the differential diagnosis, the treatment and the compensation aspects of beryllium poisoning.

Etiology of Fibrositis: Review. M. Valentine. -p. 241.

Psychogenic Rheumatism.—Boland lists disturbances in the gastrointestinal, cardiovascular, respiratory, genitourinary and nervous systems and in the skin that are generally recognized as psychosomatic. He points out that physicians are not so familiar with the fact that disabilities of the locomotor system frequently result from psychic causes. He shows that psychogenic rheumatism must be included among the common rheumatic disorders along with osteoarthritis, rheumatoid arthritis, primary fibrositis and rheumatic fever. Its incidence was appallingly high among soldiers with musculoskeletal incapacities admitted to military general hospitals and special arthritis centers. At such installations psychogenic rheumatism was the most frequent cause of disability (34 per cent) in 450 consecutive cases of soldiers with rheumatic complaints admitted to an Army general hospital in the United States. Diagnosis of psychogenic rheumatism depends on (1) absence of organic disease or insufficient disease to account for the disability, (2) qualitative functional characteristics of the disability and (3) positive diagnosis of psychopathology. The most common symptoms are pain, tenseness, stiffness, limitation of motion, subjective sense of swelling, muscular fatigue and weakness of an involved part. Associated functional manifestations (headaches, dyspepsia, globus hystericus, sighing respirations, precordial pains, insomnia, tremors, cold moist hands and feet, anxiety and nervousness) are present in the majority of cases. In practically all instances evidence of previous neurotic traits may be elicited. The precipitating emotional factors are often difficult to ferret out, but smoldering resentment seems to be the common basic psychopathologic factor in psychogenic rheumatism. In remarks about the terminology the author says that the term psychogenic rheumatism, although objectionable to some, is convenient and compact.

Estrogens and Tumor Genesis.—According to Zondek the question of correlation between the sex hormones and tumor genesis is of utmost clinical and theoretic importance. There exist reports in the literature of benign tumors arising in the genital organs of both women and animals after administration of estrogenic hormone. Carcinogenic effect of estrogen has been reported in rodents and occasionally in monkeys. In the human subject no convincing results could be demonstrated. The fact that estrogen is used for treatment of cancer (prostate, breast) contradicts the carcinogenic action of estrone. He believes that only exceedingly prolonged administration of estrone might cause undesirable results. He advises great caution in the administration of estrogenic hormone in women with cystic mastitis or cervical erosion, as well as in women belonging to cancerous families.

Clinical Picture of Tumors of Adrenal Cortex.—Dahl-Iversen and Højensgaard say that tumors of the adrenal cortex cause sexual hormonal effects, combined sexual and metabolic effects and purely metabolic effects on the organism. Tumors with excess production of androgenic hormones occur in boys and girls before puberty and in women, usually young women. Tumors with combined sexual and metabolic effects are commonest and occur mainly in somewhat younger women. Cortical tumors with purely metabolic changes appear in men and women, more often in women. Hyperplasia and tumors of the adrenal cortex, tumors of the pituitary glands, the pineal glands and the gonads are closely related. Secretion of more than 200 international units of androgen in the urine in twenty-four hours points to a tumor of the adrenal cortex. In differential diagnosis between hypophysis affection and affection of the adrenal cortex the only certain aid is bilateral operative exploration. It is advised in all cases with Cushing's syndrome. Cortical tumors on the left side predominate, and exploration first on this side is in order. Treatment of tumors of the adrenal cortex is operative. Preoperative and postoperative administration of cortical hormones has reduced the operative mortality. The Shipley incision or its modification affords the best access in tumors with known localization. In bilateral exploratory intervention the authors advocate lumbar incision, vertical or diagonal, parallel with the twelfth rib. Two cases of hormone-producing cortical tumors of the adrenals of pure sexual type treated during the past year are described, the one, bilateral, in a woman aged 44, the other, on the right side, in a girl aged 6.

Book Notices

Principles of Occupational Therapy. Edited by Helen S Willard, B.A., O.T.R., Director, Philadelphia School of Occupational Therapy, Philadelphia, and Clare S. Spackman, B.S., M.S. in Ed , O T R., Director, Curative Workshop, Philadelphia School of Occupational Therapy. Cloth Price, $4.50. Pp. 416, with 46 illustrations. J. B Lippincott Co , 227-231 S. 6th St., Philadelphia 5, 1947.

This book reports the work of the authors and nineteen other outstanding leaders who bring together in this volume the principles of occupational therapy. The book points out that principles of occupational therapy have been utilized for centuries in the management of the care of patients. In modern times its value was recognized in World War I, but there was little carryover from the military to civilian hospitals. Great strides were made during World War II, and the importance of its activities in the dynamic program of rehabilitation has made it one of the most talked about subjects in medical service. The development of interest in physical medicine, which includes both occupational and physical therapy, has given further stimulus to training and practice in this field. The authors point out that occupational therapy as a method of treatment can do much to shorten convalescence and improve the degree of recovery. They therefore believe that its methods are destined for broad use in hospitals.

The book is divided into two sections. Section I is entitled "Basic Concepts" and is composed of five chapters. A feature of each chapter which will be appreciated by all who read this book is the boxed-off list of chapter topics. Each topic is capitalized within the chapter, thereby making work with the book especially easy. Section II has fourteen chapters, the larger of which are divided into parts. A good index at the end adds much to the value of this book. In addition to well organized textual material there are numerous blank forms, charts, diagrams and pictures; references to periodicals, books and pamphlets are numerous and appear at the end of each chapter. Doctors, nurses, medical students, social workers and, of course, occupational therapists will want this basic textbook in their libraries because it is interesting and easy to read.

The Story of Hypnotism. By Robert W. Marks. Cloth. Price, $3 Pp. 246. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1947.

The revival of hynotism as a means for treating psychologic disorders has stimulated the public's interest in this controversial subject prematurely. However, the author, writing for the public, has succeeded in presenting the outlines of hypnotism understandingly and accurately. He describes the rise of animal magnetism under Mesmer's influence and its decline caused by bias within medical circles. Hypnotism later revived under medical auspices but again declined as a result of its use as a direct attack on symptoms rather than on their pathogenic complexes. The author proceeds from individual hypnotism to describe examples of mass suggestion and to reveal how crowds have been influenced. This social phenomenon is of topical interest and highlights the value of the book for the education of the public.

Nutrition in Health and Disease. By Lenna F. Cooper. B.S., M.A., M.H.E., Chief, Department of Nutrition, Montefiore Hospital, New York, Edith M. Barber, B.S., M.S., and Helen S. Mitchell, A.B., Ph.D., Dean, School of Home Economics, University of Massachusetts, Amherst, Mass. Tenth edition. Cloth. Price, $4. Pp. 729, with 132 illustrations. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1947.

This textbook for nurses and valuable reference book for dietitians and home makers with training in home economics has been rewritten by a group of authorities with a view to offering a valuable and reliable aid in the teaching of nutrition and diet for both sick and well patients. Emphasized is the fact that therapeutic diets are normal diets modified to suit special needs. The use of a basic dietary pattern is recommended in all instances in order to insure the nutritional adequacy of all diets, even those restricted because of special diseases. Because therapeutic diets are valueless unless eaten, the authors call attention to factors which help to induce the patient to eat; they emphasize that the patient is a person and must be treated and fed as such. The style is simple and direct. The book is divided into four sections of approximately equal length which deal with the principles of nutrition, diet in disease, food selection and preparation, and tabular material and special tests. The double column page is used for ease of reading. The material is well organized and especially adapted to the volume's chief purpose—a textbook for student nurses. As a reference for advanced students there is an abundance of valuable and usable tabular material in the fourth section together with references for special reading. The glossary is valuable to the beginner. The table of contents and a good index makes it easy to find special subject matter.

The Incidence of Neurosis Among Factory Workers. By Russell Fraser, with the collaboration of Elizabeth Bunbury and others. Medical Research Council, Industrial Health Research Board, Report No. 90. Paper. Price, 1s. 3d. Pp. 66, with 23 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1947.

In 1942 Dr. Russell Fraser and his English collaborators, believing that neurotic illness was responsible for a considerable amount of absence from war work, undertook a study of the incidence of neurosis among factory workers. In all, 3,083 adult workers were examined in thirteen light or medium engineering factories in which over 30,000 workers were employed. This number examined represents 80 per cent of the original random sample. The other 20 per cent, for one reason or another, could not be examined. The inquiry was concerned with "recent" health and circumstances during a series of periods of six months between September 1942 and December 1944. The data collected provided information about the health of the workers in the engineering trade under stabilized wartime conditions. "Recent" referred to the past six months and "prewar" to the whole of the worker's prewar life. The term as used in the report concerned any psychologic or mental illness (i. e., any disability for which there was apparently a psychologic cause or partial cause, including anxiety states, mild depressive states, obsessional states, hysteria and also a few instances of psychosis which were discovered among the study group). The term does not include original nervous diseases. Minor neuroses were considered as abnormalities of personality unassociated with symptoms. The main results of the inquiry are clear: 10 per cent of the workers studied suffered from definite or disabling neurotic illness; neurosis caused between one fourth and one third of the absence from work due to illness, and certain features in the individual workers or in their environment were associated with a varying incidence of neurosis. Although the sample was probably as representative as practical in such a study, the sampling limitations leave uncertain the extent to which these findings may be generally applicable. However, in these days of underproduction and manpower shortage, industry can hardly afford to neglect the disturbing implications of Dr. Fraser's report.

Practical Psychiatry and Mental Hygiene. By Samuel W. Hartwell, M.D., Assistant Director, Department of Mental Health, State of Michigan, Division of Mental Hygiene and Child Guidance, Lansing, Mich. Cloth. Price, $3.75. Pp. 439. McGraw-Hill Book Co., Inc., 330 W. 42d St., New York 18, 1947.

A man who has taught psychiatry to nurses for twenty years has published this book to accomplish four goals: (1) to help the student develop a dynamic interest in psychiatry; (2) to make psychiatry more easily understood; (3) to make the teaching of psychiatry practical, and (4) to permit flexible use of the test. The book is divided into four parts, namely, the introductions, medical psychology, psychiatry and mental hygiene. The textual matter is clearly written and easily understood. This book is recommended for the use of the student nurse and the psychiatric social service worker.

Mind and Body: Psychosomatic Medicine. By Flanders Dunbar, M.D. Cloth. Price, $3.50. Pp. 263. Random House, Inc., 457 Madison Ave. New York 22, 1947

This book is intended for the lay reader, although the general physician will also find it interesting and profitable to read. The author writes authoritatively as the pioneer of the subject generally termed psychosomatic medicine. The style is simple and nontechnical, sustaining interest throughout. The most frequent questions and doubts of the people are adequately answered by the contents, which include discussions of typical physical disturbances caused by emotional conflicts. The book is highly recommended.

Unipolar Lead Electrocardiography Including Standard Leads, Unipolar Extremity Leads and Multiple Unipolar Precordial Leads. By Emanuel Goldberger, B.S., M.D., Adjunct Physician, Montefiore Hospital, New York. Fabrikoid. Price, $4. Pp. 182, with 88 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1947.

This monograph was expectantly awaited because the author has done much to popularize the recent development of the so-called unipolar limb leads. A review of this book must deal with two aspects: (*a*) the theory of the unipolar leads and its practical application and (*b*) the adequacy of the presentation of the subject by the author. In its early development with the limb leads, electrocardiography recorded the differences in the electrical effects of the heart on the two electrodes which form each limb lead. With the advent of precordial or chest electrocardiography, the difference in the effect on the two electrodes used in such recording was much greater. The difference in effect approached but did not equal the unipolar method obtained by connecting an electrode on the surface of the exposed heart with an "indifferent" electrode at a distance on the body. Wilson therefore endeavored to obtain a true unipolar precordial, or V, electrocardiogram by using the central terminal which he and his group developed. They published a communication dealing with the possibility of getting similar unipolar leads by connecting the central terminal with an electrode on an extremity. The author amplified and simplified this method with his augmented unipolar, or aV, leads. These V or aV leads, if the theory of the Einthoven triangle is applicable to the human body, should give the electrical effects of the heart only on the exploring electrode. The theory of the Einthoven triangle as a theory is correct. But its application in clinical electrocardiography is still disputed. There is no universal agreement that the postulates which would make the central terminal a null electrode are fulfilled, and actual recording of the potential of the central terminal shows that it is not a true null electrode. As far as precordial leads are concerned the error of this assumption is not too great and the central terminal may be considered as good and under certain circumstances a better "indifferent" electrode than an electrode placed on one of the extremities. However, any deviation actually from the Einthoven theory would make the utilization of a central terminal or Goldberger's modification less reliable in obtaining a true unipolar limb lead. That this is so is shown by the fact that while theoretically the algebraic sum of the records obtained with V_L, V_R and V_F, or with aV_L, aV_R and aV_F, should equal zero, and this Goldberger states in his book; actually this is not so in many cases. For example, in figure 64 of this book the sum of QRS of aV_L, aV_R and aV_F is far from zero. It would appear therefore that the strict interpretation that the V or aV limb leads are truly unipolar leads has not been verified. If the reader bears these facts in mind he may properly evaluate the merits of so-called unipolar lead electrocardiography.

When one turns to the presentation as contrasted with the theory of this book, one will be impressed that the material has been somewhat hastily put together and that the development is not as logical or succinct as in Goldberger's original articles. In addition, one finds that the interpretation of the aV limb leads is largely arrived at empirically as far as normality, abnormality and significance is concerned. Thus, the older electrocardiographer will have to learn a new set of criteria for the so-called unipolar limb leads in addition to those he is already familiar with as far as the ordinary limb leads are concerned.

The exposition of the V chest leads is adequately presented, but this material is now well known and would therefore not by itself justify the publication of a new monograph. The author properly stresses the recent developments concerning the influence on the electrocardiogram of the position of the heart. However, it is an error to believe that this is more readily to be obtained by the use of aV limb leads than by ordinary limb leads, as the reader can determine for himself by referring to the excellent studies with ordinary limb leads which Ashman and his colleagues have published.

There are a number of errors of fact, some minor and some more serious, in the book which the author should correct in the next edition. The style is involved and the text is complex, so that it will be difficult for the beginner. Other publications present the theoretical material more succinctly and clearly.

With all its faults this book is recommended for two groups of readers: (*a*) the established electrocardiographer who desires to evaluate critically this newer development in "unipolar electrocardiography" and (*b*) the beginner in electrocardiography who may find that, despite the fallacies of theory, he obtains a rational analysis of electrocardiography which makes him appreciate the theory and thus makes it easier for him to apply this tool clinically. Both types of readers must be cautioned, however, to avoid the snare that this is an accurate development of the theory. They should recognize that actually the application of theory is a crude approximation of the truth. It cannot be denied that the unipolar limb leads as recorded in this book may turn out to be of value in certain restricted cases, as, for example, in the diagnosis of hypertrophy of the right heart and in the evaluation of Q_3. It is difficult to believe, however, that the so-called unipolar extremity leads will replace the ordinary limb leads. In fact, it would be a great mistake to believe that they add much to one's practical information when one routinely takes precordial leads from at least three chest positions in addition to the ordinary limb leads.

A Study of Individual Children's Diets. By E. M. Widdowson. Medical Research Council, Special Report Series, No. 257. Boards. Price, 6s. Pp. 196, with 93 illustrations. His Majesty's Stationery Office, York House, Kingsway, London, W. C. 2, 1947.

This study comprises observations made on 1,000 children, aged 1 to 18 years, between 1936 to 1939. Dr. Widdowson is well qualified from her previous chemical and analytic studies, which date back to 1925. The study presents many interesting facts, and one is impressed with their careful and thorough analysis. Among the most striking revelations were the rather wide variations in caloric intake which were compatible with good health and average physical development. To the American reader the chapter on "beverages" is of interest. She notes that the "small beer" which for centuries was the customary drink of children has been replaced by tea and also to some extent by milk, the average amount of milk being less than a pint a day. This book will be valuable and instructive for any one interested in nutrition and development in childhood.

Communicable Diseases. By Franklin H. Top, A.B., M.D., M.P.H., Medical Director, Herman Kiefer Hospital, Detroit, and collaborators. Second edition. Cloth. Price, $8.50. Pp. 992, with 108 illustrations. The C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This is the third edition of a deservedly popular work. The author has added to the volume from authoritative sources on coccidioidomycosis, rheumatic fever, epidemic diarrhea and the like so that the book approaches somewhat a textbook of medicine. Although what is said is worth while, it is a question whether too much or not enough has been said and whether the material may not be too much for such a volume. It gives a sparse report on clinical problems which are not considered completely enough. The detail has been carefully worked out and presented, and the author shows an obvious knowledge of up-to-date literature.

Suggestive Therapeutics: A Treatise on the Nature and Uses of Hypnotism. By H. Bernheim, M.D. Translated from the second French edition by Christian A. Herter, M.D. [Originally published in 1889.] Cloth. Price, $5. Pp. 420, with illustrations. London Book Co., 30-41 50th St., Woodside, Queens, New York, 1947.

This reprint of Herter's translation of the classic work on hypnotism is timely because of the revived interest in hypnotism as a therapeutic procedure. Many of the recently discovered phenomena can be read in this original work, indicating that little progress has been made in the field. All who use or contemplate using hypnotism should have this classic work in their library for reference.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

DEATH IN THE BASSINET

To the Editor:—In the February 1948 *Woman's Home Companion* there appears an article, anonymously written, entitled "Death in the Bassinet." In substance the article is an indictment of the medical profession for advising parents to place infant babies in the prone position when sleeping. What is current medical opinion regarding this practice?

M.D., Cobleskill, N.Y.

ANSWER.—The anonymous author reported the sudden death of his 10 month old son. The father feels convinced that the death was due to the fact that the child was placed in his crib in the prone position. One day, when the mother made her bimonthly visit to the pediatrician, it was noted that the friction of the bedding had caused an irritation on the back of the baby's head, so the doctor advised putting the baby face downward during his nap. The mother, acting on the advice of the physician, put the baby in the bassinet in the prone position. The baby was heard to cry, vomited a part of his previous meal and when the parents reached the baby in his bed he had expired.

Evidence is insufficient to prove that the prone position of itself was the cause of sudden death. Most pediatricians have seen many young infants who select by preference the face down position without unfavorable results; though it is granted that many mothers fear this position for their sleeping infants. Pillows should not be permitted either in the bassinet or in the carriage. The mattress should be firm, flat and smooth, so that the baby cannot push his face into a depression. The mattress in the carriage should fit well without space around the edge in which the baby may become wedged. There are many causes for sudden death in infants, most of which can be revealed only by a carefully conducted necropsy.

The formerly accepted diagnosis of thymic death is no longer accepted as meaningful, and most pathologists and clinicians reject this explanation as obsolete. There are some cases on record in which an infant has buried his face in a soft pillow and shut off his supply of air. Not infrequently, cases are reported to the coroner, of babies who have become accidentally strangulated in their beds or carriages with bands of clothing, blankets and restraining garments which have become wound around their necks. Other occasional causes of sudden death are briefly mentioned, such as an acute bronchopneumonia. Spontaneous hemorrhages into the lungs or peritoneal cavity occasionally occur; apoplexy of both adrenal glands has been reported and hyperacute attacks of fever such as meningococcus infections. Some have sought to explain sudden death as the result of an anaphylactic shock. Others have suggested the cause to be laryngospasm of tetany, though symptoms of tetany were not found before the fatal attack. One author thought the fatality was caused by hypoglycemia due to adrenal insufficiency.

One of the common causes of sudden death in young infants is respiratory obstruction from aspirated particles of food or mucus. The obstruction happens when vomiting of stomach contents is associated with crying. Food is thereby drawn into the air passages. Most of these accidents have been observed in infants less than 6 months of age. On necropsy one finds that either a large curd of milk has obstructed the larynx or in other instances there is food (usually milk or cereal) or mucus in the respiratory tract. In some cases infants have been suffocated by aspirating a dusting powder such as stearate of zinc from a container with which the baby was playing. In the London *Lancet*, Feb. 28, 1948, appeared an analysis of recent cases (1945 to 1947) coming under the jurisdiction of the Leeds Coroner's Court: 21 infants aged 9 months or less died suddenly due to aspiration of vomited food stuffs. It is probable that another 10 infants in whom the cause of asphyxia was not ascertained or was reported to be due to some other factor also died as the result of aspiration of regurgitated food substances. Soft feather pillows were held to be responsible for 2 deaths and probably responsible for 4 others. In 1 case suffocation by a shawl was believed responsible for a sudden death.

URINARY COLLOIDS

To the Editor:—Please give references and discuss influence of urinary colloids as related to the formation of stones in the urinary system. Are there satisfactory means of qualitative or quantitative determination of colloids in the urine?

Arthur J. Butt, M.D., Pensacola, Fla.

ANSWER.—The term "urinary colloids" suggests that the inquirer is thinking in terms of specific substances rather than in terms of the state in which some of the urinary constituents may exist. One should speak in terms of the "colloidal state" of substances. Conceivably inorganic substances such as phosphates of calcium and other substances may be held in part in the colloidal state in a fluid like urine. The organic substances which would most likely be involved in bringing about this colloidal state of such inorganic constituents are proteins. A standard quantitative method for determining colloids in urine is not available, but the quantitative estimation of total proteins, calcium phosphates and oxalates might throw some light on the factors which contribute to the colloidal state, which might easily be involved in the formation of stones in the urinary system. In some cases the suspended material in the urine may consist of tissue debris, and this might also be a contributing factor to the formation of calculi. If such cellular debris exists in urine it could, of course, be separated by centrifugation and be identified by appropriate microscopic examination.

CYSTIC OVARIES

To the Editor:—1. (*a*) Is it advisable to leave healthy ovaries after hysterectomies in women before menopause? (*b*) How great is the danger of future development of cystic ovaries? (*c*) Are not the natural hormones secreted by the remaining ovaries better than the substitution therapy of the artificial menopause? 2. A great number of obstetricians claim that low flap cesarean section does not have advantages over classic cesareans. Discuss the types of cesarean section, the intraperitoneal and the extraperitoneal.

M.D., Pennsylvania.

ANSWER.—1. (*a*) Considerable discussion is still taking place on the advisability of leaving healthy ovaries after hysterectomy in women before the menopause. Some prominent gynecologists recommend that ovaries be left after the menopause. Reasons for removing the ovaries are that in a fair number of women there subsequently develop cysts which necessitate another major operation; fair evidence exists that many women near the climacteric go through the menopause within a few years following hysterectomy. One experienced surgeon now leaves the ovaries in women under the age of 40 but removes them in patients 40 years or over. Assuming that the ovaries are normal and other reasons for removal do not exist, recent observations indicate that removal of ovaries may decrease the hazard of cancer of the breast. Therefore women with a family history of frequent cancer should have the added protection of bilateral oophorectomy, especially older women.

(*b*) The incidence of cystic ovaries requiring surgical removal following hysterectomy is obscure. Estimates vary from 5 to 20 per cent depending on the surgical technic.

(*c*) Hormones secreted by a normal ovary are probably better than artificial therapy, but one must remember that a cystic ovary may or may not function abnormally. All women face menopause inevitably unless they die prematurely. Serious catastrophe associated with menopause does not occur when the patient is properly prepared for it and appropriate management is arranged and followed.

2. Obstetricians differ on transperitoneal or intraperitoneal cesarean sections. Generally obstetricians who have thoroughly investigated the virtues of the classic and the low flap cesarean section favor the latter. The most likely exception to the latter procedure would be in placenta previa, particularly when the placenta is on the anterior wall. Many now perform the low flap type. Surgeons should not attempt cesarean sections, classic or otherwise, unless able to do both types. Inquirer is referred to Stander, "Textbook of Obstetrics," and DeLee-Greenhill, "Principles and Practice of Obstetrics."

LEITZ COLORIMETER

To the Editor:—What is the value of the Leitz photoelectric colorimeter? Is it sufficiently reliable to use in the determinations of blood sugar and blood urea and for other laboratory procedures requiring the use of a colorimeter? Are the methods outlined in the handbook which accompanies the colorimeter acceptable, reliable methods? If this colorimeter is not accurate, are there any on the market which are?

M.D., Minnesota.

Answer.—The Leitz clinical photoelectric colorimeter is suitable for many clinical laboratory determinations that depend on the measurement of the depth of color or turbidity of a prepared test solution.

The laboratory procedures outlined in the handbook which accompanies this colorimeter are standard methods adapted for use with the apparatus. Accuracy is well within the limits required for clinical test purposes. The colorimeter may be purchased precalibrated for use.

The use of this instrument or any other colorimeter presumes a knowledge of standard technics and manipulation in the preparation of test materials and reagents.

ARTERIAL INJECTION

To the Editor:—In cases of extreme shock intracardiac injections of "adrenalin" (epinephrine) have been used. Recently this practice has been criticized as being fraught with danger. Please comment on use of epinephrine injected into the common carotid.

D. C. Wilkinson, M.D., Oconomowoc, Wis.

Answer.—A number of drugs have been injected into the arteries of man. Drugs which ordinarily produce arteriolar relaxation, such as papaverine, histamine and acetylbeta-methylcholine chloride, cause rather pronounced improvement in the circulation. It is probable that a significant amount of epinephrine hydrochloride injected intra-arterially will cause sharp and sustained arteriolar constriction which will jeopardize the integrity of the arterial circulation to the brain in a serious way. Certainly epinephrine hydrochloride should not be injected into the carotid artery of man until appropriate studies on animals have been made.

AXILLARY MAMMARY TISSUE

To the Editor:—A woman aged 32 was first seen by me one year ago for pain in both axillas. Over a period of several months the pain in the right axilla totally subsided while that in left persisted. Apparently the pain in the left axilla was cyclic, being more disturbing to the patient at the time of her menstrual period. History indicated that she received 1 mg. diethylstilbestrol daily and daily doses of progesterone 5 mg. in the latter half of her menstrual cycle over a period of six months. The above medications were interrupted during menstruation. When first examined, the patient's skin appeared slightly coarse and her breasts were increased in size. No masses were palpable in the axillas. With total discontinuation of the foregoing medicaments, her complexion reverted to its normal texture and the breasts to their normal size. The pain in her right axilla was the last to disappear, while the pain in the left axilla appeared aggravated with menstruation. For the past few months at menstrual time small lymph node-like areas can be palpated in both axillas. These disappear in the intermenstrual period, but recur at menstruation, when the left axilla becomes tender to palpation. Although these "nodes" have not increased in size since first observed several months ago, the patient is especially concerned about their potentially becoming malignant. What is the etiology of this condition? Is diethylstilbestrol a factor or coincidental? What treatment is recommended?

M.D., Michigan.

Answer.—It is not clear from the query why this patient 32 years of age with normal menstrual cycles was receiving fairly large doses of diethylstilbestrol and of progesterone or whether this was proper treatment. Presumably, these were given for breast pain occurring at time of menstruation but obviously they aggravated the condition.

Probably this patient has masses of mammary tissue in each axilla, a condition often observed for the first time in patients while lactating. The pain noted in each axilla during menstruation is probably due to the cyclic hypertrophy of this mammary tissue aggravated by the medication. These "lumps" are no more likely to become cancerous than any other mammary tissue, unless it is true that overstimulation from diethylstilbestrol leads to cancer.

For treatment, it is suggested that the medication described be considered inappropriate for a woman of this age, particularly in view of the reaction, and therefore be discontinued. Small doses of testicular extract could be substituted for reasonably short periods of time, if necessary and indicated because of pain and swelling; warm wet compresses are helpful.

SKIN GRAFTS

To the Editor:—Please give information and references concerning use of split thickness grafts around colostomies that are causing irritation to the surrounding skin.

Arch J. Beatty, M.D., Longview, Wash.

ANSWER.—In 1941 L. R. Dragstedt, G. M. Dack and J. B. Kirsner (Chronic Ulcerative Colitis, Summary of Evidence Implicating Bacterium Necrophorum as an Etiologic Agent, Ann. Surg. 114:653-661, 1941) described a skin-covered ileostomy as a method of preventing excoriation of the abdominal wall in patients requiring ileostomy for chronic ulcerative colitis or other diseases of the colon. This method has been subsequently used in a number of clinics and found to be satisfactory for this purpose. The method is applicable to a colostomy and may be indicated when the discharges cause severe irritation of the skin. Usually, however, cutaneous irritation can be prevented after a colostomy by adjustment of the diet together with a well fitting colostomy bag.

LEUKEMIA

To the Editor:—Is folic acid of value in the hemorrhages of acute leukemia? Has it any influence on the course of the disease? Will it help the anemia which accompanies acute leukemia?

R. P. Little, M.D., Dwight, Ontario, Canada.

ANSWER.—Folic Acid has been used in several cases of acute leukemia without apparent effect (Doan, C.A., *Am. J.M. Sc.* 212: 257, 1946; Zuelzer, W. W.: *J.A.M.A.* 131:7, 1946). This is to be expected, as folic acid has been found to be effective only in the macrocytic anemias associated with a megaloblastic bone marrow.

PARINAUD'S SYNDROME

To the Editor:—I have recently observed several cases of severe febrile conjuctivitis. The conjunctival bulb is free. The conjunctiva shows large granules on the lower lid only. There is a moderate discharge of liquid pus. The lower lid and its surroundings are edematous. The temperature is about 104 F., but the patients (mostly small children) do not appear sick or have photophobia. In 1 case there was painful enlargement of a preauricular node. Complete cure occurred with sulfonamide drugs and penicillin within three or four days. Other observations to explain the fever are absent.

M.D., Springfield, Mass.

ANSWER.—What is described is probably a Parinaud's syndrome. This is not a disease entity, since many organisms have been reported as the cause of the condition. It is usually a unilateral conjunctivitis associated with an enlarged preauricular node and with mild to high temperatures. Since it is infectious, the second eye may become involved. In this country localized infection with generalized tularemia is not infrequently seen. The course is usually prolonged, but perhaps the sulfonamide drugs and antibiotics may have shortened the course. Leptothrix, streptothrix and tuberculosis have been mentioned as the etiologic factors in cases of Parinaud's conjunctivitis. This, of course may have been only an unusually virulent infection with a pyogenic organism with involvement of the preauricular nodes.

MEDICAL PATENTS

ARCHIE M. PALMER, D.C.L.
Washington, D. C.

Scientific investigators working in university and professional school laboratories are concerned primarily with the formulation of new ideas and the understanding of nature and its laws. The discovery and development of patentable inventions are seldom conscious objectives of their research efforts. They feel with Sir Henry Dale that "the primary and special function of research in the universities is to build the main fabric of knowledge by free and untrammelled inquiry and to be concerned with the practical uses of it only as these arise in the course of a natural development."[1]

Nevertheless, many of these new ideas and discoveries, the result of experiments undertaken with quite a different purpose, may have valuable commercial application or require protection and control in the public interest. Not only may these new ideas and discoveries contribute to scientific and technologic progress and to cultural and social advancement, but they may also be basic to industrial development and expansion. The protection and control provided under the patent laws may have to be invoked to obtain the greatest public benefit and usefulness from these products of scientific research.

Interest in science and scientific research, particularly in the natural sciences and in their application to engineering and medicine, was intensified and accelerated by experiences during the war. However, war is destructive and costly in scientific progress as well as in human life. During a war research projects are largely developmental in nature, designed to meet immediate and urgent needs. The normal course of scientific investigation is interrupted. Research workers are drawn from the laboratory; some never to return. The continuity of research in many fields is broken.

Scientists, industrial leaders and government officials are all concerned over the extent to which our storehouse of fundamental scientific information was depleted during the war and the need for promptly restocking the shelves. Social and national security public and private health and economic prosperity and well-being depend on the constant extension of scientific knowledge and the effective application of that knowledge.

Now that the military emergency is over, science has an opportunity to return to its normal course of free and unregimented research. The pressure of meeting deadlines and achieving urgent developmental objectives is lifted. Research workers and scientific investigators from the university campus and the industrial laboratory aided materially in the magnificent record our nation made in war production and military achievement. Returned now to the campus and the laboratory on release from wartime responsibilities and occupations, they are more research minded than ever. Interest in research is being given further impetus by government and industry, which are turning to universities, professional schools and technologic institutes for assistance in their postwar reconversion programs.

The situation is made more acute by the critical shortage of scientific and technical personnel and the need for developing a new crop, grounded in fundamentals and trained in research procedures. This new supply of qualified scientists to meet the needs of the future as well as of the immediate present must come from the universities and professional schools. At the same time these institutions are expected to continue as centers of basic and fundamental research. During the past several years, largely for war purposes and the national security, we have been using up our storehouse of fundamental knowledge faster than we have been adding to it.

American science faces a challenging future. Whether we are to enter on a rich era of productive research, profiting from our wartime experiences and capitalizing on the present research consciousness among scientists and the public generally, will depend to a large extent on the philosophy behind our university research programs and the administration of those programs. Of direct concern to university administrators and scientists engaged in the formulation and conduct of research programs is the policy or procedure to be followed in handling the results of scientific investigation.

The public welfare, educational objectives, direction of scientific thought and advance of knowledge are all involved. If science is to be mobilized for peacetime purposes as effectively as it was for war and we are to enter on a rich era of productive research, sound policies and procedures must be developed.

As a service to American higher education and to the scientific fraternity, the National Research Council has been making a comprehensive study of this problem. As a first step, a factual survey[2] is being made of the prevailing policies, practices and procedures in educational institutions and nonprofit organizations for the administration of patentable results of scientific research, with a view to the early publication of the findings for the information and guidance of all concerned. Through correspondence, conversations and visits to university and other research centers, information has been assembled concerning existing practices and pres-

ent thinking in administrative and scientific circles, about research policies and patent management programs.

ATTITUDE TOWARD MEDICAL PATENTS

An important—and controversial—aspect of the patent problem in universities and medical schools is concerned with what to do with the patentable products of scientific research that affect public and individual health, particularly discoveries and inventions of a medical, pharmaceutic, therapeutic or hygienic nature. Research scientists, physicians, university administrators, government officials, patent attorneys and industrialists have all given considerable thought to this problem and its relation to the public welfare.

Whether patents on medicinal discoveries and foods are in the public interest was the basis of a joint symposium presented before the Division of Medicinal Chemistry, Biological Chemistry, and Agricultural and Food Chemistry of the American Chemical Society in 1937.[3] The American Medical Association held a conference on medical patents in 1939.[4] Various other groups have given consideration to the subject through the years, and the National Research Council has on several occasions held conferences on patent problems at which medical discoveries have been an important item.

Those universities that have comprehensive patent policies usually include within the scope of general over-all policies discoveries, processes, developments and inventions which may affect individual or public health. A few provide specifically for a different treatment of medical discoveries, designed to discourage patenting except when it is considered necessary in the public interest and then without consideration of profit, either to the individual or to the institution. A considerable number have no fixed policy; when cases arise, they handle each one individually, usually without following any uniform pattern except, as a general rule, to discourage investigators from seeking patents.[5]

The prevailing practices of educational institutions, especially those with medical faculties, are influenced to a considerable extent by the traditional attitude of the medical profession as to the ethics of patenting medicinals and medical appliances. Such an attitude, however, does not necessarily preclude patenting a new process or discovery in the public interest. Yet many scientists working in this field take the position that the results of their research, both patentable and otherwise, should be shared "without fee or stipulation." In so doing they often fail to differentiate between patenting for personal gain and patenting in the public interest.

The principles of medical ethics, enunciated by the American Medical Association, say plainly:

> *It is unprofessional to receive remuneration from patents or copyrights on surgical instruments, appliances, medicines, foods, methods or procedures. It is equally unprofessional by ownership or control of patents or copyrights either to retard or to inhibit research or to restrict the benefit to patients or to the public to be derived therefrom.*[6]

Nevertheless, the American Medical Association, by action of its House of Delegates in June, 1914, has given permission to the Board of Trustees of the Association "to accept, at their discretion, patents for medical and surgical instruments and appliances and to keep these patents as trustees for the benefit of the profession and the public, provided that neither the American Medical Association nor the patentee shall receive remuneration from these patents."[7]

The view has been expressed by some scientific investigators that no patents should be taken out for discoveries or inventions in the medical field which may affect individual or public health and that the control should be left to legislative action. This aversion toward the patenting of medical discoveries is well illustrated by the following statement:

> It should not be necessary . . . to invoke the ethical considerations which seem to many of us to be incompatible with the patenting of principles or methods involved in the maintenance of individual or public health. It seems to us probable that no code of ethics has ever developed from purely abstract considerations, and that in every case where a strong feeling of propriety of action has been transformed into a tradition of behavior, there has been behind it some tangible purpose. Standards of behavior which have developed in all things connected with medicine have sprung from a recognition that there is a sharp line of differentiation between those forms of activity which deal with health and those which are purely commercial. The invention of an improvement in the mechanism of automobiles, or of a shoe-buckle, concerns matters of convenience or luxury, and can be dispensed with easily by those who are forced to do without them. The relief of the sick and the prevention of unnecessary sorrow by the maintenance of individual and public health are matters in a different category. As soon as we are in possession of the knowledge of principles or methods which can contribute to these purposes their free utilization becomes a public necessity; and any procedure which inhibits their most rapid and effective application to the needs of the community would seem to us as unjustified as the cornering of the wheat market or the patenting of the process of making bread.[8]

Through the centuries medicine has given freely of its discoveries for the benefit of mankind, and they have become the property of all who cared to employ them in the control of disease. However, as medicine has become more complex, involving specialized investigation in the fields of biochemistry, physiology, physics and associated branches, great numbers of fulltime research scientists in the hospital and the laboratory work with members of the medical profession but are not bound by the same ethical principles.

Many important medical preparations and technics have been developed in university laboratories, often at considerable expense to the institutions. It will be recalled that it was in the laboratories of the University of Toronto that the possibilities of insulin as a treatment for diabetes were discovered in 1921 by a team of biochemists, physiologists and a practicing physician. It was at Columbia University that a member of the pathology department discovered the antirachitic properties of vitamin D. The use of the ultraviolet ray to enrich the vitamin D content of foods and medicinal products was developed by a biochemist at the University of Wisconsin. It was also a biochemist, working in the laboratories of St. Louis University, who discovered the therapeutic properties of estrone ("theelin"). Similarly, iodobismuthite ("iodobismitol") was developed at Stanford University and thyroxin at the University of Minnesota.

Patenting such discoveries is not considered to be wrong in itself, but to be desirable in order to control them in the public interest. An editorial on "Patenting

Therapeutic Agents," which appeared in the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION in 1919, contains the following pertinent remarks[9]:

> . . . there are occasions when it is wise, if not necessary, to obtain a patent in the interest of the public and, in the case of surgical instruments and medicines, of the medical profession. In certain instances it is absolutely necessary that the article produced shall maintain a definite standard of quality and purity—and, it may be added, shall be sold at a reasonable price. Enterprising pharmaceutical manufacturers have usually been ready to appropriate the results of scientific research by investigators or therapeutic measures suggested by practising physicians. Not infrequently, in such instances, the desire for financial gain has caused the marketing of such products with extravagant, if not false, claims as to their value. Yet the patent laws may be used so as to protect and to benefit the public and the medical profession. In research laboratories, work is being carried on resulting in the production of new therapeutic agents. It is important that these agents shall be so controlled that they may be made available without subordination to commercial interests. It has become practically necessary, therefore, for research workers to protect their products in the interest of the public welfare and scientific medicine. It has not been an easy matter to decide how best to bring about the desired results.

In a report on "The Protection by Patents of Scientific Discoveries," made in 1934, a committee of the American Association for the Advancement of Science summarized the situation as follows[10]:

> The committee recognizes the fact that there exists in many quarters a strong feeling against medical patents. This feeling seems to be largely due to the unpleasant memories of the past exploitation of the public by means of "patent medicines" which had doubtful or decidedly harmful effects on the public health. Government regulation during recent years has eliminated a great deal of misrepresentation and false claims in regard to this class of goods. The Patent Office, moreover, now seldom issues patents for the old-fashioned type of patent medicines. It is therefore an error to class all medical patents with the former types of "patent medicines."
>
> The mere fact that medical patents offer the means of making profit is not a sufficient reason to condemn them entirely . . . patents have other very important uses. Moreover, we must bear in mind that it is possible to obtain profits from medical discoveries in many other ways without resorting to patents if the medical investigator is so inclined. We must, after all, depend upon the integrity and character of the investigator when important medical discoveries are involved.
>
> The ideal to strive for may perhaps be that no medical discoveries should be subject to any restrictions whatsoever In our present commercial economic system, however, and with existing laws and business practises such an ideal is difficult to attain, since not all may live up to it. We must, therefore, guide ourselves in accordance with the economic situation that exists today and seek to attain our ideals through the existing economic machinery rather than to ignore it entirely on the ground of ethical consideration alone.
>
> The act of securing patents for medical discoveries is not unethical in itself, and such act does not necessarily mean that personal profits are sought. Under our existing laws and commercial practises dedication to the public of important medical discoveries by mere publication is not always the best procedure to follow. The public can often be best served by receiving the benefits of a new medical discovery under the control of a patent. . . . Through making a medical discovery it may become the duty of the investigator to make sure by means of patents that the public will actually benefit from his discovery and not be subjected to unfair exploitation by others who may commercialize his discovery.

The committee suggested further that, although in general the ethics of the medical profession may properly prohibit its members and their close associates from obtaining any monetary profits through medical patents, the following possible conditions may sometimes demand recognition.[10]

> (*a*) Where in introducing the medical invention commercial large scale operation is necessary involving expensive equipment and large personnel. In such case the manufacturer must be assured by means of patents that he will not meet with ruinous competition and thereby lose his initial investment in an enterprise for producing a new medical product or apparatus. Before placing a new product on the market a great deal of preliminary work, expensive equipment and salesmanship are necessary, requiring a considerable outlay of capital. No manufacturer would be willing to go to this expense unless he knew that he could obtain an adequate return on this investment through patent protection.
>
> (*b*) Where the expenses incurred in developing the invention were unusually large and the funds were supplied by individual investigators or organizations without the assistance of any public funds. In such cases there is a legitimate reason for recouping the expenses involved in the research. The public should certainly be willing to pay the actual cost for what it gets.
>
> (*c*) Where a medical invention has been made at a university or similar institution having limited funds for research there may be some justifications in such case for obtaining funds by means of patents for further research of the type which will ultimately inure to the public welfare

In order to obtain a comprehensive picture of the present situation in educational institutions with regard to the handling of patents in this field, a special study[11] was made of the practices of the seventy medical schools on the approved list of the Council on Medical Education and Hospitals of the American Medical Association and of the relation of those practices to the general situation in the universities and colleges with which sixty of those schools are affiliated. It was found that: (1) nine of the university-affiliated medical schools have special policies for dealing with medical patents, several of which are applicable on a university-wide basis; (2) nine others conform to formalized general university policies for handling all types of patentable results of scientific research; (3) the other forty-two have no formal or established policy, either in the medical school or in the university at large, although many of the medical schools follow practices which are generally accepted throughout the universities with which they are affiliated; (4) only two of the ten independent medical colleges have clearly defined policies; the other eight either follow informal policies or have no policy at all.

The complexity of the problem and the wide variation of procedure in handling medical discoveries are clearly indicated in the following resumé of prevailing practices in the sixty approved university medical schools and ten independent medical colleges.

SPECIAL PATENT POLICIES

On recommendation of the Faculties of Arts and Sciences, Medicine, Public Health, and Engineering of Harvard University, the following policy[12] in regard to patents on discoveries or inventions bearing on health and therapeutics has been adopted by the President and Fellows of the University, as a university and not merely a medical school policy, dealing with the subject matter of the research rather than the site of its performance:

> No patents primarily concerned with therapeutics or public health may be taken out by any member of the University, except with the consent of the President and Fellows; nor will

[11] Included as part of a comprehensive survey of university patent policies conducted by the National Research Council, the findings of which will be published by the Council early in 1948 in a detailed report including in an appendix the complete texts of thirty-seven definitive university patent policies

[12] A Statement of Policy in Regard to Patents on Discoveries or Inventions Bearing on Health and Therapeutics, Nov. 15, 1939.

such patents be taken out by the University itself except for dedication to the public. The President and Fellows will provide legal advice to any member of the University who desires steps to be taken to prevent the patenting by others of such discoveries or inventions.

In cases as to which it may be deemed necessary to take out a patent and dedicate it to the public in order to prevent others from obtaining a patent for their own benefit, members of the University are asked to report to the dean of the appropriate faculty any such discovery or invention made by them, with a recommendation as to whether an application for patent should be filed, in order that, if necessary, steps may be taken to obtain and dedicate the patent.

A person making any discovery or invention which he thinks should be patented for any other reason should so report to the dean of the Medical School, giving his reasons in full, for submission to the President and Fellows of the University.

Under the By-Laws and Regulations of the Yale Corporation, it is the policy[13] of Yale University that neither the University nor members of any of its faculties should make profits from inventions or discoveries made at the University, or in connection with its activities, and especially from inventions or discoveries which may affect the health or welfare of individuals or of the public. In 1935 the Board of Permanent Officers of the Yale University School of Medicine adopted the following resolution, based on the premise that the patenting of discoveries applicable in the fields of public health and medicine was becoming an increasingly important and controversial problem of wide implication for the public:

> . . . it is, in general, undesirable and contrary to the best interests of medicine and the public to patent any discovery or invention applicable in the fields of public health or medicine; but if, at any time, any member of the faculty deems it necessary solely for the protection of the public, without profit to himself or the University, to control any invention or discovery by means of a patent, he shall bring the matter before the Prudential Committee for consideration before taking any steps toward patenting.[14]

The Prudential Committee of the Corporation is authorized to deal with each case according to its merits. Although no patent has been applied for by any member of the faculty of the School of Medicine during the last twenty-five years, it is the view of the faculty that this should be the basic policy of a school of medicine with respect to inventions or discoveries which affect the health of individuals, with a view to the protection of the public interest. It would be permissible however, under the regulations of the Yale Corporation, to seek a patent if it seemed necessary in the public interest, for the advancement of learning or to maintain the quality of a patentable discovery. Under these circumstances, the probability is that a royalty-free license would be granted to selected manufacturers who could be counted on to maintain proper standards and price.

St. Louis University has generally followed a hands-off policy with regard to patents resulting from scientific research in its several schools, but a special trustee committee has had under consideration for several years the formulation of a formal patent policy for the University. However, in the School of Medicine it has been the recognized practice since 1930 for members of the faculty and research workers to assign voluntarily, without consideration of individual benefit, their patent rights to discoveries in fields in any way related to medicine and public health to a Committee on Grants for Research created in the School of Medicine for the express purpose of administering patents. This committee was established originally to administer the patent on estrone ("theelin") which was assigned by Dr. Edward A. Doisy and his co-workers to St. Louis University for the benefit of the School of Medicine, the eventual income from the licensing of the patent to be used exclusively for the prosecution of research in the School.[15] The procedure followed in the licensing of this patent has served as the basis for the administration of other patents handled by the committee. As in the case of "theelin," the agreements with all licensees provide that "for the purpose of insuring more adequate public service and of fostering further scientific research through the product, the University desires to control the preparation and marketing of the product through its testing laboratory, thereby assuring a distribution for therapeutic purposes of preparations of dependable and uniform character."

While Johns Hopkins University also officially pursues a hands-off policy on patents resulting from scientific research in its various schools, the attitude of the faculties of the School of Medicine and the School of Hygiene and Public Health is definitely averse to the patenting of any inventions or discoveries which may affect the public health. That attitude is expressed in the following resolution, which was adopted by the Advisory Board of the Medical Faculty in 1933[16]:

> The Advisory Board of the Medical Faculty considers it undesirable for any member of the Faculty or anyone connected with the School of Medicine to patent any invention or discovery which may affect the public health; but, in case any member thinks it desirable to secure a patent, he should bring the matter before the Advisory Board before so doing.

At the University of Cincinnati it is the policy with respect to inventions, discoveries and developments relating to medicine, therapeutics and hygiene:

> . . . to discourage the acquisition of patents by faculty members, students or other persons connected with the teaching and research staffs or by any agency of the University, except when the control provided by patent rights appears to be necessary or desirable in relation to the public welfare. Therefore, it is strongly recommended that patentable inventions and discoveries of this type as well as investigative work that is clearly pointed toward such patentable inventions or discoveries, be brought to the attention of the dean of the faculty to which the inventor belongs, and by the dean reported to the administrative authorities of the University, to the end that action, in keeping with the rights and wishes of the inventor and appropriate to the public responsibilities of the University, may be agreed upon. It is understood that such consultation of the inventor with University authorities shall be voluntary in the absence of prior agreement to the contrary, and that the right of the inventor to his invention shall not be prejudiced thereby.[17]

The College of Medicine at the University is guided by this policy and, with a view to discouraging the acquisition of patents, the medical college committee has in at least one instance recommended, after a careful study, that the individual drop his plans to obtain a patent. In general, the right of absolute ownership by a faculty member or student or other person connected with the teaching and research staffs of the University, of his own inventions or discoveries, whether or not made while using the regular facilities of the University, and the right of such persons to apply for, hold and dispose of patents are recognized as indefeasible. Exception is made in the event that the invention or discovery was made as a direct result of a specific research project sponsored and financed by the University or by the University of Cincinnati Research Foundation or by other agencies outside of the University, under a contract with the person concerned, specifying the abrogation of those rights as to that specific project. The facilities of the Research Foundation are available, both to the University and to the individual inventor, for the management of any patents that are taken out.

[14] Minutes of the Board of Permanent Officers of the School of Medicine, Yale University, New Haven, March 25, 1935.

[15] Bulletin of St. Louis University, School of Medicine, July, 1931.

[16] Minutes of the Advisory Board of the Medical Faculty, Johns Hopkins University, Baltimore, 1933.

[17] By-Laws and Regulations of the Board of Directors, University of Cincinnati, pp. 30-32.

The College of Physicians and Surgeons at Columbia University observes the policy,[18] established in 1930, that no member of the faculty or staff of the College should take out a patent on any medicinal, therapeutic or health substance or process, unless required to do so under the terms of a contract with the government or other outside sponsor. This policy differs from the general university policy,[19] which provides that in other divisions of the University patents may be obtained through University Patents, Incorporated, a patent-holding agency wholly owned by the University. This agency in turn assigns the patents to Research Corporation for management under an agreement with that organization. The only patent held by any one in the medical faculty is one on vitamin D, obtained by Dr. Theodore F. Zucker in 1924 under an old arrangement with University Patents, Incorporated. The question of patents has been discussed from time to time by the staff of the College of Physicians and Surgeons, always with the same conclusion: that while research is a prominent part of the program of the College, there have been enough unhappy experiences with patents to make the staff unanimous in the opinion that they should not get involved with the problem.

Although procedurally in effect since 1931, a definitive policy[20] with respect to patents on inventions and discoveries, particularly those with medical or public health implications, was not formally adopted by the Trustees of the University of Pennsylvania until 1941. That policy is the result of extended studies by both the faculty and trustees, during which a committee of the faculty went on record in 1933 with the following resolution[21]:

> That inasmuch as the University of Pennsylvania, like other similar institutions, is dedicated to education and the increase of knowledge in many fields, it is and should be the policy of the University that any discoveries, inventions or improvements made by it, through the members of its faculties or otherwise, which result, in the field of medicine in the alleviation of human suffering, or in the field of science in promoting in any way the welfare of humanity, should not be restricted by the University, but should be announced to the world so that such benefits may be freely enjoyed by all, and without pecuniary profit either to the University or to any one in its service. The University does not consider it necessary to call upon those in its service to execute formal agreements with it covering the situation, as is the cases in business enterprises, as it is confidently believed that the foregoing principles constitute the incentive and inspiration for their efforts.
>
> That nothing contained in the foregoing resolution shall prevent the University taking out patents at any time in order to protect an investigation prior to the completion thereof, any such procedure to be subject, however, to the principles above set forth in regard to the results of such investigation, when completed, being dedicated to the use of the public without pecuniary profit to the University or to the investigator, and this Committee will authorize the application for such a patent upon consideration of the facts submitted to it in any instance, and when in its best judgment such protection is necessary or advisable for any particular line of investigation.

The Trustees have declared it to be the policy of the University of Pennsylvania that any invention or discovery which may in any manner affect the public health, such as a new drug, process or apparatus intended primarily for medical or surgical use, shall not be patented for profit, either by individuals in the employ of the University or by the University itself. In order to prevent the capitalization and exploitation by others of any such discoveries or inventions and in order to protect the public, it may, however, from time to time be considered advisable to patent such inventions or discoveries with the sole intention of protection without profit. It is felt that this policy, which stipulates that neither the University nor the inventor shall receive profit from an invention or discovery in the medical field, removes the profit motive from medical investigation. In the case of sponsored research it need give nothing more than a head start on his competitors to the financial supporter of the project and leaves the University in the position of being able to obstruct efforts to exploit the public.

It is the general policy of the Medical Branch of the University of Texas, which is somewhat at variance with the patent policy[22] observed in the other units of the University, to allow members of the staff to make their own arrangements with regard to patents which may result from their research work. The Medical Branch, which includes the School of Medicine will not accept grants from foundations or commercial concerns for the support of research which carry any restrictions regarding patents or any other detail of the research work, apart from its general objective. There is a general understanding that, if a patentable process develops, the person concerned may seek the aid of an outside research foundation or patent management agency, such as Research Corporation, if he so desires. On the other hand, he is free to make patent arrangements with commercial concerns, with respect both to obtaining the patent and to administering it. It is also understood that, if a patent is obtained by a person as a result of research in one of the Medical Branch laboratories and royalties are involved, a proportion of the royalties shall be allocated to meet research expenses in the laboratory concerned. However, this principle is followed on an individual basis.

The Medical College of Alabama does not permit patents to be taken out on discoveries of any drugs therapeutic agents or appliances by members of the faculty of the school. In this respect the policy is generally applicable throughout the University of Alabama, of which the College is a division. Under the general university patent policy, provision is made for the handling of other types of discoveries and inventions through a University Patent Committee. In the event that a member of the faculty of any division of the University makes an invention which is patentable, the University waives all claim to a share in the royalties unless the University has made a substantial contribution in institutional time, money or facilities toward the production of the invention. If the University's contribution is $200 or less, the inventor is under obligation to reimburse the University for such contribution if he derives sufficient profits from the invention to do so, even though the patent rights remain the sole property of the inventor. If the University's contribution is in excess of $200, the invention becomes the property of the University and a percentage of the net profits derived from the sale or exploitation of the invention is allotted to the inventor.

[22] Patent Policy of the University of Texas (adopted by the Board of Regents on March 24 1945)

[23] Regulations of the University of Arkansas, Sect. 31.

GENERAL UNIVERSITY POLICIES

The patent policy of the University of Arkansas School of Medicine does not differ from that of the University,[23] which was adopted in 1945. In formulating that policy the University recognized that it has a responsibility to the state for discoveries and inventions made by members of the staff while engaged in research work as a regular part of their University duties. Such inventions and discoveries, including those which may have commercial application or should be patented in the public interest, are controlled by the University through a Committee on Patents which makes an equitable division of any royalties or profits that may be derived from their sale or licensing arrangements. The adoption of the general university policy was the result of the only experience which the University has had with the patent problem, when a member of the medical faculty developed a new method of producing xanthopterin which was thought to have commercial value but which eventually was not patented.

The University of California has a general university patent policy,[24] adopted in 1943, which applies to all employees of the University, including those in the Medical School. All matters relating to patents in which the University is in any way concerned are administered by a University Board of Patents which has full powers, subject to approval by the Regents of the University, to examine the merits of each potentially patentable project, to recommend the action to be taken, to facilitate patent applications, to protect both the University and the inventor, to arrive at an equitable determination of the rights of all concerned, to accept assignment of patent rights and to administer them in accordance with the best interests of the University, the inventor and the public. Assignment to the Regents of whatever rights the inventor or discoverer may possess in a patent or appointment of the Board as agent of the inventor or discoverer is optional on the part of the faculty member or employee. Any net income accruing to the Regents is devoted, first, to promotion of research within the University and, second, to general university purposes.

In dealing with discoveries and inventions in the medical and pharmaceutic fields the Division of Biological Sciences at the University of Chicago, in which is included the School of Medicine, is governed by the general patent policy[25] of the University as adopted by its Board of Trustees and incorporated in the statutes of the University:

> The University of Chicago's basic policies include complete freedom of research and the free, unrestricted dissemination of information. In view of these policies, the University will not profit financially from research by means of patents, royalties, or licensing agreements. Members of the staff will not be permitted to receive direct or indirect financial returns from patents based on work performed during the period of their employment by the University, or to make arrangements for such returns which take effect after such period. The University will coöperate with industrial organizations by conducting fundamental research projects financed by grants from such organizations and will make research reports to the grantors, [illegible] of the results. The University will not permit its name or the names of its investigators to be used in advertising.

The Division of Biological Sciences had been operating essentially under this policy for several years before the official university policy was adopted in 1943. It was applied in the fields of biology and medicine before that time because of the belief that income through patent royalties should not accrue to the University or its staff from discoveries which have a bearing on the prevention or treatment of disease or the preservation of health. It is recognized, of course, that the patenting of some discoveries may be necessary or desirable for the protection of the public interest or for other reasons. Depending on circumstances the inventor may, with University approval, take out a patent and dispose of it by assignment to a person, firm or organization who has supplied the funds for support of research or to some agency independent of the University, such as Research Corporation. This is done by free assignment, without financial return to the University or the inventor.

The patent policy of the University of Illinois College of Medicine is identical with that of the University,[26] but as a general practice applications for patents are discouraged in the College, although a patent may be sought for the purpose of controlling the quality of a patentable product. Under the general university policy the principle is recognized that the results of experimental work carried on by or under the direction of the scientific or teaching staffs of the University, the expenses of which are paid from university funds or from funds under the control of the University, belong to the University and to the public, and should be used and controlled in ways to produce the greatest benefit to the University and to the public. The practice is, therefore followed of taking out patents on valuable discoveries and inventions which may be expected to have a basic relation to other discoveries or inventions of commercial importance. The patents are assigned to the Board of Trustees of the University for a nominal consideration and the Board administers the rights under the patents in ways to suit the conditions, dedicating the patent to the public or licensing its use. The facilities of the University of Illinois Foundation may be used in the commercial exploitation of the patent rights. The patentee is paid a share of any sum above a nominal royalty that may be received by the University.

Although the University of Kansas School of Medicine has not had any experience with patent problems, the School would follow the general policy[27] of the University and utilize the facilities of the University of Kansas Research Foundation. Under that policy any one who believes that an invention resulting from a research project sponsored by the University should be patented would present the matter to a faculty advisory committee, appointed by the Chancellor of the University, which would determine whether or not the Foundation should prosecute a patent application on the invention. In the event that any sum over and above the cost of obtaining a patent should be received by the Foundation, a fair share of the profits (at least 15 per cent) would be paid to the patentee, and the remainder of the profits would be used to finance the activities of the Foundation and to sponsor further research in the University. In the case of cooperative research sponsored in part by an outside agency, the written contract between the University and the cooperating agency would include a statement that all the results, including inventions, belong to the University and would be so used and controlled as to produce the greatest benefit to the public. If all the costs are paid by an outside sponsor, he would be entitled to have all patents assigned to him, the University reserving only the right to publish all fundamental data of value to science and technology.

[24] [illegible] California, Aug. 15, 1943.

[25] Statutes, University of Chicago, p. 63.

[26] Patents on Discoveries and Inventions, University of Illinois Statutes 44, pp. 16-17.

[27] Minutes of the State Board of Regents, June 11, 1943.

The University of Louisville School of Medicine follows the general university patent policy,[28] adopted in 1935, which includes provisions covering both (1) the administration of patents and possible income from such patents and (2) the conditions which should attend inventions or discoveries made by members of the staff of the University. An Administrative Board of Patents, established by and subject to the direction and control of the Board of Trustees of the University, has authority "to accept for and on behalf of the University by assignment or otherwise, either directly or through trustees or holding corporations, patent applications, royalties, licenses, or gifts therein governing discoveries, inventions or processes, when produced by members of the staff of the University by use of University laboratories or otherwise." A patent assigned to the University is administered by the Board in such manner as it may determine, provided that if the patent is sold or royalty for its use is received, one half of the money thus realized by the University would be paid to the patentee and the other half assigned to the University.

A definite patent policy for the entire university, adopted by the Board of Regents of the University of Nebraska in 1946, applies to the College of Medicine as well. That policy was established for the purpose of stimulating inventive genius, encouraging the disclosure for the public benefit of discoveries and new inventions made at the University by its faculty personnel and employees, and defining the rights of the University in returns from resulting patents. The title to a patent on any discovery or invention belongs to the employee, and he is free to develop or handle it in any manner he sees fit, provided that when total net royalties or other compensations are less than $1,000, no payment to the University is required, but when they amount to more than $1,000 and less than $5,000 per year, 10 per cent of the excess of such royalties or other compensations above the sum of $1,000 and less than $5,000 shall be paid to the University, and when they amount to more than $5,000 per year, the royalty to be paid to the University shall be 10 per cent on all the amount above $1,000 and less than $5,000 and 20 per cent on all amounts above $5,000. In the absence of a specific contract to the contrary, the provisions of the policy are incorporated in the employment agreements of faculty personnel and other employees of the University.

The Stanford University School of Medicine follows the general university policy in the handling of patentable results of scientific research in relation to medical and pharmaceutic discoveries. Whenever any member of the staff or other person making use of the laboratories or other facilities of the University makes a discovery or invention, or otherwise believes a valuable invention may result from his research, he is required to communicate that fact to the executive head of his department or school. The matter is then referred to the Patent Committee of the University, which examines into the nature of the discovery or invention and, if in the opinion of the committee it should be protected by patenting, recommends its assignment to the University. The University reserves the right, in its discretion, to manage and exploit all patents assigned to it in the public interest and in such manner as it considers consistent with the best interests of the public and the University. Ten per cent of any gross royalties or other revenues received by the University is paid to the patentee, except when the patentee is a member of an organization whose ethics deny the right of its members to receive such revenues or when the patentee is employed or assigned to work on a specific investigation. After all proper expenses have been met, the remainder is appropriated to the department or school in which the discovery was made for research in the same or related fields. Any revenue in excess of the reasonable needs of such research is placed in a patent pool fund for allocation to the support of other research by the Board of Trustees on recommendation of the President of the University.

The University of Utah Medical School follows the general policy of the University adopted in 1944, which provides that patents should be administered in such a way that the public receives the maximum benefit. In order that the patents may be put to work and developments under them made available to the public, all patent matters, including those arising in the Medical School, are handled by a University Patent Committee. It is believed that the public can best be benefited, in some instances, by actual transfer of patent ownership from the University to supporting companies or agencies and, in other instances, through licensing arrangements by which the control is left with the University. Either exclusive or nonexclusive licenses may be issued, depending on the circumstances. Ten per cent of the net royalties or other revenues received from patents by the University are paid to the inventor, except in cases in which some other division of the income is considered more appropriate. The remainder, after meeting all proper expenses, is allocated to the University Research Fund. The University feels that, in the handling of patents, it should be activated by a desire to benefit the largest number of persons in the most economical and effective way.

GENERALLY ACCEPTED PRACTICES

Certain of the medical schools, affiliated with universities which do not have formal patent policies, follow the general practices of those universities in permitting faculty members and other employees to exercise their own judgment in handling the patentable results of their research efforts but encourage them to utilize the facilities of special research foundations, independently incorporated but closely related to the institutions. These foundations, such as the Cornell Research Foundation, the University of Tennessee Research Corporation and the Wisconsin Alumni Research Foundation, are available to act as patent management agents for the universities concerned, their medical schools, and the individual inventors, through the voluntary assignment of patent rights.

As in the rest of the University, patent matters arising in the Cornell University Medical College are handled through the Cornell Research Foundation. The Foundation was established in 1931 with "power to act in all matters concerned with the acceptance, promotion, management, and protection of all patents in which Cornell University may be interested, with power to take or acquire assignments of patents, to permit commercial development of the same through sales, licenses, or the like, and to receive gifts and devices which may be offered in aid of research through the activities of such Foundation."[29] Since 1945 it has been the general policy of the University in making contracts with grantors or sponsors of research programs not to agree to give the grantor or sponsor more than a nonexclusive license under any patents that may result from the research. However, in cases in which the grantor or sponsor pays all expenses of the research, including overhead, the University may in exceptional cases agree to grant an exclusive license or to assign all rights in the patent to him.

---

[28] Excerpts from the minutes of the Board of Trustees, University of Louisville, September 25, 1935

Patents resulting from research in the University of Tennessee College of Medicine are handled through the University of Tennessee Research Corporation founded by the University in 1935. The main purposes of the Corporation are the holding of title to patents issued on research work by members of the University staff and the promotion of the use of the inventions and discoveries covered by these patents.[30] The University has no formalized patent policy, but all members of the faculty, including those in the College of Medicine, are encouraged to use the facilities of the Corporation to relieve them from all concern with the administrative and commercial aspects of patent management. It is believed that the major benefits come from the fact that the Corporation serves as a means of protecting results of research from selfish exploitation or suppression by interests which might gain control in some way. Also, the Corporation provides a link between the laboratory and the field of practical application.

In the University of Wisconsin Medical School, as in the rest of the University, the individual research worker is privileged to handle the patentable results of his scientific research in any manner that he sees fit. Some have assigned their inventions and discoveries to the Wisconsin Alumni Research Foundation as their agent and have permitted such profits as have accrued from these discoveries to be compounded through this agency. The Foundation was organized in 1925 "to promote, encourage, and aid scientific investigations and research at the University and to assist in providing the means and machinery by which the scientific discoveries and inventions of the staff may be developed and patented, and the public and commercial uses thereof determined; and by which such utilization may be made of such discoveries and inventions and patent rights as may tend to stimulate and promote and provide funds for further scientific investigation and research within said University."[31] When patentable ideas developed by university faculty members are voluntarily turned over to the Foundation, efforts are made to commercialize them, with the understanding that after the cost of development has been recouped, any remaining moneys are to be employed in the support of research in the natural sciences. With respect to medical discoveries and inventions, the attitude is taken that patents should be secured if a lack of control in the use of the patented article might result in undue exploitation of the public, in lack of uniformity of standardization or in confusion of the public mind as to the inherent values of the product. In certain types of medical discoveries, the Foundation considers itself obligated to administer the patents without thought of any financial return other than that required to safeguard and control the proper use of the product and to provide funds for clinical and scientific work in connection with the discovery.[32]

The College of Medicine of the Ohio State University follows the general practice of the University in using the facilities of the Ohio State University Research Foundation in the handling of patent matters, as well as sponsored research projects. Except in connection with research projects conducted under contracts made by the Foundation, the University has no formalized patent policy other than the provisions in the state statutes that all rights accruing from patentable discoveries resulting from investigations carried out in the University laboratories with the use of University facilities are the property of the University and that the University may assign and transfer its rights or grant licenses as desired. It has been the general practice for the University not to apply for patents in the field of medical research, but rather to disseminate the results of such work in the widest possible way for the greatest public benefit. Patents in this field would be applied for only in those special cases in which the members of the medical profession felt that it was necessary for the protection or welfare of the public.

At Duke University it has been the practice in the School of Medicine since 1937 to assign patents to nonprofit research committees named by the President of the University and to use the revenue from royalties for the support of further research work at the School. Essentially, the plan provides for handling each case on its merits and in a manner that seems best, the procedure generally followed throughout the University. If an investigator has something that should be patented, the legal department of the University draws up an agreement for the assignment of the patent. Any royalties received are deposited to the credit of a special fund and expenditures from that account are made on the written recommendation of the research committee but not for the benefit of any individual person.

The University of Minnesota Medical School follows the general practice of the University, under which all patentable discoveries are referred to a University Committee on Patents, established in 1938. That committee is authorized to receive and consider applications from staff members desiring to secure patents, at University expense and with University control and participation in profits, and recommends to the Board of Regents agreements with staff members for the assignment of patents and arrangements covering the licensing of the patents. One fourth of all royalties are given to the staff member when the patent is in the general field of his employment, and one half when it is outside that general field and University funds and facilities were not used in the development of the patent.

It is the consensus of the executive faculty of the School of Medicine of the Tulane University of Louisiana that professional standards would be violated if either the inventor or the School derived financial profits from patentable devices and processes. Several years ago, when a faculty member who had developed an instrument sought advice on patent procedure, it was decided that neither he nor the School should hold the patent or enter into any arrangement through which there would be a monetary return. Accordingly, the specifications of the instrument were turned over to a reputable manufacturer under an agreement that the price would be held to a minimum. One item in the agreement, under which the inventor relinquished all claim to royalties, was that a reduction corresponding to potential royalties be made in the cost to the buyer. Three instruments have been developed by this faculty member and all three have been handled in the same manner, each with a different manufacturer. The precaution regarding cost of the manufactured instrument was taken in the public interest. The University itself, exclusive of the School of Medicine, has no patent policy except in relation to grants awarded through the University Council on Research. It is understood that, if a project supported by a grant from the Council yields any income, whether from patentable devices or processes or as royalties on books, such income up to the amount of the grant is to be returned to the research fund.

---

[29] Policy of the Cornell Research Foundation, as contained in the minutes of the Board of Trustees, Cornell University, June 24, 1946.

[30] Charter of Incorporation, University of Tennessee Research Corporation.

[31] A Decade of Service, Wisconsin Alumni Research Foundation, 1935, p. 1.

[32] A Decade of Service, Wisconsin Alumni Research Foundation, 1935, p. 5.

The Washington University School of Medicine has for many years observed the general policy that no pecuniary profit should accrue to any person or stock corporation from a patent on a scientific discovery originating in the School. For the protection of the public a patent may on occasion be taken out, provided the rights are assigned to some nonprofit organization Any profits that might accrue from such a patent would be used for the support of scientific education and research, and not for any other purpose. The University does not have any formal over-all patent policy, although the question has been under study for some time, and the policy of the School of Medicine differs materially from the practices currently followed in the rest of the University, especially in the School of Engineering.

It has been the general practice of Indiana University and of its School of Medicine, neither of which has a formal patent policy although the question has been under study for some time and considerable work has been done on the formulation of a definite statement of policy, not to permit applications on the products of individual or school-supported research. In 1936 a separately incorporated body, the Indiana University Foundation, was established to finance research, handle patents, aid the University in undertakings for which funds were not otherwise available and generally perform such functions as the University, being a state institution, could not do for itself. Many of the contracts made by the University in connection with research grants contain clauses relative to the ownership of the inventions that may develop as a result of the grant. In most of these contracts the University has the option of retaining ownership of the invention in its own name or in the name of the Indiana University Foundation. Some also provide that the donor have a royalty-free license for the manufacture and use of the discovery Members of the faculty have also been permitted to sign contracts with commercial organizations furnishing financial support and to agree in the contract as to the patent rights, with the returns from royalties going directly to the research worker in some instances. It is felt that this plan is not objectionable and is broad enough to encourage substantial support of research studies by commercial organizations and that a stricter policy "would undoubtedly remove considerable support of research programs and would deny medical and graduate students the opportunity of gaining valuable research experience."

While deciding each case on its individual merits, the Western Reserve University School of Medicine follows, as a general rule, the practice of not patenting discoveries in the field of medicine. However, where it seems necessary in the public interest, patents may be taken out on a nonprofit basis. When such patents result from research financed by a commercial concern, the sponsoring concern is given a nonexclusive royalty-free license in its field for a limited time before other firms are granted licenses.

The University of Virginia School of Medicine is in general opposed to the patenting of inventions or discoveries by members of the medical faculty. In the only instance in which the question has arisen during the past ten years the inventor of a minor surgical instrument was advised against taking steps toward securing a patent.

At Temple University it is the feeling of the management, as well as the faculty of the Medical School, that patents should not be sought but that the worth while results of their research work should be given freely to the profession.

EACH CASE HANDLED INDIVIDUALLY

At the University of Rochester School of Medicine and Dentistry it is felt that it is usually best to resolve each particular problem as it arises, with a view to protecting the good name of the University and doing everything possible to obviate any criticism that the cost of the patented product to the ultimate consumer or patient was increased because of financial benefit to the University or the inventor.

Although the University of Colorado has no written patent policy, its School of Medicine has in the past followed the unwritten policy of patenting nothing and publishing freely the results of all research and development. It is likely that, in recognition of the attitude of the medical faculty, provision will be made for the licensing of certain patents on a nonexclusive royalty-free basis, as part of a general university policy which is presently under consideration.

At several of the other medical schools each case is handled individually as it arises and, in the absence of a general university or special medical school policy, an attempt is made to work out an equitable solution in each instance. This is the situation in the schools of medicine at Georgetown, George Washington and New York Universities. At the New York University College of Medicine, in accordance with a general procedure followed throughout the University, final action is taken only after consultation with the dean of the executive faculty and the secretary of the University.

The practice is followed at Vanderbilt University, both in its School of Medicine and in the University generally, of bringing inventions and other apparently patentable material to the attention of a University Patent Committee which reviews each case individually and recommends to the administration of the University the specific action and procedure for each case.

Neither the University of Michigan Medical School nor the University as a whole has a clearly defined patent policy, except with respect to contractual research conducted in or through the Department of Engineering Research. Outside of such research projects, each case is decided in the light of its own circumstance.

In the one instance in which a product of research in the University of Pittsburgh School of Medicine was found to have commercial value, a patent was obtained and the trustees of the University accepted the assignment of the patent rights, the income from royalties to be used to support further research without financial gain to the inventor personally.

While the University of Georgia does not have any specific patent policy, proceeds on the sale of several inventions made by members of the medical faculty are added to the budget for equipment and supplies for research in two departments of the School of Medicine.

Neither the Syracuse University College of Medicine nor the University itself has formulated a policy in regard to the handling of patentable results of scientific research. However, in connection with the activities of the recently organized Syracuse University Institute of Industrial Research, an industrial corporation for which research is conducted at the University in cooperation with the Institute will retain patent rights growing out of such research.

At the University of Maryland, which is at present working on a university-wide patent policy, which will apply to the School of Medicine as well, it is contemplated that the recently created State Institute for Industrial Research affiliated with the University will act as a patent management agency and will recognize the inventors among the faculty through royalty payments or some share in the income from patents.

A number of the other medical schools, associated with universities and colleges which do not have formal patent policies, have not had any occasion to develop separate policies or as yet to crystallize their thinking along these lines. The patent problem has never arisen at the medical schools of Baylor, Emory, Louisiana State and Marquette Universities, of the Universities of Oklahoma and Oregon, and of Tufts College and at the Bowman Gray School of Medicine, a division of Wake Forest College.

If the question should arise, the Emory University School of Medicine would follow whatever general university policy is adopted as the result of a current study being made by a committee of the university faculty. Should it become necessary to establish a patent policy for the University of Oregon Medical School, which at present has none, it would be developed in collaboration with the State Board of Higher Education as an over-all policy for the other units of the University as well as Oregon State College, which are all under the same governing board.

At Northwestern University a special trustee committee is currently giving consideration to a general university patent policy which will include medical patents and problems related to the Medical School. A similar situation exists at Loyola University, where the formulation of a university patent policy, that will apply to its School of Medicine as well, is in the discussion stage. A university committee is in the process of setting up such a policy for the University of Vermont, which does not have a definitely formulated patent policy at present, either for the University itself or for its College of Medicine. The same is true at the University of Southern California, where the subject has been under consideration for some time, both on a university-wide basis and with respect to the School of Medicine.

In the other seven university-affiliated medical schools no definite policies for the handling of the patentable results of scientific research have as yet been established, either for the universities themselves or for the medical schools, although the question has been under discussion from time to time at most of them. Included in this group are Boston, Creighton, Howard and Wayne Universities, the State University of Iowa, the University of Buffalo and the Albany Medical College which is embraced with Union College in the Union University system.

INDEPENDENT MEDICAL SCHOOLS

Of the ten independent medical colleges on the approved list of the American Medical Association only two have definite patent policies, although several of the others follow informal policies or general practices. Two of them—the College of Medical Evangelists and Hahnemann Medical College—handle patent matters through separately incorporated nonprofit foundations. The question of patents has arisen at most of the other schools and has been under discussion from time to time without any definite action on policy. On the occasions when the problem has been acute, each case has been settled on its individual merits. At the present time most of these independent medical colleges are giving consideration to the formulation of definitive policies or the revision of existing practices.

At Southwestern Medical College, under a policy adopted in 1945 by the Trustees of the Southwestern Medical Foundation, the corporate body under which the College operates, any salaried faculty member who desires to take out a patent on an original discovery has the option of either dedicating it to the public or assigning it to the trustees of the Foundation without consideration of personal profit. It is contemplated that the Foundation will not grant exclusive licenses on any patentable discoveries assigned to it. The policy has been under study with a view to having certain of the royalties returned to the College, but so far the trustees have taken no action. The question of whether the research worker making the original discovery should receive any benefit from the royalties is also under discussion.

Meharry Medical College has adopted a definite policy concerning patents in connection with a recently initiated research program and the establishment of the Meharry Biological Research Fund, under the direction and control of a special research committee, for the stimulation and development of research at the institution. Under this policy the discoverer receives a percentage (not less than 10 per cent) of the profit from any patent, the exact amount depending on the over-all cost of development. The balance, after the Research Fund has been reimbursed for its investment in the investigation, is held in the Fund for use in the support of further research or for allocation to the College for general educational purposes. The College has not as yet had any experience with patents and does not anticipate in the foreseeable future any patentable products from research now under way.

The Woman's Medical College of Pennsylvania has an informal policy which opposes the patenting, either by the College or by a member of the staff, of any medical appliance or any medical preparation. This is merely an expression of opinion by the faculty; no formal resolution has ever been adopted by the faculty or administration of the College.

The College of Medical Evangelists has no written policy regarding patents resulting from scientific research within the institution by members of the staff, but there is a general understanding that full-time employees should not profit personally from medical discoveries. In a number of instances patentable instruments developed by members of the staff have been turned over to the Alumni Research Foundation of the College of Medical Evangelists, a nonprofit corporation organized in 1943 primarily for the purpose of raising funds to aid the College in its research program.

In a reorganization which is now under way at Hahnemann Medical College some thought has been given to patent matters and the revision of existing practices. The College has had since 1939 a separately incorporated Hahnemann Research Foundation, organized to accept the assignment of patents resulting from research done under its auspices and to acquire patents by voluntary assignment or gift. In the disbursement of the net income from patents a predetermined share is given to the inventor. The Foundation handles all relations with industrial organizations involving patents, but the College also has, separate and distinct from the Foundation, a research committee made up of members of the college council (seventeen members of the major faculty) to consider, act on and approve all matters relative to research. Any research problems, including those which may involve patents, that may arise within the college faculty are referred to this committee for study. All questions of law and legal relations are within the sole jurisdiction of the trustees of the College.

While the New York Medical College has no fixed patent policy, it is the present practice, when accepting research grants from outside sponsors, to refer problems which may involve patents to their legal department before the contracts are approved or disapproved by the Research Committee of the College. Generally commercial firms have been protected in their patent rights.

The other four independent medical colleges have no established patent policies, although at Jefferson Medical College the question is at present under study by the board of trustees. At the Long Island College of Medicine the problem has been discussed from time to time, and at the Medical College of Virginia possible policies have been suggested at various times, but without any definite action at either institution. The Medical College of the State of South Carolina has as yet developed no policy for handling the results of scientific research conducted at the College.

SUMMARY

The patent question is currently under review at more than half of the seventy approved medical schools, at a number of them as part of new or revised general university policies. Obviously the patent problem is not a settled one in the medical schools and a wide difference of opinion exists among their faculty members as to the ethics of patenting a medical discovery, but in those schools, as in educational institutions generally, the question is being given thoughtful consideration at the present time. Much of the stimulation for the establishment of definitive patent policies stems from problems growing out of research projects sponsored by outside agencies, especially commercial firms. Frequently such practices as are currently followed are concerned solely or mainly with the results of scientific research conducted under grants from these outside sponsors.

At present there is a wide diversity of practice among educational institutions—and even at the same institution—in handling patentable discoveries and inventions growing out of scientific research. There is no common pattern of policy statement, administrative procedure, recognition of the inventor, determination of equities, assignment requirement, patent management plan, distribution of proceeds or protection of the public interest. Nor is there any convenient grouping according to type or size of institution, complexity of university organization or kinds of research undertaken. Existing practices vary from strictly drawn patent policies to laissez-faire attitudes and even an unwillingness to become concerned with patents.

Some institutions follow a hands-off policy, leaving to the individual inventor the responsibility for determining what disposition is to be made of the product of his research efforts. Others take the position that the institution has an interest in all research activity on the campus and have established formal patent policies or follow generally accepted practices for handling any patentable discoveries that may result. Still others observe a definite policy of not having a patent policy. A great many, however, have given little or no consideration to the patent problem, despite the increasing volume of scientific investigation on the campus.

Through the years certain institutions, faced with immediate situations, have formulated more or less definitive patent policies. Yet less than forty such policies have been formally adopted thus far, more than half of them during the past six years. At a number of other institutions practices and procedures are being currently followed which, though not definitely formalized, are generally accepted as applicable to research activities throughout the institution. A few have adopted special policies or recognize general practices for dealing with those results of scientific investigation that affect public or private health. Others have developed policies and practices only with respect to sponsored research.

Many of the formalized policies and most of the prevailing practices are currently under review to meet changing postwar conditions and current considerations in the institutions. The need at this time for critical examination of the whole question of what to do with the patentable products of research is well recognized. At a number of institutions, many of which have not previously had any patent policy, faculty and trustee committees are currently studying the question, with a view to formulating new, or revising existing, policies.

At many institutions each case is decided on its merits in accordance with a general policy or, in the absence of such a policy, by agreement among the parties concerned. A few still feel that they discharge their responsibility by merely publishing the results of investigations or by securing patents and dedicating them to the public. Others accept full responsibility for obtaining patents and administering the patent rights in the public interest. Many exercise control over the patents by issuing licenses and accepting royalty payments, either directly or through agents whom they have designated to manage their patents.

Some recognize the rights and interests of the inventor and share the proceeds with him, either under a prior contractual arrangement or by mutual agreement, but there is no uniformity in the division of the financial return from patents between the inventor and the institution. Even in those instances in which the proportion to be given the inventor is specified in accordance with a general policy, there is a wide variation among institutions in the amount allotted to the inventor. In other institutions the inventor's share is determined in each case after consideration by a special faculty or administrative committee. A few institutions include patent provisions in their contracts of employment, in some instances for all faculty members, but more often limited to members of the staff whose entire or major responsibility is research, especially contractual research.

At most institutions the compulsory assignment of patent rights is not considered desirable, except when necessary in connection with cooperative or sponsored research. Voluntary assignment is preferred and in many institutions is encouraged and facilitated through procedures and special machinery for handling patents set up within the institution. In many instances the services of an outside organization closely related to the institution and under agreement to act as its patent management agent are employed.

Patent management is a complicated business and is expensive. It requires a high degree of legal competence, administrative astuteness and promotional zeal—a combination of talent not always readily available in an educational institution. The patent search is a specialized technical service. The preparation and processing of patent applications are exacting work for legal counsel. The administration of patent rights demands careful attention to intricate details and constant watch for infringement and interference. The exploitation and disposal of patents, through sale and licensing agreements, require salesmanship of a high order.

It is natural, therefore, that most educational institutions make every effort to avoid becoming directly involved in the intricate legal and commercial aspects of patent management. Some endeavor to accomplish this by adopting a hands-off policy and refusing to handle patents. Others, for legal or fiscal reasons, use the facilities of separately incorporated patent management foundations, independent of, but closely allied to, the institutions by the terms of their charters and by the membership of trustees, administrative officers and faculty on the foundations' boards of directors. Still others have entered into agreements with Research Corporation, an independent nonprofit patent management foundation, to handle patentable discoveries in their behalf, with full protection of their interests and those of the inventors and the public.

A few attempt to handle patents as a part of the routine duties of already established administrative units, such as the comptroller's or business office. Others handle them through specially designated committees responsible directly to the administration or to the trustees of the university. A number have faculty committees on patents, which exist primarily for the purpose of insuring that pertinent institutional regulations are observed. Often these committees serve as advisory bodies and are charged with recommending action on matters that range from the desirability of taking out a patent to the determination of equities.

There are at least three distinct equities or interests involved in patentable discoveries or inventions resulting from scientific research in an educational institution: the inventor or inventors, the institution and the general public; to which must be added a fourth, the sponsor or supporter of the research, in the case of sponsored or cooperative research. When further developmental work is necessary, a fifth interest may be involved, although frequently it is the same as the sponsor or supporter of the original research.

The recognition and protection of these several and diverse interests naturally complicate any individual situation. Self interest, personal rights, professional ethics, institutional policies, employer-employee relations, academic freedom, contractual relations, patent law, business practices, commercial competition and the variables in individual cases are some of the elements that contribute to the problem. Nevertheless, to be equitable and effective a patent policy must provide for such recognition and protection, placing the responsibility where it can be best discharged, most expeditiously and with the minimum of burden on the regular administrative and teaching staffs of the educational institution.

While there is at present a great variation of practice among educational institutions generally and among medical schools, efforts are being made by many of them to formulate definitive research and patent policies. This is a healthy sign and is to be encouraged and facilitated. Especially so far as medical discoveries are concerned, protection of the public interest, as well as the interests of the institutions themselves and the inventors, requires that existing differences be resolved and that some agreement be reached among all the parties concerned.

If the proper safeguards are established, our universities and particularly our professional and technologic schools can contribute, even more extensively than they have in the past, to the progress of science through the most effective utilization of their research facilities and the present short supply of scientific and technical personnel.

VALUE OF CONSERVATIVE MANAGEMENT IN CERVICOBRACHIAL PAIN

G. E. HAGGART, M.D.

Boston

The complaint of pain in the neck, shoulders and extending into the arm is of relatively frequent occurrence. It is believed that the cause or combination of causes which can bring on these symptoms is not widely understood and, therefore, it is the purpose of this paper to review the various etiologic factors that may produce cervicobrachial pain, and in particular to stress the favorable results obtained by conservative treatment.

To avoid confusion, I have arbitrarily omitted consideration of patients with symptoms resulting from pathologic changes in the shoulder such as subacromial bursitis or a tear in the musculotendinous cuff; i. e., conditions which do not cause interference with the neurovascular structures. I wish to emphasize, however, agreement with Freiberg [1] that lesions of the shoulder girdle may initiate cervicobrachial pain by concomitant diffuse muscle spasm accompanying the lesion. Such pain may likewise follow voluntary splinting of the affected arm with depression of the painful shoulder, as so frequently occurs after trauma.

LITERATURE

Under a wide variation in titles the literature contains

From the Department of Orthopedic Surgery, the Lahey Clinic.

Read before the Section on Orthopedic Surgery at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

numerous references[2] to neuritic pains and vascular disturbances in the upper extremities. The greater number of these papers are concerned with reports on (1) cervical rib, beginning with the original article of Gruber,[3] and later reports of Adson and Coffey[4] and Patterson,[5] and (2) on the scalenus syndrome by Naffziger and Grant,[6] Ochsner, Gage and DeBakey.[7] That other causes exist was brought out by Wright[8] in describing the symptoms resulting from hyperabduction of the arm, and by Falconer and Weddell[9] in reporting the costoclavicular syndrome. Todd[10] has discussed the importance of posture in the cervical rib syndrome. Spurling and Scoville,[11] Michelsen and Mixter[12] described protrusions of intervertebral disks in the cervical portion of the spine. Walshe and associates[13] presented a detailed analysis of pressure effects associated with not only cervical rib but "normal" first rib, as well as emphasizing, as have many writers, the significance of an alteration in the normal topographical relation of the thoracic cage to the shoulder girdle.

DIFFERENTIAL DIAGNOSIS

It is most important to obtain a detailed history with particular reference to the onset of symptoms, distribution of pain and, if present, the degree of vascular change. This is followed by a neurologic and orthopedic examination, including roentgenograms of the cervical portion of the spine.

The roentgenograms permit division of the patients into two groups: (*a*) those with structural abnormalities such as cervical rib, asymmetry and variation of the thoracic outlet and arthritis and (*b*) patients with negative or normal roentgenograms. It is understood that if protrusion of an intervertebral disk in the area of the cervical part of the spine is suspected, this is localized by myelogram study. It is likewise stressed that abnormalities in the roentgenogram are not necessarily the sole cause of complaint, since in the average patient seen these variations have been present for years without causing symptoms, but at least such anomalies are suspect.

Therefore, the diagnosis in patients with cervicobrachial pain, with or without vascular change, can be considered under the headings listed in table 1.

It is not within the scope of this paper to discuss the details of all these factors, as they have been considered in the literature. It is pertinent, however, to comment on some aspects of the diagnostic problem.

Observations on patients at the clinic have convinced me that the causal agent most commonly present in patients experiencing cervicobrachial pain is that here classified under postural defects; in other words, abnormal relationship of the shoulder girdle to the thoracic cage and its attached structures. This applies in both groups; that is, patients with and those without variations from normal anatomy as shown in the roentgenogram. It is believed that sagging and drooping of the shoulders exert tension on the brachial nerve roots and blood vessels, stretching the structures still more tightly over the upper edge of the thoracic outlet.

TABLE 1.—*Diagnosis in Patients with Cervicobrachial Pain*

Group A. Abnormalities Apparent in Roentgenogram
    Cervical rib
    Abnormal first rib
    Cervicodorsal scoliosis
    Asymmetry and variation in thoracic outlet
    Arthritis
    Protrusion of cervical disk shown by myelogram
Group B. Abnormalities Not Apparent in Roentgenogram
    Scalenus anticus syndrome
    Costoclavicular compression
    Hyperabduction syndrome
    Causalgia or sympathetic dystrophy
    Postural defects; i.e., abnormal relationship of shoulder to thoracic cage

Todd[14] reported that the relative position of the shoulder to the thorax is high in children but at puberty a gradual descent occurs to the adult position. This is more pronounced in the female, in whom the ultimate position of the shoulder is more sloping than in males. This author therefore suggested a relationship between the position of the shoulder and the greater incidence of symptoms of cervicobrachial pain in women and offered an explanation for the rarity before adolescence. Furthermore, as Jones[15] pointed out, when symptoms occur they are most commonly of nervous origin, since the lowest cord of the brachial plexus is more intimately related to a cervical rib, an abnormal first rib or a normal first rib than are the subclavian vessels.

The embryologic development and anatomy of the structures about the upper end of the thoracic cage were summarized by Patterson,[5] who observed that in quadrupeds and human embryos the blood vessels and nerves to the upper extremity, along with the ribs, come off more or less at right angles to the spinal column as the latter is carried parallel to the ground. But as man begins to assume the upright position the upper extremities pull downward parallel to the spine and the brachial plexus and subclavian vessels, on the outside of the thoracic cage, thus straddle the first rib, or if a cervical rib is present, pressure on these structures is increased (fig. 1).

Also, the thoracic cage in quadrupeds and human embryos is broader from front to back, whereas in adult man the cage is broader from side to side. This increased lateral diameter adds to the traction forces on the brachial plexus and subclavian vessels.

In regard to asymmetry and variation in the thoracic outlet, as pointed out by Walshe and associates,[13] in the presence of such anomaly, the thoracic outlet tends to be narrower on one side than on the other, different in outline on one side, and it is often higher on one side. Hence, the plane of the opening is abnormally tilted both in the transverse and anteroposterior directions. It therefore follows that there must be abnormalities in the insertion of the scalene muscles, which are homologues of the intercostal muscles. Furthermore, the raising and asymmetry of the thoracic outlet increase the possibility that maladjustments may occur between the nerve roots and bones as well as the associated muscular abnormalities which tend to contribute to abnormal conditions and hence symptoms. Likewise, it is evident that a stretching effect on the lower brachial trunks of the plexus is influenced appreciably by diminished obliquity of the thoracic outlet, which effect would be exaggerated in the case of cervical rib.

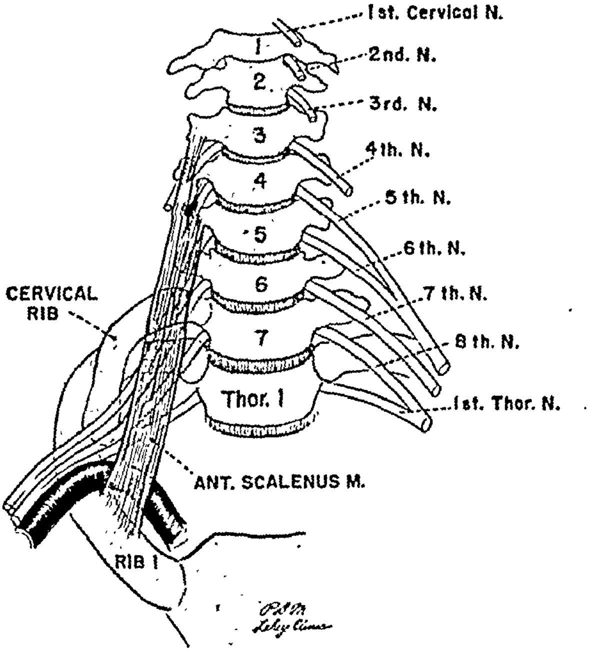

Fig. 1.—Illustrating the relation of cervical nerves to cervical vertebrae as well as the relationship of the plexus and subclavian vessels to the first rib, a cervical rib and the anterior scalenus muscle

In the growth of the clavicle, obtaining its full development around 20 to 25 years of age, one would then expect a full stretching effect on the lower nerve roots of the plexus to be apparent at that time. If the clavicle projects up and outward, as frequently occurs in men, there will be less constant stretching of the lower brachial nerve trunks than if it projects down and outward as is the case in women. Also, in women there is greater movement of the upper part of the chest than in men, and hence more likelihood that the nerve trunk may be interfered with by the first rib, even if that be normal, and this is more pronounced if cervical ribs are present.

With this general background it is to be borne in mind that the clavicle may be an important factor causing compression of the artery in the presence of an abnormal rib and it probably plays a more significant role in the production of symptoms in the presence of an abnormal rib than is commonly realized, because the clavicle and the abnormal ribs together may constitute a vise in which the third part of the artery as well as the plexus is recurrently gripped. This hypothesis is also supported by the studies of Sampson, Saunders and Capp,[16] who investigated normal and abnormal venous patterns of the anterior chest wall. They concluded that prominent veins in this area were most commonly caused by compression and partial obstruction of the subclavian vein between the clavicle and first rib.

Degenerative arthritis of the cervical portion of the spine may be the cause for neuritic symptoms in the upper extremities, particularly when there is sufficient productive bone change to cause exostoses or hyperplastic bone to protrude posteriorly into the intervertebral foramina (as shown in figure 2). As emphasized by Nachlas,[17] "It is in their passage through the intervertebral foramina that the nerves are particularly subject to irritation." Furthermore, the posterior wall of this canal consists in greater part of capsule, so that when the latter is swollen or distended by intra-articular fluid there is an additional protrusion into the lumen and hence impingement on the nerve root. As this same author pointed out, within the relative protection of the intervertebral foramen the nerve structure is such that there is a particular susceptibility to irritation of the *sensory* neuron because in this area the posterior roots lose the protective myelin sheaths of the axons, while the motor fibers, on the other hand, enter the canal anteriorly, do not lose their sheaths and form a much smaller cable than the sensory root.

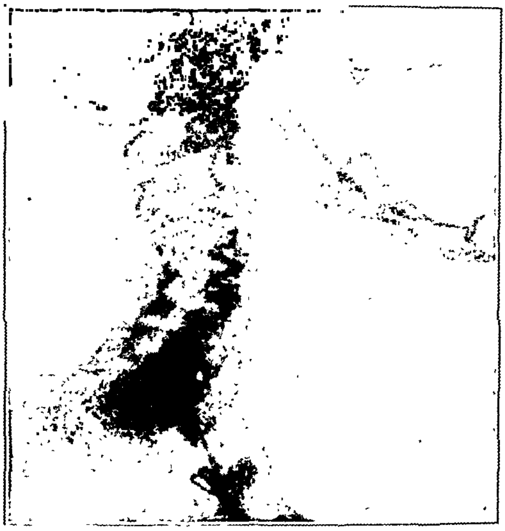

Fig. 2.—Oblique roentgenogram of cervical portion of spine. Note arthritic spurs projecting into the intervertebral foramina.

There are numerous references to the diagnosis and surgical treatment of protrusions of intervertebral disks in the area of the cervical portion of the spine. In my opinion, cervicobrachial pain is not so often due to protrusion of cervical disks as the reader might assume from perusing the literature. From 1938 to 1946 this diagnosis was proved in 15 patients by members of the neurosurgical service, and this group comprised only 2 per cent of the total number of patients with protrusions of disks found at operation.

Of the cases in which roentgenograms of the cervicodorsal part of the spine were normal, the cases which have received the most attention in literature were classified under the general heading of the scalenus anticus syndrome. From 1935 to 1945, 38 patients have been subjected to surgical treatment; i. e., division of the anterior scalenus muscle, by the general surgical, neurosurgical and orthopedic services. No patient with symptoms corresponding to the generally accepted diagnostic findings of this group has been surgically treated on the latter service in the last two years because my associates and I have become increasingly convinced that the basic cause for symptoms appeared to be

variations from the normal in relationship of the shoulder girdle to the thoracic cage, and relief is obtained by correction of the postural defects.

It is interesting to note that in none of the patients personally operated on was there clearcut histologic evidence to prove the presence of a hyperplastic or unusually fibrotic anterior scalenus muscle. It is difficult to conceive of a type of stimulus that would cause this muscle alone to be hyperplastic to the exclusion of all other adjacent muscles.

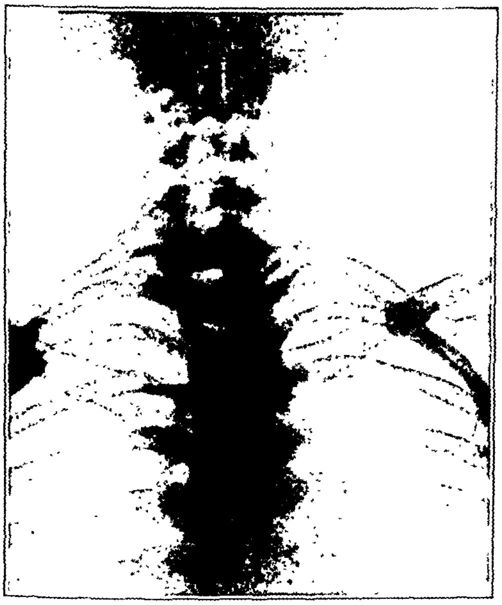

Fig. 3.—Anterior-posterior roentgenogram of cervical portion of spine showing a large cervical rib which articulates with first rib.

Beneficial effects have followed operation in carefully selected cases owing to the fact that one jaw of a vise compressing the neurovascular structures running to the extremity has been removed in precisely the same way that a resection of a portion of an abnormal first rib has relieved individuals in whom cervicobrachial pain was the result of costoclavicular compression, as described by Falconer and Weddell.[9]

I wish to emphasize, however, that in the presence of cervical ribs over 5 cm. in length (Adson and Coffey[4]), and especially those which articulate with the first rib (fig. 3), resection of the anomalous rib is indicated in addition to division of the scalenus muscles.

In 3 cases the basis for the cervicobrachial pain was the hyperabduction syndrome, as described by Wright.[8] It is to be remembered that, as this author indicated, occlusion of the subclavian artery and pressure on the plexus by hyperabduction of the arm is a normal phenomenon on the basis of studies on 150 young adults who, without symptoms, were put through this test. Hence, the anatomic arrangement (fig. 4) that would lead to the presence of this syndrome is present in a high percentage of persons, an important observation inasmuch as the position of hyperabduction is widely but erroneously used as the test for the scalenus anticus syndrome. As reported by Ochsner, Gage and DeBakey,[7] the scalenus muscles are actually relaxed rather than tense in the position of abduction, and hence pain is relieved in the presence of the scalenus anticus syndrome.

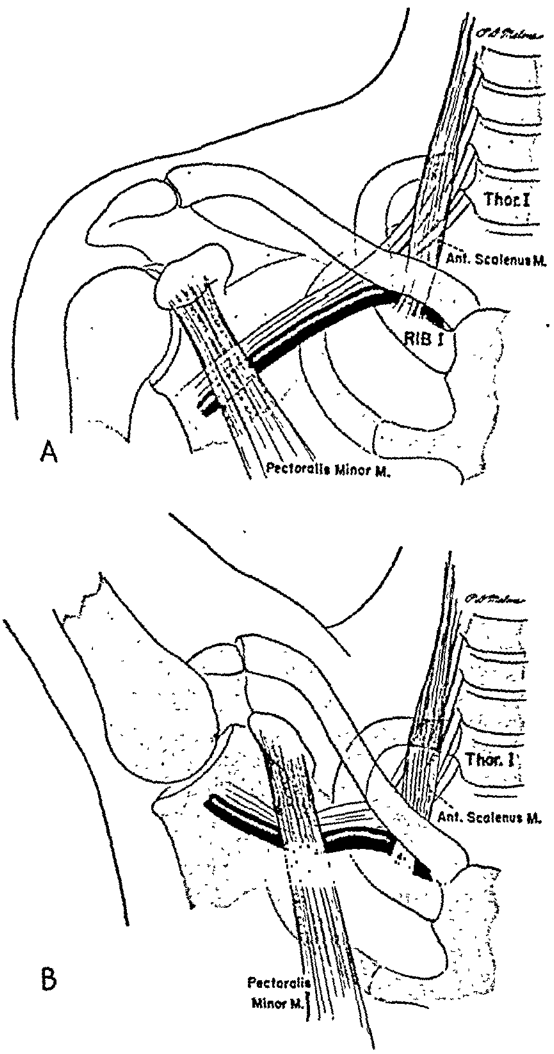

Fig. 4.—The hyperabduction syndrome. Symptoms result from compression of plexus and the subclavian vessels by the pectoralis minor mucle when arm is widely abducted. *A*, arm at side of body. *B*, arm widely abducted. (Redrawn from photographs by Wright.[8])

TREATMENT

The majority of the patients were managed on an ambulatory basis, reporting to the office for instruction in the details of the program of treatment, which is then carried on at home. Thereafter the patient comes in for frequent examinations to observe progress. The exceptions were those persons who exhibited pronounced generalized spasm of the musculature of the neck and shoulders. Confinement to a firm flat bed accompanied by application of moist and dry heat with gentle massage materially expedited relaxation of the muscle spasm. Particularly was this noted in patients with arthritic changes in the cervical portion of the spine. When protrusion of a disk in this area was suspected, as evidenced by radicular distribution of pain in the arm and absence of the usual cervical lordosis in the roentgenograms, intermittent traction to the head relieved pain. In the presence of severe disability and muscle spasm thought to be due to scalenus anticus or the costoclavicular compression syndrome, these patients were also instructed to lie in bed with small pillows under each shoulder, with consequent relaxation of the musculature about the upper portion of the thoracic cage.

Sleeping habits were investigated. In particular, the patient was instructed to sleep with the arms at the side of the body and to avoid abduction of the upper extremity.

In all patients the principal measure for relief of symptoms was a course of graduated active muscle exercises to reeducate and strengthen the elevators of the shoulder girdle, notably the upper fibers of the trapezius and the levator anguli scapulae muscles, as well as instruction to hold the cervical portion of the spine erect with the chin in and to overcome forward position of the shoulders in relation to the thoracic cage. In this connection it is important that the patient hold his head upward and backward, keeping the chin down or in and not simply extending the head backward, which actually may cause increased flexion of the cervical portion of the spine.

In 3 patients with persistent disability and whose roentgenograms did not show abnormalities, gentle traction manipulation with the patient under intravenous "pentothal" anesthesia was performed, with immediate improvement continuing on to complete absence of further cervicobrachial pain.

Eight patients came to us with typical histories of cervicobrachial pain and normal roentgenograms who had been treated elsewhere by the use of a Thomas collar of various materials and types. In our experience these collars are not well tolerated and have not been an aid in overcoming pain.

Many of the women patients, particularly office workers, were found to suffer from a relative vitamin B deficiency, the result of an inadequate diet. Administration of vitamin B complex three times daily, plus dietary instruction, corrected this situation.

Mild analgesics, notably acetylsalicylic acid compound, every three or four hours were of considerable assistance in breaking up the vicious cycle of pain, spasm, more pain and still more spasm, and so enabled patients to progress comparatively rapidly with their exercises.

Finally, the occupational habits that might contribute to faulty posture and muscle stress and strain were reviewed and suggestions were made to correct or omit the type of activity which would tend to produce cervicobrachial pain. Clerks and students who had occasion to spend long hours over a desk with the head and shoulders forward repeatedly noted improvement in symptoms after taking pains consistently to assume an erect posture when at work. This relation of occupation to production of cervicobrachial pain was particularly well demonstrated in a woman of 28, previously a teacher, who had never experienced symptoms until she went to work in a war plant at a task that required her to lift an object weighing about 4 pounds (1.8 Kg.) from below waist level to high above the right shoulder an estimated four hundred times daily. When first seen she was completely disabled, and it was felt that probably surgical treatment would be necessary, inasmuch as the roentgenograms exhibited a cervical rib. Changing her occupation, however, and going on the conservative program as outlined brought dramatic relief in one month's time, and she has remained asymptomatic for eighteen months.

The same program of therapy has likewise produced satisfactory results in those patients coming to us after trauma, such as a fracture of the clavicle or a rib. It is believed that the symptoms were essentially in relation to voluntary splinting and depression of the shoulder due to pain from the injury, causing altered relationship of the shoulder to the thoracic cage that resulted in continuous cervicobrachial pain. Symptoms were relieved when these postural faults were corrected.

It is not my contention that patients with cervicobrachial pain will never require surgical treatment, particularly persons with large cervical ribs. But I do believe that in all the types herein discussed initial conservative treatment is indicated and that in the majority of cases relief of symptoms can be obtained by these nonsurgical methods.

COMMENT ON CASES

Twenty patients with pronounced disability from cervicobrachial pain have been carefully studied. Abnormalities apparent on roentgenograms comprised cervical ribs, 3; cervical disk, 3; degenerative arthritis, 3, and cervicodorsal scoliosis, 1. Patients with normal roentgenograms were 3 with scalenus anticus, 3 with costoclavicular and 3 with hyperabduction syndromes. In 1 patient symptoms developed following trauma. The longest follow-up was seventy-two months; the average, 15.3 months.

The age of this group ranged from 24 to 60 years, the average 39 years. Women predominated over men in the ratio of 3 to 1. Fifty per cent of all patients were employed at tasks which required constant use of the arms or prolonged flexion of neck and shoulders. Thirty-five per cent were housewives, busy with dusting, sweeping, ironing, and so forth. In the remaining 15 per cent, occupation did not appear to be related to symptoms.

The results were classified as excellent, good, fair and poor. A patient was termed as having an excellent result if completely asymptomatic while performing his usual as well as out of the ordinary activities; a patient classified as having a good result experienced some minor discomfort but only when fatigued; a fair result was noted in patients relieved of severe, disabling pain but who continued to experience persistent minor discomfort; no improvement was classified as a poor result. There were 5 excellent results, and it is interesting to note that 2 of these patients had cervical ribs. The other patient with a cervical rib was classified as having a good result. That these patients may eventually come to surgical treatment is an obvious possibility, but they offer a striking demonstration of what can be accomplished by conservative treatment. Of the remaining patients, 11 had good and 3 fair results, distributed as shown in table 2.

TABLE 2.—*Results*

Diagnosis	Excellent	Good	Fair	Poor
Cervical rib	2	1		
Protrusion of cervical disk		2	1	
Degenerative arthritis		2	1	
Scoliosis		1		
Scalenus anticus syndrome	1	2		
Costoclavicular compression	1	1	1	
Hyperabduction syndrome	1	2		
Trauma		1		
	5	12	3	0

The final investigation of a presumptive protrusion of a cervical disk is a myelogram. In the first 2 of the 3 cases, the roentgenographic report was positive, revealing a defect between the sixth and seventh cervical vertebrae. However, the neurosurgical service considered the findings equivocal and in consultation it was decided to try conservative treatment, which has relieved symptoms for twenty-four and eighteen months, respectively. These patients are classified as obtaining a good result but report for periodic check-up examinations. The third patient was clinically similar to the first 2, and because she was so apprehensive, an initial trial of convervative treatment was decided on. After twelve months she is considered to have a fair result.

Patients in occupations which necessitate constant use of the arms and who are often subject to fatigue should be warned against overexercise. This was illustrated in patient 14, a dental hygienist aged 24, with cervicobrachial pain from a scalenus anticus syndrome. In addition to her regular duties she performed the exercises so assiduously that myositis of the neck and shoulder muscles developed, necessitating a short interval of bed rest to control this complication. Thereafter she went on to complete recovery.

Within the past three months 2 patients have been admitted to the orthopedic service because of disabling cervicobrachial pain which was finally proved due to causalgia or sympathetic dystrophy. In neither instance were we successful in relieving symptoms by the conservative regimen described. Complete disappearance of pain followed cervical sympathectomy by the neurosurgical service.

ABSTRACT OF DISCUSSION

Dr. I. W. Nachlas, Baltimore: The increasing recognition of the diseases in and around the neck with associated brachialgia makes it necessary to devote more attention to the treatment of this syndrome. Unfortunately the surgical procedures that were devised failed to solve this problem. It is noteworthy that with conservative methods Dr. Haggart was able to restore 20 consecutive patients with pronounced disability to usefulness, 17 with good and excellent results. He had no failures in this group. This is a heterogeneous group of illnesses that are grouped together only because of the common characteristics, pain in the neck and radiation down the arm. Obviously one pattern of treatment cannot apply to all of the diseases that may affect this area. The aneurysm of the brachial artery or the long irritative cervical rib may require surgical intervention. It is the common denominator, pressure on the brachial plexus, that permits the consideration of one group of therapeutic procedures. Dr. Haggart has presented many theses that have been propounded to explain these pains, but I cannot subscribe to all of them. If one carefully studies the neurologic radiations and tracks them back to an area where one common lesion can produce them one is greatly assisted in arriving at the diagnosis. My belief is that compression within the cervical intervertebral foramina is responsible in many instances. Hyperextension of the involved area opens these foramina, and it is remarkable how often and how promptly this procedure gives relief to the patient. Dr. Haggart's technics are excellent, but a few additional methods implied by him but not specified may be added: The flexion contracture with its muscle spasm must be overcome. Head traction and hyperextension strapping are useful methods. Some men have found injections of procaine hydrochloride in the muscles of value, but the hyperextension so acquired must be maintained by one of the methods available to orthopedists. The important thing to bear in mind is, as Dr. Haggart indicates, that conservative procedures are usually adequate.

Dr. James McAteer, New York: Dr. Haggart's paper is the best that I have read, and I have looked over all the literature. Dr. Nachlas said that most of the cases are due to arthritic changes in the foramina. Other men have said that cervicobrachial pain is due to the fact that the scalenus triangle has been narrowed down. Dr. Brickner, as far back as 1925, advised that some of these patients should have a portion of the first rib removed. Dr. Nachlas also spoke about the hyperextension. That has been helpful in some cases, but Brown and Kuhn brought out that hyperextension caused 3 cases. Hyperextension might bring about cervical brachialgia. In the Navy, it was found that in a large number of these cases the pain came on after a long period in which the men had no exercise. These men were well trained, brought out in excellent condition and good muscle tone, and then went out to the islands and lay around a long time with nothing to do. Suddenly, a ship would come along, and they unloaded it. Immediately, *they complained of pain in the back, shoulders and arms.* These men were helped by being put at rest for a time, and were started back on the road to recovery with physical exercises. I concur with Dr. Haggart that exercise is important. *In my own experience* I have found that gentle club swinging will help. One outstanding case came under my observation, of a violinist, a young lady who practiced for about six or eight hours a day. She wondered why she was getting pain. It was found to be due to her practicing such a long time, so the violin playing was stopped, she was started on physical culture, and put at rest with a pillow between her shoulder blades.A little trick which I use is to take a man's vest and sew a pillow or sandbag about 6 inches wide (15.2 cm.) in the back of the vest. The vest is then put on and fastened, and when the patient lies down, the correct position is maintained, *bringing relief.*

Dr. G.E. Haggart, Boston: Dr. Nachlas wisely advises a search for the neurologic radiation of pain, because in some instances there is a fairly well defined distribution of pain which indicates that the lesion is in a certain area. However, in many patients, and with the aid of neurologic consultations, we have experienced difficulty in clearly demonstrating the site of the etiologic factor. I believe that the various syndromes presented in this paper are real and, while they are not seen every day, if the ones frequently encountered are listed, a diagnosis is thereby more readily determined. I am much in accord with the use of head traction. Time did not permit details but in 3 patients with normal roentgenograms who did not respond to treatment, gentle traction manipulation with the patient under "pentothal" anesthesia resulted in rapid improvement. The remarks of Dr. McAteer bring up one other point; namely, that it is likewise extremely important that patients not overexercise. Dr. McAteer reports on these men in service with loss of muscle tone who experienced symptoms. That certainly does occur. The opposite situation may take place, however, as illustrated by a dental hygienist of 24 in whom severe pain developed. She performed the exercises so vigorously that myositis developed. Bed rest and a gradual resumption of the exercises resulted in relief of symptoms.

TREATMENT OF MULTIPLE MYELOMA WITH "STILBAMIDINE"

Clinical Results and Morphologic Changes

I. SNAPPER, M.D.
New York

Up to the present time 35 patients with multiple myeloma have been subjected to treatment with "stilbamidine" (4.4'—stilbenedicarboxamidine). In this article experiences which have been collected will be reviewed and morphologic changes in the cytoplasm of the myeloma cells which result from this treatment will be discussed.

CLINICAL RESULTS

A. Dosage.—"Stilbamidine" can be given intravenously. If no veins are accessible the drug can also be injected intramuscularly. After a first injection of 50 mg. and a second injection of 100 mg., each subsequent injection should amount to 150 mg. A total of fifteen to twenty injections is usually sufficient to alleviate the pain. "Stilbamidine" should not be autoclaved or filtered before use. The crystal-like substance should be weighed out. For intravenous use it is dissolved in 10 cc. of sterile water; for intramuscular use in 5 cc. of a 2 per cent solution of procaine hydrocholoride. Intramuscular injections should be given with a thin and long needle to prevent the solution from being deposited in the subcutaneous fat.

B. Precautions.—Before treatment is started the renal function should be measured. Phenolsulfonphthalein and concentration tests are necessary and the urea nitrogen and creatinine content of the blood should be determined. During the treatment weekly determinations of the blood urea nitrogen are requisite. These precautions must be taken because in patients with Bence-Jones proteinuria renal insufficiency is a common occurrence. Experience has shown that "stilbamidine" often exerts an unfavorable influence on the function of the kidneys which were previously damaged by protein precipitates in the renal tubules.[1]

In patients who have normal renal function and no Bence-Jones proteinuria the drug can be given daily. When Bence-Jones proteinuria exists and certainly when signs of renal damage are revealed, it is advisable to administer "stilbamidine" only every other day. In some patients with pronounced impairment of renal function the injections were given only twice per week. With care it is nearly always possible to prevent deterioration of renal function during the treatment with "stilbamidine."

C. Diet.—The diet should be poor in animal protein.[2] In test tube experiments the action of "stilbamidine" appears to be neutralized by the presence of nucleic acid. It has been found that arginine also, although in much higher concentration, has a neutralizing effect on the action of "stilbamidine." The neutralizing action of nucleic acid, and to a lesser extent of arginine, may well explain why the maximal effect of treatment with "stilbamidine" is obtained only if the diet is poor in animal protein.

D. Complications.—Aggravation of preexisting renal damage by injections of "stilbamidine" has already been stressed. In the doses mentioned hepatic function is not influenced. The same holds true for the peripheral blood picture; that is, hemoglobin, red blood cells and platelets. In no case in this series has "stilbamidine" led to agranulocytosis or thrombopenia [1]

During the treatment of kala-azar with "stilbamidine," a specific neuropathy consisting of dissociated anesthesia in the distribution of the trigeminal nerve has been frequently observed. This complication sets in one to three months after termination of the treatment with "stilbamidine." The trigeminal neuropathy occurs much more frequently in the treatment of multiple myeloma because the dosage of "stilbamidine" given is much higher than in kala-azar. Usually this neuropathy does not disturb the patients too much. However, in 1 case the facial numbness was accompanied by severe itching of the eyelids which harassed the patient considerably.

E. Results.—In approximately 80 per cent of the 35 patients mentioned, alleviation of pain was obtained. One patient who was treated in February 1945 has become completely asymptomatic and is still doing his daily work as a porter. Improvement of the roentgenologic appearance of the affected bones can be observed occasionally.[3] After the injections of "stilbamidine" are terminated roentgen treatment may be helpful to consolidate the results. Most of the remaining patients suffered relapses of pain within a year after the termination of treatment. Usually the relapses could be remedied, at least partly, by supplementary series of injections. Several patients have died in the course of the two years. As mentioned before, the disease is only temporarily halted. Bence-Jones proteinuria and increase of the serum globulin, if present before the treatment, continue unabated. The results obtained in 12 patients in whom treatment was started more than one year previously are shown in the table. Of these 12 patients 4 died. There are 8 survivors, 5 of whom are ambulant. Their condition may be designated as satisfactory. Five of the 8 survivors have now lived for periods of three to three and one-half years since the first sign of the disease developed; one has survived for six years.

Duration of Disease After Treatment with "Stilbamidine"

Name	Pains Started	Treatment	Bence-Jones Proteins	Abnormal Globulin	Formaldehyde Gel	Result	Condition, April 1948
1. J.G.	Jan. 1944	Feb. 1945	—	2.7	—	Excellent	Living and well.
2. E.W	July 1944	April 1945 June-July 1946 Sept. 1946 Mar. 1947	—	1.6	—	After every treatment pains abated	Condition poor.
3. J.M.		April-May 1946	++	1.9	—	Pains disappeared; died of myeloma of kidney	Died.
4. K.B.	April 1944	April 1946 Sept. 1946 Apr. 1947	++	2.7	—	After every treatment pains abated	Condition good.
5. J.M.		May 1946	++	5.6	++	Pains disappeared; died of thrombopenia	Died.
6. J.B.	Winter 1944	April-May 1946	—	5.3	++	Transverse lesion, cord; pains disappeared; died Dec. 1946	Died.
7. A.E.	July 1944	July 1946 Mar. 1947	—	2.9	—	After every treatment pains disappeared	Condition fair.
8. R.V.	Feb. 1946	July 1946	—	3.4	—	Pains disappeared; relapse April 1947	Condition good.
9. E.R.	Sept. 1945	July-Aug. 1946	—	3.7	+++	Pains disappeared	Condition favorable.
10. G.E.		July 1946	—	3.6	—	Pains disappeared; died of diabetic coma	Died.
11. H.C.	Jan. 1945	July 1946 Mar. 1947	++	7.7	++	After every treatment pains disappeared	Condition fair.
12. S.C.	Oct. 1941	July 1946 Jan. 1947	—	4.1	—to+	After every treatment* pains disappeared	Condition favorable.

*With "pentamidine" (4, 4'—[pentamethylenedioxy] dibenzamidine).

MORPHOLOGIC CHANGES IN THE MYELOMA CELLS

It has been reported that after treatment with "stilbamidine" basophilic inclusions develop in the myeloma cells.[4] It has been found that such changes develop after a total of 1,000 to 1,200 mg. of "stilbamidine" is injected.[5] After termination of the treatment with "stilbamidine" these inclusions persist for many months. The longest period during which these inclusions have been followed after the termination of treatment is eight months.

Histochemical examination has shown that these inclusions contain ribonucleic acid—the specific part of the nucleoprotein present in the cytoplasm of myeloma cells—and "stilbamidine." The presence of ribonucleic acid is indicated by the following three reactions.[6]

1. The inclusions stain deep blue with Wright stain and other Romanowski stains, deep red with pyronine and deep blue with toluidin blue.

2. Ribonuclease is a specific enzyme which depolymerizes ribonucleic acid. After ribonucleic acid has been exposed to ribonuclease, the ribonucleic acid does not take the stains mentioned. In bone marrow smears subjected to the influence of ribonuclease, the inclusions can no longer be visualized by Wright stain, pyronine or toluidin blue.

Lanthanum acetate precipitates ribonucleic acid and thus protects the latter against the action of ribonuclease. After the bone marrow smears have been immersed in lanthanum acetate the inclusion bodies can be stained easily, even after they have been exposed to the action of ribonuclease.

3. The inclusion bodies absorb ultraviolet light of 2,600 angstrom units, which is a characteristic of nucleoproteins.

The results of these three groups of tests indicate that considerable amounts of cytoplasmic nucleoprotein or of ribonucleic acid are present in the inclusions. In addition, these inclusions show two other characteristics, indicating the presence of "stilbamidine."

4. If studied under the fluorescence microscope the inclusions can be recognized by a vivid fluorescence.

5. Inclusion bodies can be demonstrated in photographs of bone marrow smears made with ultraviolet light of 3,300 angstrom units.

As "stilbamidine" is characterized by blue fluorescence and absorption of ultraviolet light of 3,300 angstrom units, the last two results[7] indicate the presence of "stilbamidine" in the inclusions.

It may therefore be considered as probable that the inclusions consist of a conjugation product of cytoplasmic nucleoprotein or ribonucleic acid and "stilbamidine."

A correlation exists between the intensity of the disturbance of the protein metabolism of patients with myeloma and the formation of these specific precipitates in the myeloma cells after "stilbamidine" injections.[5] In almost all patients with increased serum globulin injections of "stilbamidine" cause the formation of these inclusions. In about half the patients with Bence-Jones proteinuria but without increased serum globulin "stilbamidine" causes the formation of these inclusions. In patients without Bence-Jones proteinuria and without hyperglobulinemia the development of inclusions has never been observed up to the present time after injections of "stilbamidine."

COMMENT

Since these inclusion bodies are found only in myeloma cells and in none of the other bone marrow cells whether mature or immature, a special affinity seems to exist between "stilbamidine" and the nucleoproteins of myeloma cells—much more than between "stilbamidine" and the nucleoproteins of other cells. As a matter of fact, there is reason to believe that nucleoproteins of myeloma cells are different from the nucleoproteins of other cells. It is probable that nucleoproteins act as enzymes in the formation of proteins by cells. As myeloma cells manufacture abnormal proteins (Bence-Jones protein, abnormal globulins), it seems reasonable to surmise that the enzymes which form these abnormal proteins—that is, the nucleoproteins of the myeloma cells—are different from the nucleoproteins of other body cells. The fact that in patients with multiple myeloma with a severe disturbance of the protein metabolism the development of these inclusion bodies is more rapid and more intense than in patients with multiple myeloma without changes of the protein metabolism seems to favor this contention.

The demonstration and analysis of these inclusion bodies indicates that "stilbamidine" is fixed in the cytoplasm of myeloma cells in concentrations which are considerably larger than the quantities absorbed by other cells. In this way "stilbamidine" may be used in the future to introduce specific substances or specific energies into the cytoplasm of myeloma cells without damaging other cells.

Actually the action of "stilbamidine" in multiple myeloma may perhaps be compared with the influence of female sex hormone in patients with bone metastasis due to cancer of the prostate or with the action of male hormone in patients with bone metastasis due to mammary cancer. In all these instances pains often disappear, at least temporarily, but the disease progresses nevertheless. Occasionally a favorable result of longer duration is obtained.

SUMMARY

In 80 per cent of the cases of multiple myeloma the pains are at least partly relieved by intravenous or intramuscular injections of "stilbamidine" (4,4′—stilbenedicarboxamidine). The disease is at best halted temporarily; relapses are frequent, and Bence-Jones proteinuria and increase of globulin in the serum are not influenced.

The drug should be handled with care in patients who have impaired renal function, as is frequently the case in Bence-Jones proteinuria.

The drug has no deleterious influence either on hepatic function or on the peripheral blood picture.

In the majority of the cases a dissociated anesthesia of the trigeminal branches sets in several months after the termination of treatment. This anesthesia does not lead to dangerous complications, although occasionally disagreeable subjective complaints of itching of the eyes have occurred.

After treatment with "stilbamidine," a specific alteration of the cytoplasm of the myeloma cells is observed, consisting of the formation of precipitates of ribonucleic acid conjugated with "stilbamidine." It is probable that the nucleoproteins of the cytoplasm of the myeloma cells

[7] Unpublished experiments.

are different from the nucleoproteins of any other cells in the body. "Stilbamidine" evidently has a specific affinity for these abnormal nucleoproteins of the myeloma cells.

CONCLUSIONS

Cervicobrachial pain can result from a variety of causes. The disability is often pronounced. From our experience it is believed that appropriate conservative management of these cases will relieve symptoms—and for an indefinite period—in the majority of patients.

ABSTRACT OF DISCUSSION

Dr. William Dameshek, Boston: It is an honor to discuss Dr. Snapper's paper. The work on multiple myeloma which Dr. Snapper has been doing for the last few years may be said to be brilliant. Together with others he has helped to inaugurate a chemotherapeutic era in the therapy of the proliferative disorders of the white cell-forming tissues. You have already heard about the effects of another chemical, namely, nitrogen mustard, which is of distinct value in Hodgkin's disease. "Stilbamidine" appears to be of at least some value in the treatment of multiple myeloma. Even though the results with this material may not be very good or may be of only temporary value, there can be no question that they represent a definite advance and a promise of things to come. The chief feature which Dr. Snapper has demonstrated is that one can alter the inner metabolism of a given abnormal cell by introducing into it a foreign substance of chemical origin. By this substitution of the relatively innocuous "stilbamidine" for the abnormal protein within the plasma cell some sort of beneficial change may ultimately take place, although the results thus far have not been spectacular. By demonstrating metabolic changes within the plasma cells by the most modern technics of histochemistry, Dr. Snapper has made a truly significant contribution. For a long time hematology was a relatively dead subject, dealing largely with morphology. Then it became physiologic and morphology was minimized. Now with such modern histochemical technics as described by Dr. Snapper, we are entering a new morphologic era in hematology. Dr. Snapper has had a remarkable career in several countries and in his years has investigated many different subjects. Wherever it was carried out, whether in Holland, China or this country, his work has cast light on many obscure phenomena. I am glad to welcome him into the field of hematology, which he has already enriched by his contribution to the physiology of the plasma cell.

DIAGNOSIS OF LESIONS OF THE UPPER PORTION OF THE URINARY TRACT

Fundamental Concepts

IRA H. LOCKWOOD, M.D.,
ARTHUR B. SMITH, M.D. and JOHN W. WALKER, M.D.
Kansas City, Mo.

The importance of the roentgen examination in urologic problems has become increasingly more evident. There are three methods in general use: the plain roentgenogram of the abdomen, retrograde pyelography and excretory urography. Usually two and often all three methods are necessary to establish and correlate the anatomic, physiologic and pathologic findings which confront the roentgenologist in the examination of the urinary tract.

In the plain roentgenogram of the abdomen one must be familiar with the normal anatomic structures; in the urinary tract, the kidneys are the only structures normally visible, and the degree of visibility is dependent on the amount of perirenal fat.

Retrograde pyelography was introduced [1] in 1906 and consisted of visualization of the pelvis and ureter by roentgenograms made after the introduction of contrast mediums into the ureter. In 1910 Uhle and Pfahler [2] first suggested the use of silver iodide. In 1915 Cameron [3] introduced sodium iodide as a contrast medium; the method then became safe and popular. It is now regarded as indispensable in the investigation of many urologic conditions.

Roundtree was able to visualize the urinary tract by means of large doses of sodium iodide injected intravenously. Later von Lichtenberg [4] and Swick [5] discovered a substance which was nontoxic. After this many advances in excretory urography took place. The preparation of the patient is the same as for other methods of examination of the genitourinary tract. A flat roentgenogram of the abdomen should always be made before the injection of the dye, and after the injection roentgenograms should be made at eight, twenty-five and sixty minutes or variations thereof, depending on the condition under consideration and the individual patient.

Visualization of the urinary tract by this method is dependent on the functional activity of the kidneys in excreting a chemical substance in which is incorporated iodine to render the material opaque to the roentgen ray during its passage through the urinary tract. Pritchard [6] expressed the opinion that the amount of dye should be measured in grams of iodine rather than cubic centimeters of dye and that the amount injected should be proportionate to the patient's weight, age and concentrating power. Children up to puberty can handle twice as much iodine per weight proportion as adults, and infants three times as much. The poorer the patient's concentrating power the more iodine he must have to produce satisfactory urograms.

Intravenous urography is relatively harmless. Aside from the inconvenience of missing breakfast, overnight dehydration and possible transitory pain in the arm, the patient is undamaged and may return to work in ninety minutes. However, a word of caution: All of these dyes contain iodine and in a sensitive patient may lead to serious complications. Various types of sensitivity tests have been devised. Our prophylactic measure is to inject less than 1 cc. intravenously and wait for from one to two minutes before injecting the remainder of the dye. One should always have available an ampule of epinephrine in case of an untoward reaction, and in addition oxygen should be at hand in case of pulmonary edema.

The information gained from excretory urography is chiefly physiologic,[7] and the method gives definite and valuable information of the functional activity of the

kidneys. The normal kidney should excrete the dye [8] rather promptly, and this is the purpose of the roentgenogram made at the eight minute interval. The appearance time of the dye in the urinary tract is a good index of renal function. The maximum visualization will usually be obtained between fifteen and twenty-five minutes. Poor visualization means impaired renal function, and the degree of impairment is indicated by the degree of visualization; when poor visualization is obtained the examination should be continued beyond the sixty minute period, as it is often advantageous to take roentgenograms at two and four hour intervals after the injection. Observance of this rule will often save an examination that would be almost valueless if stopped at an earlier interval. Nonvisualization may indicate: (1) pronounced impairment of renal function; (2) temporary inhibition of renal function; (3) permanent loss of renal function; (4) congenital or acquired absence of a kidney.

In the interpretation of the anatomic, physiologic and pathologic findings from an examination of the upper portion of the urinary tract we have divided the lesions into: (1) congenital anomalies, (2) inflammatory involvement and (3) neoplastic lesions.

CONGENITAL ANOMALIES

Congenital abnormalities of the urinary tract are legion, and our knowledge concerning them has been greatly increased by excretory urography. The most common ones are: (1) congenital malposition [9] (ectopic kidney), (2) horseshoe kidney,[10] (3) duplications of pelves and ureters, (4) solitary pelvic kidney, (5) congenital dilatation of the pelvis and ureters and (6) congenital cystic disease of the kidney.

Lowsley [11] has discussed the correction of some of nature's mistakes by operative intervention. In horseshoe kidneys the ureters usually enter the renal pelvis higher than in nonfused organs. Anomalous blood vessels are almost always present. Normal rotation of the kidneys on their vertical axes is prevented by fusion, and hydronephrosis in these kidneys is probably the direct result of interference with normal drainage. The genesis and relation [12] of anomalies of the kidney [13] can be explained on the basis of embryology.

Congenital [14] cystic disease of the kidney is a condition of considerable interest and clinical importance. Clinically it may present itself in a variety of ways. Evidence of infection of the urinary tract is probably the most common and hematuria may be the initial symptom. Not infrequently the finding of bilateral enlargement of the kidney may be the first indication. The exact origin of this disease is not definitely understood, but it is believed to be due to an imperfect union of the tubules of the kidney with the pelvis. It is frequently accompanied by congenital lesions in various parts of the body. In the roentgen examination there is an enlargement of the kidneys, and the condition is bilateral. The diagnosis is dependent on the visualization of the urinary tract. The pelvis is usually enlarged, stretched and elongated, and the pelves and calices may show evidence of pressure defects from the multiple cysts in the kidney. These defects are characteristic in shape, conforming to the rounded contour of the cyst.

Congenital solitary pelvic kidney is a rare renal anomaly.[15] Some interesting theories have been proposed to explain the etiological factors in renal ectopia and agenesis. Most authors report that common occurrence of genital anomalies which prove a close relation of in the development of müllerian and wolffian ducts. This demonstrates the importance of complete pyelographic information in all cases of genital malformation.

INFLAMMATORY INVOLVEMENT

Inflammatory changes in the upper portion of the urinary tract are usually the result of bacterial infection. While many organisms are capable of producing such infection, none produce roentgen changes that are characteristic with the exception of the tubercle bacillus. A lesion of the kidney which may or may not involve the pelvis is a perinephritic abscess. Prehn[16] called attention to rotation of a calix as a pyelographic sign in the diagnosis of perinephritic abscess. Fever is probably the most common symptom. Pain comes next and is usually localized to the loin. The following roentgen signs are definitely helpful: (1) obliteration of the lateral border of the psoas muscle; (2) obliteration of the kidney shadow; (3) curvature of the spine with convexity, away from the abscess; (4) displacement of the colon; (5) displacement, fixation and limitation of the diaphragm; (6) renal fixation; (7) anterior and outward displacement of the kidney, and (8) rotation of the calix in the upper pole of the pyelogram.

Tuberculosis [17] is the only infection of the urinary tract that produces changes sufficiently characteristic to enable one to recognize the etiologic factor involved. On the plain roentgenogram irregular areas of calcification [18] are suggestive of renal tuberculosis. The early changes are best demonstrated by retrograde pyelography. As the disease progresses the entire pelvis becomes involved. Infection shows a predilection for the renal papillae and in these areas caseation occurs, followed by necrosis. In the pyelogram these areas fill with the contrast medium and appear as small irregular defects just beyond the calix. These are known as areas of cortical necrosis and are characteristic of tuberculosis.

Renal carbuncle [19] is a localized massive suppuration within the kidney due to bacterial metastasis. The symptoms are those of infection, malaise, chills and sweats. Urinary disturbances are usually absent. The plain roentgenogram of the abdomen gives no information. Excretory urography fails to reveal any abnormality. Retrograde studies [20] may show destruction or distortion of a single calix.

Next to infection, hydronephrosis is the most frequent lesion in the upper portion of the urinary tract and may be due to a simple mechanical obstruction, as aberrant vessels, bands of adhesions or to inflammatory changes as the result of infection. One may see on the flat roentgenogram of the abdomen some enlargement of the renal shadow. Excretory urography usually shows some

impairment of function, and the retrograde reveals varying degrees of dilatation. The earliest change found on the roentgenogram is a loss of detail in the outline of the minor calices with a slight broadening of the major calices and some fulness of the true pelvis. As the disease progresses there may be a complete loss of the minor calices and a blunting or club-shaped appearance to the major calices.

The size of the renal pelvis[21] is less important than determination of its emptying time. It has been suggested that serial pyelograms be taken at three minute intervals to judge the time necessary for the pelvis to rid itself of injected medium. Frequently, sufficient information can be determined to prove poor drainage from the pelvis by taking a ten minute delayed roentgenogram after the pyelogram has been completed. One must remember that dilatation of the upper portion of the urinary tract is an invariable accompaniment of pregnancy.

NEOPLASTIC LESIONS

Intrarenal lesions may be benign or malignant and are characterized by deformity or distortion of the renal pelvis or calices. The location of the lesion may indicate the type of deformity or distortion which is observed. The changes in the pelvic shadow[22] resulting from either benign or malignant lesions may compress, displace and elongate the pelvis and the adjacent calices. They may encroach on or actually invade the pelvis, destroying its normal outline, producing broadening of the calices, pyelectasis and deformity at the ureteral junction.

Benign tumors often explain an irregularity in outline of the renal shadow and may be the cause of a continued and pronounced hematuria. The diagnosis of angioma[23] of the kidney may be suspected when hematuria and a filling defect in the pyelogram occur in a subject under 40. Absence of a tumor mass or roentgen evidence of renal enlargement tends to support this suspicion. Angiomas may be located in any part of the kidney. Hematuria,[24] in the absence of renal tuberculosis, urinary calculus, infection of the urinary tract and urographic evidence of malignant tumors is suggestive of angioma.

Solitary cysts of the kidney were formerly regarded as rare,[25] but since the advent of urography are found much more frequently. Three groups have been demonstrated urographically: (1) whether the cyst is connected or (2) not connected with the calix or the renal pelvis or (3) lies outside of the renal structure.

The flat roentgenogram of the abdomen, excretory urography and retrograde pyelography constitute the principal means of recognizing cysts[22] of the kidney. They may be single or multiple. If the cyst is small and does not encroach on the calices or the renal pelvis, the pyelogram will be normal, but if it is of sufficient size to bulge into the renal pelvis, a filling defect will be seen. When it involves the lower pole, it may cause hydronephrosis. If the cyst arises from the mesial border of the kidney, the calices may remain normal but the adjacent portion of the pelvis becomes flattened under compressive action of the cyst with changes in position of the axis of the kidney, inward displacement of the ureter and displacement and rotation of the renal pelvis; one may also visualize the cyst shadow or there may be calcification in the cyst wall. The solitary cyst does not produce symptoms except by mechanical pressure, and when this is big enough there will be displacement and compression of the renal pelvis and calices.

Adenomas are frequently associated with cysts. Their incidence increases with each decade past middle life. Adenoma and carcinoma[26] are similar in many respects. They occur at approximately the same age, grow slowly and are found together more often than adenomas are found alone. They are rarely bilateral. The cells deviate from normal renal cells in the direction of malignant characteristics. When the adenoma becomes malignant, a fairly well circumscribed, diffusely infiltrating neoplasm of considerable size may result. The clinical manifestations are: pain, hematuria and tumor. The abnormalities noted in the pyelogram are dependent on the location, size and rate of growth and whether or not the pelvis is involved.

The most common renal tumors in adults are cortical hypernephroid[27] carcinomas. In the young[28] mixed carcinomas, usually called Wilm's tumor predominate. The smaller lesions of hypernephroma have a tendency to be encapsulated. The larger ones show little evidence of encapsulation and may infiltrate into the renal pelvis. One of the striking features of hypernephromas is their tendency to invade the branches of the renal vein.[29]

Carcinoma of the kidney may be considered under two groups: (1) those arising from tubular or glandular epithelium and (2) those arising from the pelvic mucosa. Undoubtedly the most important source of carcinoma in the substance of the kidney in the adult is the adenoma.

Carcinomas arising in the renal pelvis[30] are of two types, papillomatous and epidermoid.

Papillomatous growths of the renal pelvis are similar to papillomas elsewhere[31] and have a tendency to become malignant. The tumor may be limited to a calix or it may fill the entire pelvis. Hematuria is almost a constant clinical finding. Chute[32] reported that in 100 proved cases in 44 per cent of those with hematuria there was cancer of the genitourinary tract, and Kretchmer[33] in 833 cases found that 39 per cent were due to lesions of the kidney.

Tumors arising in the pelvic mucosa but growing into the renal substance rather than into the lumen of the pelvis have the structure of inverted papilloma.[34] Such tumors are referred to as epidermoid carcinoma. They may arise from the pelvis of the kidney, are ulcerative lesions and infiltrate the renal substance, and their usual mode of metastasis is through the lymphatics. Carcinoma of the kidney, like carcinoma elsewhere, has a tendency to invade the surrounding structures and in the pyelogram shows little tendency to displace the calices or the

pelvis of the kidney but does produce irregularity in the pelvic outline with serrated edges indicating invasion. Ackerman[35] described a case of mucinous adenocarcinoma of the pelvis of the kidney in a patient with infection and stones. Hunner[36] stated that cancer of the kidney is often associated with ureteral stricture and that in preliminary diagnostic routine every kidney which is a source of bleeding should be considered cancerous until reasonable proof to the contrary is established.

Sarcoma, in the sense of a malignant tumor arising from the supporting tissue of the kidney, is rarely observed as a primary lesion. It is more probable that a large percentage of cases appearing in the literature under the heading of sarcoma should be classified as embryonal carcinoma or a mixed tumor. Fish and McLaughlin[37] reported a case of lymphosarcoma with the syndrome of recurring abdominal pain, fever and anemia.

Many conditions give rise to tumors in the region of the kidney and on palpation may be mistaken for an enlarged kidney. A palpable mass[38] usually presents a problem in diagnosis. An enlarged spleen, Riedel's lobe of the liver, retroperitoneal cysts, tumors of the descending colon and sigmoid, pancreatic lesions, lymph nodes, mesenteric cysts and tumors arising from the disease of the female adnexa may simulate renal masses. A gastrointestinal examination is a necessity. A shadow on the roentgenogram apart from that of the kidney would be conclusive. Any displacement of the ureter is suggestive of renal tumor, although extrinsic lesions may cause this displacement. An extra renal tumor may deform the pelvis by pressure, while a tumor in the pelvis may not change the contour or outline until it is large enough to produce obstruction.

Shambaugh,[39] reporting on 24 extrarenal masses in the left flank, stated that in 16 instances the left kidney was in a normal position. The extrarenal mass in 1 instance proved to be intraperitoneal, and in the other 15 there was splenomegaly. In 8 cases the left kidney was definitely dislocated; in 6 the mass was due to retroperitoneal tumor, in 3 to malignant lyphomas and in 1 each to neurofibrosarcoma, benign fibroma and a pancreatic cystadenoma. He emphasized that a mass found in the left flank causing displacement of the left kidney will invariably prove to be extraperitoneal.

Many tumors containing ganglionic cells[40] have often been described as arising in the retroperitoneal area. These are as a rule benign tumors, but a few have shown metastasis which seems to have developed from the smaller and less differentiated cells. Lipomatous tumors[41] are characteristic but not frequent growths of the retroperitoneal space. Freifeld[42] has described a lymphoblastoma of the kidney which produced a filling defect in the pyelogram resembling a parenchymal lesion.

CONCLUSION

The ambition of most radiologists is to determine the type of renal tumor with which they are dealing. This of course would be ideal, but a glance at the great mass of controversial literature on the classification of benign and malignant lesions makes it difficult. The importance of a complete roentgen examination has been stressed. The methods used have been discussed and the findings correlated under anatomic, physiologic and pathologic conditions.

ABSTRACT OF DISCUSSION

Dr. H. Dabney Kerr, Iowa City, Iowa: In the short time at the disposal of Dr. Lockwood, it was impossible for him to go deeply into the diagnosis of renal lesions. In the differential diagnosis of renal tumors one must not attempt to make clearcut differential diagnosis between cysts and neoplasms, because many renal cysts will, after they have been removed, show carcinoma on their interiors. In giving intravenous "dye" for intravenous pyelography, it is important to remember that the absence of visualization of the renal pelvis does not necessarily mean impaired function. That was brought out by Dr. Lockwood but probably not with sufficient emphasis. It has been recently demonstrated by Barclay and his associates that there is a lesser circulation in the kidney which acts as a protective mechanism and which may, therefore, in many instances cause lack of visualization of the renal pelvis when there is actually no pathologic condition in the kidney itself. That one must keep in mind. There is a point which I think perhaps is an advantage in the examination of the kidney and one which my associates and I use, not routinely, but in selected cases, and that is the air pyelogram. When one has a nonopaque stone in the renal pelvis or when one is dealing with a small papillary tumor one may cover it up with the opaque medium, but with air pyelography one can demonstrate nonopaque stones and papillary carcinomas or even cellular debris which may have given rise to some bleeding or pain.

INJECTION THERAPY FOR ANGIOMAS

G. MARSHALL CRAWFORD, M.D.
Brookline, Mass.

Angiomas are tumors of endothelial origin and rarely are they malignant. The neoplastic process arises in buds of endothelial tissue which may grow extensively but do not seem to connect with normal vessels in the surrounding tissue. But one afferent and efferent channel is ascribed to the angioma, and occlusion of either should eventuate in regression of the lesion.

TYPES OF LESIONS

Excepting nevus flammeus ("port wine stain"), a large majority of hemangiomas will spontaneously involute at a relatively early age, but therapy is frequently warranted. This applies to both the superficial ("strawberry mark") and deep ("cavernous") hemangiomas, which two varieties are most commonly observed and frequently occur in combination. Nevus flammeus, nevus araneus (stellate or "spider" angioma), senile angiomas, lymphangiomas and more rare forms are not included in this discussion.

INDICATIONS FOR THERAPY

Most strawberry and cavernous angiomas are either present at birth or appear within the first few months of life. Thereafter they may increase in size only in proportion to the growth of the infant, or independent enlargement may progress for a period of some months. Continued growth of angiomas beyond the age of 1 year is unusual but can occur. In view of the pronounced tendency to spontaneous regression of most

---

From the Dermatology Department, Massachusetts General Hospital, Boston.

hemangiomas by the age of 5 to 6 years, some criteria should be established for those deserving treatment. Lesions which interfere with vision, those situated within or about the mouth or in the anogenital region and on pressure areas warrant first consideration. They may impede normal functions or give rise to painful ulceration and perhaps secondary infection of importance. Large angiomas are particularly prone to ulcerate, unless of purely cavernous structure, and regardless of their location. The scars which may then ensue can be disfiguring and of psychologic import in later life. The infrequent lesion which persists all through childhood or into adult life is of the same significance.

It is seldom that hemangiomas give rise to important hemorrhage, interfere with growth or endanger life, except in muscular, visceral or osseous lesions which are not under consideration here.

By far the greatest number of infants are brought for attention by mothers who seek removal of their child's blemish for cosmetic reasons. If none of the aforementioned indications exist and the lesion is not rapidly enlarging, the probability of spontaneous disappearance should be explained. Therapy may still be requested in many instances and is justified if safe and effective.

METHODS OF TREATMENT

Injection therapy for angiomas is not new nor necessarily the best in all cases, but it is simple, efficient, and nonhazardous and has received less emphasis than it deserves. It compares most favorably with other modalities.

Excision is the quickest cure for selected lesions and the results are usually satisfactory. Large angiomas seldom lend themselves to suitable surgical approach, and many small ones are so situated as to make excision unattractive. Surgeons frequently are most reluctant to attack difficult angiomas unless other methods fail. Sclerosing injections and a few months' time, however, often provide a more workable problem for surgical treatment.

Radiation therapy is perhaps the most widely employed method of treating angiomas at the present time. It is effective to a large degree when properly used but carries some hazards and has distinct limitations. Roentgen rays and radium are not generally advised after the age of 2 years. Radium treatments are time consuming and expensive, and require meticulous care. Roentgen therapy is hardly less difficult to administer. Either form of radiation should be avoided on the scalp, around the eyes, lips, genitalia and breasts and over digits, bony prominences or epiphyses; radiation effects on underlying structured must always be considered. It is not generally advisable for extensive lesions anywhere. External radiation, the implantation of radium needles and interstitial radon seed therapy have all been successfully employed but require skill and experience to avoid late radiation sequelae.

Solid carbon dioxide is also used extensively in treating hemangiomas. With sufficient experience, one can develop a technic of application that will briefly freeze a shallow strawberry angioma and speed its involution. It requires skill to accomplish results without the production of scarring. In cavernous angiomas or the mixed strawberry and cavernous types, however, it is extremely difficult if at all possible to achieve any suitable effects without scars.

Surgical diathermy of various types may be employed for special situations, but here again scarring is unavoidable.

PRESENT SERIES

A group of 233 patients with 310 assorted vascular tumors comprised the series under observation. These cases consisted of the following types: Hemangioma 206; nevus flammeus 16; lymphangioma 5, and granuloma pyogenicum 6. Only the 206 patients with hemangiomas will be discussed herein. Table 1 provides the statistical data regarding the ages of the patients and the onset of the 283 lesions presented by these cases.

After age 40	18
Total	283

Multiple angiomas occurred in 55 of the 206 patients (26.7 per cent). The duration of lesions was largely a matter of a few weeks to several months, since the great majority of patients were but infants of a few months' age, or small children. There were 18 cases, however, in which angiomas had been present at birth or from early weeks of life until later years; 1 patient was over 70 years old. These angiomas included 5 persisting from ten to twenty years, 10 remaining to the ages of 21 to 40 and 3 for more than sixty years.

Hemangiomas were known to have occurred in other members of the family in 22 cases. Another of the immediate family group was affected in 15 instances, a more distant relative in 4 cases and 3 patients had both near and far kin with angiomas. A homozygous twin was without lesions in 1 case and a heterozygous twin was unaffected in another instance.

Six patients with angiomas present at birth and persisting for some years had noted growth of their lesions only after periods of three to twenty years. Three women had observed distinct growth of their lesions during pregnancy; 1 noted this phenomenon twice. Trauma was thought to be associated with enlargement in 1 case of this group and also in 4 cases in which angiomas developed later in life.

There was no consistent association of hemangiomas with other tumors or with any given type of disease. Eight patients were afflicted with atopic dermatitis; 2 gave a history of convulsions (not epileptiform); 1 had celiac disease. Five patients had been born prematurely.

The types of hemangiomas encountered in the 206 patients and the locations of their 283 lesions are given in table 2. The strawberry and cavernous lesions were about equal in number, although strawberry elements were also mixed with more than half of the deeper lesions and thus entered into over three fourths of the total. Twenty strawberry marks displayed mature-appearing veins radiating out from the periphery; five were associated with changes of the port wine type.

A word of explanation is due for the senile type of cavernous angiomas. These lesions are not the ruby red, superficial, usually small and frequently multiple angiomas so often observed on the aging integument. They are rather a sharply contrasting type of dark bluish, domed, cavernous tumor more often found about the head than elsewhere. The 18 lesions in this series occurred in 13 patients whose average age at onset was 57 years; the mean duration of their lesions was five years and two months. These eighteen senile cavernous angiomas were found on the face in 6 instances, on the mucous membrane of the lip, tongue or mouth 11 times and once on a thigh.

When the 283 hemangiomas were segregated in accordance with size, their longest diameters were as follows: up to 1 cm., 73 lesions; from 1.1 to 3 cm., 133; from 3.1 to 5 cm., 45; from 5.1 to 10 cm., 19, and over 10 cm., 13. The largest of all was in a clinic patient aged 37 years; this lesion consisted of practically continuous angiomatous changes affecting nearly all of one lateral half of the trunk and the posterolateral aspect of the corresponding thigh. She had first been observed at the age of 5 years, at which time the involved skin was completely covered with a mixed profusion of strawberry and port wine marks plus many underlying cavernous angiomas, all of the abnormalities having been present since birth. When she was called in for examination at the age of 37, all of the cavernous portions had disappeared and many of the strawberry marks were gone; all of the nevus flammeus element remained unaltered according to descriptions in the record and the patient's statement. No therapy had been administered. This case was a perfect example of the so-called neurocutaneous syndrome, but no neurologic aberrations were demonstrable. Two private patients presented the next largest areas of involvement; both were infants under 3 months of age. One lesion included an entire side of the head and neck, extending below the clavicle inferiorly and half obliterating the curve of the neck laterally; the other reached from the base of the neck across the shoulder and throughout the upper extremity to the fingertips, including all aspects. Both had combined cavernous and strawberry elements.

Ulceration had taken place prior to treatment in 27 of the strawberry angiomas and in 22 of the mixed cavernous and strawberry lesions. No purely cavernous hemangiomas broke down at any time. Among the 49 lesions which had ulcerated, 15 involved episodes of hemorrhage; 6 of these were in the mouth or on the lips and 5 were in the anogenital region.

Previous therapy had been administered for 60 of the 283 angiomas reported herein, as delineated in table 3. The results of prior treatment are obviously no indication of the usual efficiency of those methods employed, since the successfully treated patients would not seek further attention. Nevertheless the failures illustrate some of the disadvantages of these modalities. One surgical failure was so classified because of keloid formation. Three lesions treated with roentgen rays and 2 treated with radium revealed irradiation sequelae in the form of atrophic scars with telangiectasia and pigmentation. Seven of the 9 lesions in which carbon dioxide treatment was a failure were *conspicuously* scarred, and the other 2 had been dormant lesions until frozen and then began to grow. All of the lesions treated with coagulation and cautery were notably scarred. In the 2 lesions in which injection had failed inadequate sclerosing therapy had been administered some years earlier and had been abandoned prematurely.

RESULTS OF INJECTION THERAPY

There was no selection whatever of the lesions to be treated by sclerosing solutions. In many instances therapy was requested even after the patient or the mother had been advised that no attention was necessary. A small group was left untreated because of previous measures that were obviously going to become successful or because of accepted advice that therapy was not essential. Table 4 shows the division of the series by treatment cases, observation cases, those lost, and the length of follow-up. No patient was considered adequately observed unless the follow-up period was six months or longer, even though progress seemed satisfactory; those in the latter category were arbitrarily classed as lost along with those who actually disappeared

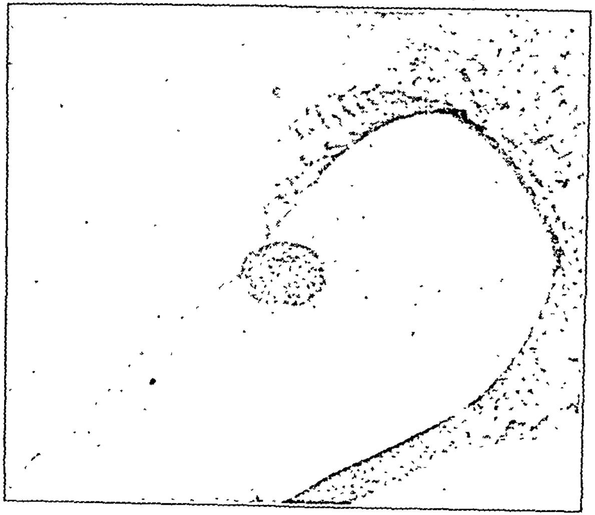

Fig. 1.—T. M. aged 5 months. Showing strawberry hemangioma 1.8 in. in diameter. Eight injections were given in six months.

from observation too soon. The longest period of follow-up was eight years and three months (two patients with two angiomas apiece).

TABLE 4.--*Two Hundred and Six Patients with 283 Hemangiomas*

Sclerosing injections	146	190
No therapy	37	67
Lost to follow-up........	23	26
Total	206	283

Average Time Followed
34.8 mo. per patient
and
35.8 mo. per lesion

In calculating the effects of treatment, an arbitrary estimation of relative success was followed. A good result was defined as 75 per cent reduction in size within one year or complete disappearance of the tumor by the end of observation, and with no more than insignificant scarring. A fair result was 50 per cent decrease in one year, or 75 per cent in two years, or noticeable scars except in strawberry marks over 5 cm. in size. Poor results were 25 per cent resolution in one year, or not over 50 per cent during the time followed, or scars in small lesions. Any lesion less responsive was a failure. Changes in color were largely ignored in estimating the effectiveness of sclerosing injections. The rate of fading was so irregular as to preclude reasonable categories of results of therapy. In many instances the color remained for considerable periods of time after lesions were otherwise obliterated; a halo of irregular blotches was not infrequently visible for many months at the periphery of an otherwise completely resolved strawberry mark.

TABLE 5.—*Effectiveness of Sclerosing Injections in* 190 *Hemangiomas* (164 *Patients*)

	Total............190				Total............190			

A satisfactory outcome was obtained in 90 per cent of the lesions treated by injection; 64 per cent were classed as good and 26 per cent as a fair effect. A poor issue ensued in 6 per cent; only 4 per cent were failures. The results of injection therapy in the 190 treated angiomas were determined from various aspects. Its effectiveness according to the age of the patient, the duration of the lesion, and the location, size and type of hemangioma are portrayed in tables 5, 6 and 7. It is at once evident from these tables that the results are more satisfactory when treatment is instituted in the first few months of life. The same is also seen to be true when therapy is utilized in lesions of short duration, regardless of the patient's age. It is apparent that the size of a hemangioma is of some prognostic import, since the larger lesions were progressively poorer in response. In regard to types of tumors, mixed strawberry and cavernous lesions gave the least satisfactory results and all varieties of cavernous angiomas fared worse than the simple strawberry marks. The location of the tumor appeared to have the greatest significance, since the largest number of poor results and all of the failures occurred on the face or in the mouth. An unsatisfactory outcome occurred in 16 per cent of face lesions and 26 per cent of those in the mouth.

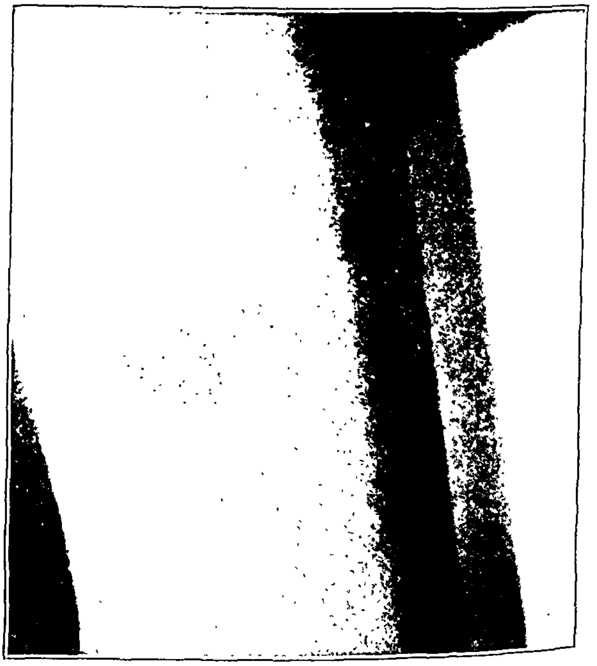

Fig. 2.—T. M., two years after treatment.

The 8 instances of failure were all cases with a background of mitigating circumstances. One patient was aged 2½ years, one was 6 years old and the rest were between 21 and 71 years of age. Six lesions had been present at birth; 1 appeared at the age of 3 months and one at 48 years of age. The last had been present for five years when observed; the duration of the other seven corresponded approximately to the ages of the patients. The locations, sizes and types of these angiomas are shown in the tables. Five patients had previously failed to benefit from other therapy, including cautery, roentgen ray, radium and surgery (2 cases). In another, roentgen rays failed after unsuccessful use of sclerosing injections. One lesion was complicated by a keloid from earlier surgical procedures. Two women had small dormant angiomas until the advent of pregnancy.

The amount of injection therapy required for effective results and the length of time involved could be analyzed from various points of view. The average number of treatments per lesion for all angiomas, regardless of result, was 8.24 injections. This therapy required an average time of 8.34 months. The greatest number of injections given any one lesion was 39; the same case involved the longest elapsed time, or sixty-six months. The patient was a woman aged 39 with a cavernous hemangioma of the lower two thirds of one side of the face since birth; the result was good. The maximum amount of sclerosing solution injected into any patient at one treatment was 10 cc. Table 8 illustrates the time factor in accordance with the duration and type of lesions. This clearly demonstrates the quicker response of angiomas which were of less than a year in duration. It is known that a spontaneous resolution occurs in many hemangiomas within a relatively short period of years. One might thus assume that waiting for five years would bring about a quicker response when therapy was instituted. On the contrary, table 8 indicates that angiomas involute less rapidly when treated after the duration has passed one year, and progressively slower with increased age of lesions.

It is also demonstrated that the senile cavernous angiomas sclerose far more quickly with injections than any other variety of angioma. None had been previously treated. Results with sclerosing injections were predominantly satisfactory despite the fact that all of the senile lesions so treated were situated on the face or in the mouth, where the poorest average results obtained. This circumstance is most fortunate, since senile cavernous angiomas are not appreciably responsive to radiation and are often ill suited to other means of treatment.

When results of therapy with sclerosing solutions were analyzed in accordance with the number of treatments given, by duration and type of lesion, the findings were in close agreement with table 8. This might be expected, since the average number of injections and average months of therapy were essentially the same. The amount of treatment necessary for angiomas on assorted sites and for large or small lesions did not seem to vary significantly. Thus while location and size were of prognostic import, the duration of the tumor and its type were of more influence in regard to quantity of sclerosing injections required. The end results were not in evidence at the termination of therapy in most instances. (Indications for stopping injections are given later in this paper.) The 190 treated lesions achieved their maximum results after therapy as follows: 34 within three months; 76 in six months; 46 at twelve months; 24 at 24 months, and 10 later than twenty four months. Only the type of lesion seemed of significance in this respect. Senile cavernous angiomas were notably the quickest to respond. Strawberry marks, while requiring less average time(and quantity) of therapy than mixed or purely cavernous angiomas, were not appreciably faster in attaining satisfactory effects.

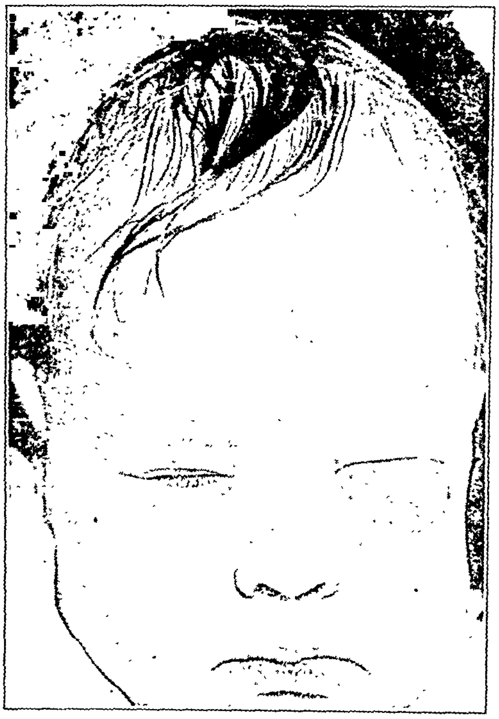

Fig. 3. P.G., aged 3 months. Showing cavernous agnioma 2.5 cm. in diameter. Fourteen injections were given in twelve months.

This paper is concerned primarily with hemangiomas, but it may be said in passing that lymphangiomas have not responded well to sclerosing injections. Five of the 6 patients observed received injections, but their lymphangiomas did not sclerose satisfactorily.

The 6 instances of granuloma pyogenicum, however, did exceedingly well. Four patients were most promptly relieved of their lesion after one injection.

SOLUTIONS EMPLOYED

A solution of quinine and urethane was perhaps in most wide usage just prior to the period of time encompassed by the group of cases reported herein, but none of them were treated with it. This agent was not utilized because a number of patients had been observed whose varicose veins were sclerosed with quinine and urethane, and in whom a sensitization dermatitis developed. Sodium morrhuate (5 per cent) was employed at the beginning of this series but soon abandoned because of reactions. Other sclerosing solutions subsequently utilized and their effectiveness are outlined in table 9. When these results were calculated in percentages there was too little difference among the three agents employed to be of notable significance.

Table 9.—*Results According to Agent Used in Sclerosing Injections* (190 *Hemangiomas*)

Solutions	Results Good	 Fair	 Poor	 Failed
Sodium morrhuate	8	3	1	—
Sodium citrate	32	9	3	2
Monoethanolamine oleate	57	24	4	4
Invert sugar and sodium chloride	25	13	3	2
Subtotals	122	49	11	8
Total				190

A 30 per cent solution of sodium citrate with 1 per cent procaine hydrochloride was next to succeed the morrhuate. Within a few months a distressing reaction occurred and the local anesthetic ingredient was eliminated at once; thereafter, the citrate alone gave no difficulty.

Monoethanolamine oleate was subsequently used in a search for more effective action. Thus substance was made up in 5 per cent dilution, with 2 per cent benzyl alcohol. It seemed to create no less painful local reactions but appeared to provide better results. The largest number of angiomas was treated with this solution, but table 9 reveals no appreciably improved efficiency. Invert sugar was used later. As prepared by our hospital apothecary, the invert sugar solution is of 30 per cent strength, with the addition of 10 per cent sodium chloride and 1 per cent phenylethyl alcohol. It has been comparatively free of reactions, perhaps less painful and productive of essentially as good results as the others.

Although the impression had arisen that sodium citrate was relatively slow and less efficient, table 9 does not bear this out. Nevertheless, citrate solution has been almost entirely superseded in the last few years. Monoethanolamine oleate and invert sugar have been employed in alternate cases without selection, after the latter solution more recently came into use.

Not all of the unsatisfactory results should be attributed to the various solutions, since faulty technic can give rise to more scarring than would otherwise ensue. There were 7 lesions that ulcerated after sclerosing injections were instituted. Five tumors continued to enlarge somewhat during therapy; 3 stopped after a few treatments, but 2 required adjunct measures. One was a gingival lesion which had appeared with the eruption of a deciduous tooth six years earlier. It did not respond to roentgen therapy but was apparently relieved one year later by extraction of the tooth and excision of the lesion. With the appearance of the permanent tooth the tumor recurred, one year prior to observation, and hemorrhages were frequent. Growth stopped after several injections of sclerosing solution and the angioma had receded 50 per cent in six months time. Hemorrhages still occurred at night but less frequently; an oral surgical consultant advised radiation therapy, and the patient was entirely lost from the series. A large lesion covering half the face and neck also received roentgen treatment. This was flat until the age of 6 weeks and then began to swell with increased discoloration. Injections were started one week later. Growth continued slowly for six weeks and the mass then began to expand rapidly, doubling its area and tripling its elevation within ten days. At that point three roentgen treatments were administered at monthly intervals. Growth ceased after three months, but no shrinkage took place after six months and injections were resumed. Altogether twenty treatments were given during a total period of two years. The outcome was remarkably good, with normal contours and but few splotches of color, when last observed at the age of 4½ years.

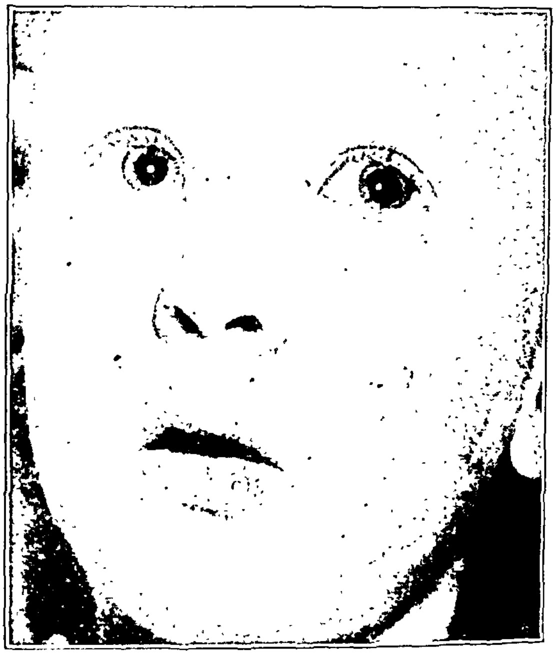

Fig. 4.—P. G., ten months after treatment. One year later this lesion was not detectable.

REACTIONS

Subjectively there is pain of considerable degree immediately on instillation of these sclerosing solutions into the tissues. Patients of sufficient age to offer reliable data have reported sharp pain for five minutes to one hour; dull aching or minor discomfort may persist as long as two to four hours. In about half the cases, however, no appreciable annoyance continues beyond one-half hour unless a large quantity of solution has been injected.

Objectively, the first local change is blanching if sufficient fluid is inserted to distend the tumor or if the injection is too superficially placed. The usual color returns quickly after termination of the treatment, and swelling soon begins. Some angiomas will double their size within fifteen minutes and may quadruple their mass by the next day, with some inflammatory reaction extending to adjacent tissues. This is seldom at all distressing or uncomfortable unless from pressure on underlying structures. It may require a week or more to subside entirely.

Untoward reactions occurred eight times among the 1,566 injections administered in this series of 190 angiomas. In several instances an undesirable episode was credited as a reaction when considerable doubt existed, but among infants and small children any symptom warrants suspicion. The most common systemic reaction consisted of malaise and anorexia with or without vomiting or fever. This happened six times; three of the reactions followed injection of monoethanolamine oleate (one reaction also included a transient toxic erythema); two occurred with sodium morrhuate and one came after injection of invert sugar solution. One patient is included twice, having reacted to morrhuate, and subsequently to monoethanolamine. The latter drug appeared to cause urticaria once. A reaction of the nitritoid type with syncope developed almost immediately after injection of sodium citrate with procaine on one occasion; the baby subsequently received invert sugar solution on several occasions without mishap.

TECHNIC

There is no particular skill required to administer sclerosing solutions by injection. The site of puncture may be either directly into the lesion or through the skin just beyond its periphery. A small caliber needle should be employed (24 to 26 gage) and of sufficient length in accordance with the size of the lesion to require the minimum number of punctures. Hemorrhage has never been a problem regardless of the site of injection; firm pressure is applied for two or three minutes and bleeding is negligible. The number of sites of injection depends entirely on the size and shape of the individual lesion. The quantity of solution instilled at the first treatment varies from 0.05 to 0.5 cc., this again in accordance with the size of the lesion. The first injection may have no effect if the angioma is of appreciable size, but a small dose should cause less systemic disturbance if the patient happened to react. One other qualifying factor enters into the amount of the initial dose. If there is an allergic family background, the first treatment may well be half the customary amount. The increase in quantity of solution can be rapid with additional treatments if the lesion is large. The maximum amount employed in any one lesion in this series was 1 cc. simultaneously into each of ten sites covering a large area. The frequency of injections depends mainly on the relative activity of the individual tumor. If an angioma is steadily enlarging, it may require treatments every week or two until growth is arrested. As time passes sclerosing injections may be given at intervals of one to three months. It is of primary importance to keep the solution from being deposited too superficially, since this will nearly always eventuate in sloughing. If blanching is observed, that particular area has received sufficient fluid and the needle should be moved to another region of the tumor.

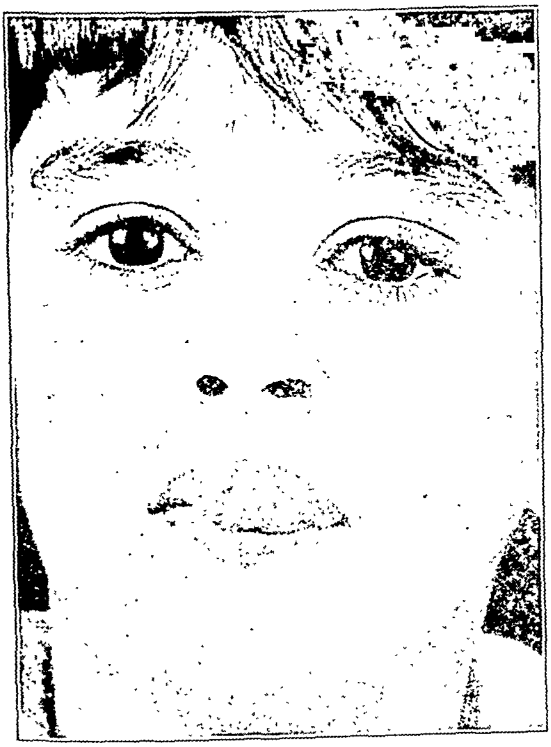

Fig. 5.—F. O., aged 8 years. Neurocutaneous syndrome, with small areas of port wine stain over the entire left side of face and some in scalp, and strawberry hemangioma on lateral half of left upper eyelid. Three fourths of the upper lip showed cavernous angioma. All of the left buccal mucous membrane revealed mixed strawberry and cavernous changes. All of the left side of the face would swell when the head was held down. At the age of 5½ years the left external carotid artery had been ligated and a plastic repair of the lip defect performed; improvement was slight. In ten months the lip received six injections and the eyelid and buccal mucous membrane five each.

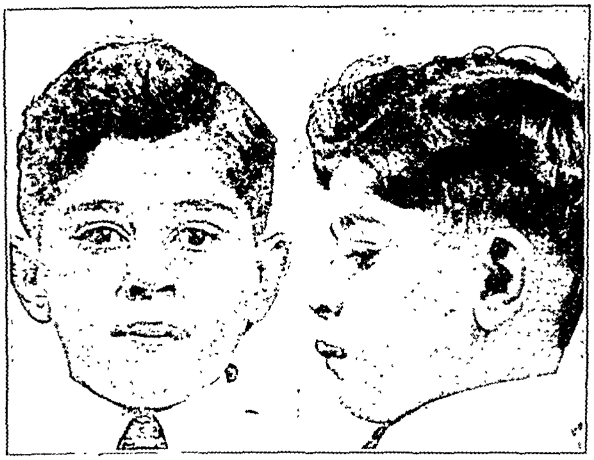

Fig. 6.—F. O., eighteen months after treatment. The cavernous lesion on the lip is strikingly improved and the strawberry mark on the eyelid is definitely regressing. There is little change visible in the port wine elements. Involvement of mucous membrane has decreased about 75 per cent.

In treating the mixed variety of hemangioma, attention need be directed only to the cavernous portion; by the time this element has received sufficient therapy, the strawberry features of the lesion will nearly always have made decided progress toward obliteration, and they may require no additional injections. If a patient returns with local reaction from a preceding treatment still in evidence, or if the lesion shows no residual reaction but is firm throughout, additional injection should be postponed. If a large cavernous angioma seems unduly slow in response to sclerosing injections, the first encouraging sign may be cordlike thickening which can be palpated within its depth. Frequently in the earlier period of this work a patient was advised that surgical procedures or some other adjunct measure would probably be necessary. When they demurred and returned after periods of three to six months, many of the lesions showed surprising improvement. Thus it gradually became evident that haste is not necessary once the growth of a lesion has been arrested. When a lesion can be reached from either a cutaneous or mucous membrane surface, experience indicates that there is less discomfort from the injections when administered through the mucous membrane; this applies to eyelid lesions as well as oral tumors. No local anesthetic was employed prior to any injection.

UNTREATED GROUP

The 37 patients who were not given sclerosing injections exhibited 67 lesions. Their angiomas consisted of 46 strawberry marks, 8 purely cavernous structures, 8 of mixed type and 5 senile cavernous lesions. These cases were followed for periods of one to five years, with an average observation period of 23.2 months per lesion.

Among the 46 strawberry angiomas, 9 had been previously treated, needing no additional attention. Eleven involuted spontaneously, 11 were gradually regressing, 12 remained unchanged and 3 grew steadily larger.

The 8 cavernous hemangiomas eventuated as follows: in 3 tumors results of previous treatments were good; 3 regressed steadily, and 2 remained unchanged

Mixed strawberry and cavernous tumors, numbering 8, slowly improved in 3 instances, were stationary in 2 and enlarged in 3.

All of the 5 untreated senile cavernous angiomas were apparently fully matured and exhibited no further change. One had existed for twelve years before observation and was followed three more years, remaining fixed.

COMMENT

Injection therapy for angiomas is far from being a new approach. This method was used nearly one hundred years ago to produce sclerosis in aneurysms and varicose veins.[1] A great variety of substances have been injected from time to time throughout succeeding years. Some of these include ferric salts, mercuric chloride, red mercuric iodide, antipyrine, sodium salicylate, arsphenamine, iodine, potassium iodide, iodotannic acid, acetic acid, citric acid, alum, phenol, chloral hydrate, silver nitrate, sodium chloride, dextrose, quinine salts, urethane, urea, alcohol, sodium morrhuate, sodium citrate, monoethanolamine oleate, invert sugar and boiling water. Most of these agents were quickly abandoned, some of them because of serious consequence. With the passage of time and the use of safer solutions, there is practically no hazard remaining. There is one series of 325,000 cases of varicose veins cited [1] without pulmonary embolism.

Andrews,[2] Kaessler [3] and Watson and McCarthy [4] have reported satisfactory results from the use of sclerosing injections for hemangiomas in groups of patients large enough to warrant proper conclusions. Andrews' series includes 408 cases in which he achieved 70 per cent perfect results and 10 per cent additional satisfactory response. He compared this group with 146 cases in which treatment was by means of radium. The latter method provided 65 per cent perfect results, and 23 per cent were satisfactory. It was Andrews' feeling that injection therapy was more desirable in many regions where radiation is hazardous. He felt that the duration of treatment was appreciably shortened by the use of sclerosing solutions. Andrews stated that injections should be employed more extensively because of their "effectiveness, freedom from danger, and simplicity."

Watson and McCarthy [4] described the results of treatment in over 1,300 angiomas by several methods. They found that excision provided the highest percentage of good results, but that particular group of patients was most carefully selected and they warned against a keloidal tendency. In spite of the selection of cases for surgical treatment, these authors found it possible to obtain nearly as good results with either solid carbon dioxide or sclerosing solutions. External radium, interstitial radium and roentgen therapy were successively less satisfactory in their series.

There is differing opinion regarding the advisability of irradiation in the majority of hemangiomas. At the Massachusetts General Hospital the feeling of our radiologists is: "Usually radiation therapy of any sort is contraindicated in hemangiomas. The cavernous type is difficult to control because of the size of the vessels and the maturity of the cells; strawberry angiomas respond readily to radiation but the majority of these will disappear without treatment. Rarely in large tumors that have a tendency to bleed easily, where one's hand is forced by a rapidly growing tumor, or where the persistence of the tumor will cause deformity of a growing part or may be a hazard to life, small doses of roentgen therapy may be given, but we prefer to use some other method of control, such as injection, which does not harm the overlying skin. It does not seem justifiable to compromise the skin over a benign lesion, which is probably going to disappear anyway, and so run the risk of undesirable late sequelae." [5] Pfahler [6] disagreed and has reported a large series of cases treated by radium with satisfactory results. The time required for therapy was a year or longer per lesion. Pfahler stated that "hemangiomas rarely if ever regress spontaneously." In contrast, Anderson [7] expressed the opinion that all angiomas should be left strictly alone until the patient is at least 6 years of age, believing that spontaneous involution will have occurred in the majority by that time. The best control series found in the literature was reported by Lister,[8] who followed a group of 77 children with 93 untreated vascular nevi for a period of one to seven years. All except one lesion disappeared or were well on their way by the age of 5 years. It was interesting to review a report by Traub [9] published about fifteen years ago. He gave therein the results of a questionnaire answered by ninety members of the American Dermatological Association. The consensus regarding behavior of angiomas and the advisability of treatment was in agreement with the findings among the cases reported herein.

A few additional observations regarding injection therapy for angiomas will bear comment. It is a most favorable indication for all of the color to disappear from a lesion under diascopic examination; the contrary is true if an appreciable amount of pigmentation is found under diascopy. Lesions which display patches or even small flecks of paler color have already begun some degree of spontaneous sclerosis and will probably progress nicely under treatment; the darker the color, the more likely that the response will be slow. The more superficial or shallow angiomas are apt to be the most tardy in returning to normal color. Those angiomas exhibiting visible sprays of radiating vascular channels which appear to be mature vessels are often exceedingly slow, and the individual vessels may remain unaffected by sclerosing injections. Electrolysis is most suitable for the obliteration of these structures. Whether a vascular tumor will swell in one position or another, or with any form of physical exertion, seems to have little prognostic significance. On the other hand, the slower the rate of refilling after the blood is forced out of an angioma, the more favorable is the prognosis. It will bear emphasis again that mothers should be advised regarding the likelihood of spontaneous involution and that they should also be warned, in the case of large lesions, that the lesions may ulcerate whether or not treatment is instituted.

SUMMARY

The common types of vascular nevi have been described and their probable mode of behavior portrayed. The indications for and advisability of treatment have been discussed. The various methods of treatment are outlined. Most of them will be successful when properly administered.

A group of 233 patients with 310 vascular tumors comprise the series under observation. These provided a series of 190 hemangiomas which were treated by the injection of sclerosing agents. The technic of injection therapy is simple and the procedure is not hazardous. Good results were obtained in 64 per cent of the entire group, and an additional 26 per cent had fairly good effect. Only the remaining 10 per cent of the lesions came out poorly or were failures.

These results compare well with published statistics but are less favorable than some. It seems doubtful whether any better cosmetic effects can be obtained with other methods. Sclerosing injections perhaps bring about little or no more rapid involution of lesions but should provide less scarring. It was obvious that the youngest patients and the lesions of shortest duration responded most satisfactorily. Lesions located about the face and in the mouth gave the poorest results.

It is not the purpose of this paper to indicate that sclerosing injections are remarkably superior to other means of treating angiomas. The method of approach for any given lesion should be selected in accordance with the individual circumstances, and other measures may seem better advised than sclerosing injections. It might be said, however, that this form of treatment more nearly approaches a means of assistance to the natural processes which tend to bring about spontaneous sclerosis in hemangiomas.

ABSTRACT OF DISCUSSION

DR. H. FORD ANDERSON, Washington, D. C.: In the past twenty years as dermatologist to Children's Hospital in Washington, and in private practice, I have had the opportunity to direct treatment in hundreds of cases. Thrombosing solutions of various kinds have been used since 1927, after observation of the work of Planner in Kyle's Clinic and Fuhs in Arzt's Clinic, with both varicose veins and vascular nevi. In handling the problem of therapy in nevi, it is difficult to lay down too fixed a rule as to the efficacy of one method over all others. As time goes on, the signs of self involution are watched for more and more, and when they are found, of course the tumor is watched carefully but no therapy is instituted in by far the large majority of instances. When, for one reason or another, therapy is considered advisable, the choice depends to some extent on the experience and peculiar proficiency of the operator in one or another method of procedure. Some become more proficient in the use of one method of approach and naturally will choose that modality when there is a close decision to be made between modes of attack. In many instances, the same tumor can be equally well disposed of by one or another operator, each using one of four or five of the well recognized methods of approach. We should do all in our power to become adept in choosing and administering the best therapy in the particular case, no matter what method it is, excepting probably extensive, intricate or plastic surgery, when we should see that the best available plastic surgery is employed. In this day and age, this degree of expertness cannot be attained without a comprehensive knowledge of the use of thrombosing agents. It is here that the author is justified in adding his valuable contribution to those of Andrews, Kaessler, Watson and McCarthy and others. In 1938, Andrews emphasized the effectiveness, simplicity and relative safety of the injection treatment, but not to the exclusion of other procedures. In this whole problem, one cannot emphasize too strongly one thing, and that is to proceed slowly and always be reluctant about using any kind of treatment after involution has once begun. This must be stressed most when radium or roentgen rays are employed.

TREATMENT OF ECZEMA (ATOPIC DERMATITIS) IN INFANCY

JEROME GLASER, M.D.
Rochester, N. Y.

Atopic dermatitis, most commonly known as infantile eczema, is the most important skin disease of infancy and childhood. It is not the most common one, since most infants escape this altogether while practically every infant has at one time or another at least a minimum of seborrheic dermatitis in the form of "cradle cap" or of eczematous dermatitis of the contact type, particularly in the form of a diaper rash. The eczematoid dermatoses commonly start on the cheeks, and at the onset it may be difficult or impossible to determine whether one is dealing with atopic, seborrheic or contact dermatitis. It is also possible for the inexperienced or careless person to mistake other diseases such as scabies, psoriasis or pediculosis for atopic dermatitis, but fortunately these conditions are not common in infancy and childhood, and the diagnosis of atopic dermatitis is not often mistakenly made in this age group.

No one pretends that the treatment of atopic dermatitis is completely satisfactory. The problem is to do the best one can with a disease which is usually self limited, with a tendency to spontaneous remissions and eventual recovery regardless of therapy. However there are two reasons why one should not depend too much on nature for the eventual cure of the patient:

1. There is no way of telling in advance which patient will "outgrow" atopic dermatitis and which patient will not. It is a great tragedy, particularly for a girl, to be obliged to pass through puberty into young adulthood with a diseased skin. The psychic trauma in such cases is often far out of proportion to the actual discomfort caused locally by the dermatitis. Every effort should be made to clear the child's skin as soon as possible and to continue to keep it clear.

2. The presence of atopic dermatitis is an indication that one is dealing with an allergic child. This means that only one phase of a cycle which may go on with varying manifestations and with varying degrees of intensity for the rest of the patient's life is being observed. The object of treatment should be not only to relieve the present complaint but to outline a way of life which may possibly prevent the development of other and perhaps worse allergic diseases, such as asthma, in the future.

It is not the purpose of this discussion to consider thoroughly the controversial problem of the prophylaxis of allergic diseases.[1] It can at least be said of the

various measures which have been advocated that they do no harm. It will take years of careful, well controlled study to discover if they really help, and it is my feeling that meantime the patient should be given the benefit of the doubt. A rather concrete bit of evidence of the possible value of one of such procedures is the work of Grulee and Sanford,[2] who in a study of over 20,000 infants at feeding stations in Chicago found the incidence of "eczema" lowest among breast-fed infants, twice as great among those partially breast fed and seven times as great among those completely artificially fed. This work, which is of sufficient importance to be checked by other investigators, should be sufficient indication, if confirmed, of the need of breast feeding for infants born in allergic families. It is too often forgotten that breast milk is the only natural food for the human infant, at least during the first months of life, and that the cow, deserving as she is of the title of foster mother of the human race, after thousands of years of domestication still produces milk primarily designed for calves and not for human beings.

The treatment of any given case of atopic dermatitis resolves itself into the following procedures: (1) prophylactic measures, briefly mentioned before, (2) environmental control, (3) local therapy, (4) systemic therapy and (5) dietary therapy. The sixth procedure, specific treatment, which consists in finding and eliminating the causative allergen when possible, is sometimes involved in the five foregoing procedures, but assistance is often received in this direction from cutaneous testing.

It was formerly believed that in infancy ingested allergens played the most important role. At present there is no certainty of this. It is now generally accepted that atopic dermatitis may at times be caused by direct contact of the skin with allergens (transepidermal penetration[3]) as well as by allergens which have been inhaled and which reach the skin through the blood stream as do the ingested allergens.[4] It is also probable that atopic dermatitis and contact dermatitis have been too sharply separated in the past. This has recently been emphasized by Hill[5] and by Ratner.[6] In connection with this subject, it should also be mentioned that there is doubtless a close relationship between seborrheic and atopic dermatitis. Often an infant will be observed with what appears to be typical seborrheic dermatitis, which as the child grows older gradually develops into typical atopic dermatitis.

The characteristic distribution of atopic dermatitis, with the lesions worse on the face, the area of the arms below the elbows and the area of the legs below the knees, suggests a possible contact origin. It is tempting to consider that such lesions might be caused by a ubiquitous and powerful allergen, house dust, which could act either by contact or by inhalation.

The often remarkably beneficial effects of hospitalization are commonly attributed to avoidance of house dust as well as of other environmental allergens. Some allergists are treating patients with atopic dermatitis by the injection of house dust extract, and although these studies have not yet been published good results are claimed. It impressed me that if house dust does cause atopic dermatitis positive reactions to patch tests should be obtained with house dust extract. Forty-two successive infants and young children with typical atopic dermatitis were given patch tests with concentrated pooled house dust extract. Both aqueous and lipid fractions were used. In this series there were three definitely positive reactions and two questionable reactions to the aqueous extract. Four infants gave definitely positive reactions to the dust lipid, and there was one questionable reaction to this extract. Only 1 patient reacted positively to both the aqueous and the lipid preparation. In this particular case good results were obtained after the injection of dust extract containing both fractions. However since other measures were also used the occurrence in this case proves nothing, and the problem is still being investigated. Stroud[7] has reported cases of dermatitis in adults due to the lipid fraction of house dust.

While positive evidence is lacking that house dust may cause atopic dermatitis, the allergist is justified in advising an environment as free from dust as possible for the patients involved both as a possible therapeutic measure and as a prophylactic one. In addition, specific directions should be given for avoiding other material to which the infants are or may become easily sensitized, such as feathers, wool, animal pets, silk, clothing dyes, soap and others which may be indicated.

One of the major problems in environmental control in the colder parts of the United States lies in providing children with adequate protection by means of clothing which does not contain wool, particularly with regard to snow suits and other articles of winter apparel. This has lately been achieved by using tightly woven cotton cloth of good quality with spun glass fiber[8] as an insulating material between the outer and inner layers. This is said to be superior to wool as regards warmth, and such clothing may prove invaluable in the care of the atopic child. While it is possible to weave blankets of spun glass fiber to take the place of wool blankets, their expense precludes general use. It is hoped that eventually less expensive blankets will be put on the market patterned in construction after the snow suits.[8a]

An important part of the local treatment of the child with atopic dermatitis is the cleansing of the skin by means of bathing. It is a matter of common experience that in most patients with this disease the condition is made worse by the use of soap. According to Sulzberger and Baer,[9] the exact mechanism of this is unknown. They suggest that soap, by virtue of its degreasing and keratolytic action, favors the percutaneous penetration of environmental allergens to which atopic patients are often highly sensitive. To obviate the disadvantages of soap, untreated vegetable oils or mineral oils were used for cleansing the skin. Later sulfonated oils were found to be somewhat superior. All oils, however, have the psychologic disadvantage of not making suds. Most satisfactory to date have been the newer wetting agents derived from lauryl alcohol. These are active detergents and make suds, but they also defat and dry the skin and may act as sensitizers although this rarely occurs in infants and young children. Two particular preparations, "lowila cake"[10] and "dermolate,"[11] are supplied in the form of soap bars. This is particularly useful because it gives the mother the feeling that she is simply using another kind of soap on her baby.

For bathing, colloid baths are commonly used and are highly satisfactory. The simplest is prepared by adding a cup or two of corn starch to a tub of tepid water. The patient is soaked in this for ten or fifteen minutes, and with this the detergent may be used. The patient should be dried by sponging and not by rubbing. Tar baths are also useful. The most readily available preparation is liquor carbonis detergens (liquor picis carbonis N.F.). This is a saponified alcoholic extract of coal tar. Two cupfuls are added to a tub of water and the patient allowed to soak for ten minutes. The "Almay tar bath"[12] is a useful commercial preparation made from juniper tar (oil of cade), and two to four tablespoons are used in a tub of water.

The local treatment of atopic dermatitis depends on whether the condition is acute, acute exudative, subacute or chronic. Probably the best treatment for the exudative stage is the application of 0.5 per cent solution of aluminum acetate in a 1 to 20 dilution.[13] Potassium permanganate in dilutions of 1:5,000 to 1:10,000 may also be used. A saturated solution of boric acid is satisfactory but should not be used long or extensively as it is not without danger.[14] Ratner,[6] pointing out the difficulty of applying wet dressings to the skin of patients at this age, recommended painting the raw or oozing areas with a 2 to 4 per cent aqueous solution of gentian violet medicinal, over which calamine lotion in single or double strength with or without phenol may be applied if desired. In the acute stage, the so-called 1-2-3 ointment may be used. This consists of one part of aluminum acetate solution, two parts wool fat and three parts paste of zinc without salicylic acid.[15]

In the subacute and chronic stages other ointments are employed. The single most effective ingredient is tar. The exact mechanism by which tars exert their clinical effect is not known. Occasionally a tar from one source will be completely ineffective while a tar of other origin will be completely satisfactory in the treatment of the same patient. Because of the disagreeable appearance of crude coal tar and of ointments containing tar, attempts have been made to extract the active antieczematous principle. Nelson and Osterberg[16] extracted the steam distillate of crude coal tar with ether and obtained a product commonly as efficient as crude coal tar but almost white. This preparation is the base of most of the so-called white tars now on the market. Dr. Samuel W. Clausen, of the Department of Pediatrics of the University of Rochester School of Medicine, obtained a highly satisfactory product in 1929 simply by the extraction of crude coal tar with hot alcohol.[17]. Irritating material is removed by low pressure distillation. This extract is commonly used in 3 per cent strength in an ointment base.

One of the most satisfactory vehicles used in atopic dermatitis is paste of zinc without salicylic acid. This product has been included in the National Formulary since 1942 and is made up of one part zinc oxide, one part starch (corn or arrowroot) and two parts white petrolatum. This is an excellent vehicle for tar or tar extract, mercury, sulfur and other drugs. Phenol in proportions of one quarter to 1 per cent is sometimes added as a local anesthetic if the area to be covered is not excessively large. Salicylic acid may be added in proportions of 1 to 3 per cent depending on whether a stimulant or a keratolytic is desired. "Vioform" (5-chloro-7-iodo-8-hydroxyquinoline), introduced into this country by Sulzberger and his co-workers,[18] is occasionally helpful in atopic dermatitis, especially if the skin is superficially infected. It is somewhat more useful in seborrheic dermatitis. It is used in 1 to 3 per cent concentration in petrolatum or in a vanishing cream base.[19] Hill[20] has reported good results in the treatment of chronic stubborn patches of atopic dermatitis with the Swartz ointment (4 per cent merbromin with 6 per cent salicylic acid, sufficient water to dissolve and sufficient wool fat and petrolatum to make 2 oz. [60 Gm.]). Robinson[21] favored the compound resorcin ointment (N.F.). There are also on the market many proprietary ointments whose composition is not completely known, some of which are exceedingly effective. However, as Ratner[6] has pointed out, if one consults the United States Dispensatory he will find listed practically every ointment in common use, and by a proper utilization of this information ointments can be created to fit the needs of the individual patient.

In all instances of atopic dermatitis it is well to put the child on a simple elimination diet. Such a diet for a child of 1 year of age or less may be easily made up from the following ingredients, the number of the ingredients depending on the age of the child: (1) cow's milk substitute, (2) one single pure cereal such as oatmeal, (3) two vegetables (carrots and string beans), (4) two fruits (apple and pear), (5) one meat (capon or rooster) and (6) vitamins A, D and C. Even for children up to the age of 1 year a trial diet consisting only of the cow's milk substitute may be used and the other ingredients added gradually if the skin improves.

The substitution of the milk of another species of mammal is occasionally successful if the patient is sensitive to lactalbumin, which is species specific. However the great majority of infants who are sensitive to milk are allergic to casein, and this is essentially of the same composition regardless of the species of the animal. I therefore commonly use soy bean milk. If an infant is sensitive to soy bean, a satisfactory artificial milk whose protein base is meat[22] may be used with complete satisfaction of the requirements for growth and development. Liquefied meats are now available commercially which may be used for this purpose.[23]

Chicken is used as the meat in the aforementioned diet because in my experience allergy to this occurs less often. Capon or rooster is specified on both theoretic and practical grounds to avoid feeding the infant egg protein as infants are more commonly sensitive to egg than to any other food except perhaps milk. The theoretic consideration is that one of the constituents of egg albumin, conalbumin, corresponds to serum albumin in the blood of the hen[24] and this is present in sufficient quantities to produce symptoms on ingestion of the meat. The practical consideration is that if the hen is used the meat may be contaminated by egg protein when it is cleaned.

Because cod liver oil has on occasion produced allergic reactions in infants,[25] "provatol" (Wyeth, Incorporated) is used. This consists of provitamin A (carotene) together with irradiated ergosterol of vegetable origin dissolved in sesame oil to provide vitamin D. To provide vitamin C, crystalline ascorbic acid may be prescribed or "cecon" (Abbott Laboratories), which consists of 10 per cent ascorbic acid dissolved in propylene glycol.

If, after a period of seven to ten days the child obtains adequate relief on this diet, one new food may be added each week or so according to his needs and tolerance. If the child does not do well, simple variations may be made in the various dietary constituents which are occasionally helpful. However at this point cutaneous testing is sometimes useful in enabling one to select a diet which has the best chance of giving relief as well as being of assistance as a guide to the foods which may be added to the diet in the future. When giving cutaneous tests, one also endeavors to find clues to environmental factors, such as inhalants and contactants, which may contribute to the child's disability. In infants and young children scratch testing is the procedure of choice. If intradermal tests are used, one should be sure that each test has been preceded by a negative reaction to a scratch test in order to avoid generalized reactions which may be serious and which may even on rare occasions result in the death of a highly sensitive child. Direct testing is commonly the most satisfactory procedure although passive transfer tests should be done when the skin is generally involved.

SYSTEMIC MEDICATION

The most disagreeable symptom of atopic dermatitis is itching. Occasionally the so-called antihistamine drugs (diphenhydramine hydrochloride ["benadryl"] or tripelennamine hydrochloride ["pyribenzamine"]) will give gratifying relief, but this usually is inconstant and variable. The sedative action which these drugs sometimes have may also be helpful. However it must be realized that sometimes apparent sedation which follows these drugs is due to the relief of symptoms so that the exhausted child sleeps naturally. Phenobarbital, especially in combination with acetylsalicylic acid sometimes helps. "Demerol" (1-methyl-4-phenyl piperidine 4-carbonic acid) is often most useful. An infant 2 months of age and upwards may be given one quarter of a 50 mg. tablet every four hours and the dose gradually increased, if necessary, until relief is obtained or until one tablet is given every four hours.[26] Because of the danger of addiction, however, routine or prolonged use of the drug is to be avoided.

Hansen and his associates[27] and Stoesser[28] have shown that in atopic dermatitis there is often a deficiency of the unsaturated fatty acids of the blood and that improvement of the skin condition is associated with an increase in these fatty acids. This observation has led to corresponding therapeutic measures, and in some instances the results have been beneficial. There are obvious difficulties to well controlled clinical feeding experiments, but at least this is a procedure which is not apt to do harm and which has a reasonable chance of success. Fortunately soy bean oil is rich in unsaturated fatty acids and may be easily fed to infants and children. Lard also is used. It should be emphasized that the proponents of this method offer it as an adjunct therapeutic measure and not as the sole method of treatment.

Chronic atopic dermatitis will in rare instances respond remarkably well to the oral administration of potassium arsenite solution. With a chronic disease of this character one hesitates to use arsenic. However now that 2,3-dimercaptopropanol (BAL) is available as an effective antidote for arsenic poisoning perhaps the use of arsenic in atopic dermatitis should be more thoroughly investigated.

One of the most common errors in the treatment of children with atopic dermatitis and indeed in the treatment of allergic children generally is failure to give routine prophylactic treatment for diphtheria, pertussis and tetanus for fear of disagreeable reactions on account of the child's allergic constitution. In my experience in the general practice of pediatrics, largely dealing with allergic infants, disagreeable reactions of any significance are no more common in allergic than in nonallergic children. If desired, the injections may be started with a half or a quarter or even less of the orthodox dosage, and they may then be continued, the amount depending on the patient's reaction, until the full course of treatment has been completed. The immunologic response appears to be just as good as when the treatments are given in fewer but larger doses.

It is particularly important that the allergic child be immunized against diphtheria and tetanus so that he will never need the corresponding antitoxins. If tetanus toxoid has been omitted and tetanus antitoxin is indicated, the bovine preparation[29] should be used if available unless the child is allergic to milk or beef. In such cases a despeciated horse serum antitoxin should be used. Despite the so-called despeciation, this serum must be administered with extreme care.

Hypoimmunization against pertussis is important because respiratory allergies are likely to develop in the allergic child. If such a child contracts pertussis, the disease may aggravate a clinical or subclinical respiratory allergy, particularly bronchial asthma. It is important that a phase 1 pertussis vaccine be used and that it be grown on mediums prepared with human rather than with animal blood to avoid sensitization to a foreign protein. Doses of pertussis vaccine should be administered each year until the child is at least 5 years of age. If whooping cough does develop, it should be vigorously combated with human immune globulin.[30] or by the use of hyperimmune human serum.[31]

A child with atopic dermatitis should not be vaccinated against smallpox until the skin is perfectly clear. The reasons for this are, first, that there is danger of multiple external inoculations in scratched-areas and, second, that for a few days after vaccination the virus is carried about in the blood stream and tends to localize in any area of diseased skin. This may produce a generalized vaccinia which may be serious and occasionally disfiguring or even fatal. The length of time which should elapse from the time the skin is clear until vaccination can be safely carried out has never been determined. I generally vaccinate the children during the summer months (except for a minority whose skin is commonly worse in the summer) two or three weeks after the skin is perfectly clear and have never had any complications as a result. It is also important that no fresh vaccinations be made on children from homes in which there are other unvaccinated children with atopic dermatitis. Contact of the skin of these children with a fresh vaccination pustule may produce inoculation, which results in a generalized vaccinia. The contact may also be indirect, e. g., from a soiled towel or washcloth. One death occurred from generalized vaccinia in a hospital of my acquaintance when an infant with atopic dermatitis was bathed in a tub in which a child with a reacting vaccination had just been washed.

In the past few years it has become recognized that Kaposi's varicelliform eruption represents an infection with the virus of herpes simplex (and possibly other viruses) in an eczematous skin. Lynch and others[32] have reported cases in which such infections occurred in infants with atopic dermatitis because of contact with the lesions of herpes simplex in a parent. For this reason contact with persons suffering from herpetic infections should be avoided.

SUMMARY

The orthodox methods of treatment which have proved most successful in the treatment of infantile eczema (atopic dermatitis) are briefly described.

The role of prophylaxis is considered.

The possible importance of house dust as an etiologic factor is discussed.

It is pointed out that warm clothing now made for children from cotton cloth with glass fiber insulation may prove useful for those who are sensitive to wool.

The importance of the routine immunization of children with atopic dermatitis to diphtheria, tetanus and pertussis is stressed. Suggestions are offered in case protection against the two latter has not been conferred.

The necessity of avoiding exposure of children with atopic dermatitis to fresh vaccination lesions and to herpetic lesions in other persons is explained.

ABSTRACT OF DISCUSSION

Dr. Rudolph L. Baer, New York: Dr. Glaser has covered not only the allergic factors but the important nonspecific and nonallergic factors which contribute to this disease. He called attention to the contactant allergenic factors which are frequently overlooked and which may be involved in addition to the inhalant and food factors. The skin of the infant and the young child is more easily penetrated from the outside than the skin of the adult; thus contactants have to be especially considered in these cases. I think that many cases of atopic dermatitis are made worse by exposure to wool; particularly in children wool often plays an important role. The eruption on the wrists so often seen in children with atopic dermatitis is frequently precipitated by the woolen sleeves. It appears probable that these lesions are due to a combined effect of an allergenic action and of friction.

Allergic factors are not the only ones and often not the most important ones in the aggravation of atopic dermatitis. The exact etiology and the mechanism of production of atopic dermatitis are not known. In a certain percentage of cases we cannot even demonstrate any of the features which characterize atopy such as the familial tendency to atopy, eosinophilia, immediate wheal responses to "protein" allergens or passive transfer antibodies. Because of this, nonallergic factors have to be considered. For example, soap, as Dr. Glaser mentioned, is important and should always be avoided, and soap substitutes should be used. Rapid changes in temperature and friction from clothing should be avoided. Excessively strenuous exercises, especially those leading to sweating, should be avoided. In the infant and in the child, as in the adult, itching is the major complaint, and itching is particularly severe in these cases. Stimuli which normally do not cause itching, such as friction, changes in temperature and small particles of clothing, cause severe itching and start up severe itch crises. To handle these cases properly we must take care of these nonallergic causal and contributory factors. In addition the proper topical dermatologic management as outlined by Dr. Glaser is extremely important.

DIGITOXIN INTOXICATION

ARTHUR M. MASTER, M.D.
New York

In his book on poisons, published in 1910, von Jaksch[1] stated:

> Digitalin and digitoxin are frightful cardiac poisons. Their use at the bedside necessitates the greatest care. A single excessive dose of these glycosides invariably results in death from cardiac paralysis in a short time. In clinical toxicology they play a subordinate role. If their use becomes widespread, then, unfortunately, they will become important.

I believe that digitoxin poisoning has now become so frequent an occurrence that it presents a real hazard.

During recent years there has been a resurgence of investigation to find a digitalis glycoside which is stable, of uniform strength, nonirritating to the stomach, readily absorbed from the gastrointestinal tract, quickly eliminated from the body and without excessive cumulative action. Lanatoside C ("cedilanid"),[2] digoxin U. S. P.,[3] strophanthin N. F.[4] and digitoxin U. S. P.[5] have their advocates. This paper will deal solely with digitoxin, including such preparations as "digitaline nativelle," "purodigen," "crystodigen" and the like.

Gold[6] recommended a single full digitalizing dose of 1.2 mg. of digitoxin, followed by 0.2 mg. daily for maintenance. As a result of his reports, particularly those included in the Cornell Conferences on Therapy[5b, c] digitoxin has practically replaced digitalis U. S. P. (digitalis leaf). Although Gold stated that his recommended dosage applied to only three fourths of his series of patients, not only has his average dose been adopted indiscriminately for all patients, but, worse still, much larger doses are prescribed. The dangers attending the administration of digitoxin have been lost sight of, and the drug has been greatly abused.

The following cases of digitoxin poisoning will serve the purpose of this report which is to draw attention to the need of close supervision of patients receiving the drug.

REPORT OF CASES

Case 1.—A man aged 40 was admitted to the Mount Sinai Hospital on May 14, 1946, with a diagnosis of chronic rheumatic heart disease, mitral stenosis and insufficiency and severe heart failure. During the two preceding days he had received 1.8 mg. of digitoxin ("digitaline nativelle"); on the day of admission 0.2 mg. was given twice. He received 0.1 mg. daily for the next four days, that is, until May 19, when the drug was stopped because multifocal premature contractions were observed. He was discharged on June 8. The first electrocardiogram, taken May 17, disclosed auricular fibrillation, a ventricular rate of about 80 per minute, distinct depression of the RS-T segments and inversion of the T waves in the three standard leads. On May 20, complete heart block appeared, with a ventricular rate of 35 to 60 per minute, and bigeminal rhythm due to multifocal premature beats was also present. On May 29, ten days after cessation of therapy, the ventricular rate was still slow, 38 to 75 per minute; an occasional premature beat was present, and the RS-T segments and T waves were only slightly abnormal. Three days later bradycardia and premature beats were still exhibited.

Case 2.—A woman aged 47, was admitted to the Mount Sinai Hospital on Jan. 13, 1946 and died ten days later with severe heart failure. The diagnosis was chronic rheumatic heart disease with mitral stenosis and insufficiency. She was hospitalized because of blurred vision, nausea, diarrhea, restlessness, confusion and semistupor. During the eleven or twelve days prior to admission she had received 6.0 mg. of digitoxin (an average of 0.5 mg. daily), in spite of the fact that she had previously been taking 1½ grains (0.097 Gm.) of digitalis daily.

The first electrocardiogram January 14 revealed auricular fibrillation with bradycardia (55 beats a minute) and distinct depression of the RS-T segment in leads 1, 2 and 4. On January 23, the day of death, nodal tachycardia appeared, and there were many supraventricular premature contractions.

Case 3.—A frail woman, weighing 90 to 95 pounds (40.8 to 43.1 Kg.), was seen in consultation on Aug. 14, 1946 because of recurrent attacks of pulmonary edema. She had had an acute coronary occlusion seven years previously and was moderately hypertensive. She had received three to five doses of 0.4 mg. of digitoxin intravenously within twenty-four hours. The patient became nauseated and vomited continuously, but the pulmonary edema cleared up. She died the following day.

Case 4.—A man aged 53 was admitted to the Mount Sinai Hospital on May 10, 1946, because of severe heart failure. Auricular fibrillation (cause unknown), pulmonary edema and pulmonary infarct of the lower lobe of the right lung were present. On the first day he received 1.8 mg. of digitoxin and the next day 0.4 mg., a total of 2.2 mg. within thirty hours. He died on the fourth day, May 13.

The electrocardiograms, taken May 10 and 11, disclosed auricular fibrillation with a ventricular rate of 200 beats per minute. On May 12, ventricular tachycardia had appeared, and electrical alternans and bidirectional ventricular premature beats were present. On May 13, the day the patient died, the auricular fibrillation reappeared, and the ventricular rate was approximately 180 beats a minute.

Case 5.—A man aged 38 had received 0.1 mg. of digitoxin ("purodigin") daily during January 1946 as a prophylactic measure against paroxysmal auricular flutter. He weighed 150 pounds (68 Kg.). When I saw him on February 16, he complained of yellow vision, abdominal cramps and bouts of diarrhea. The drug was discontinued and these symptoms disappeared. During the next two months digitoxin ("digitaline nativelle") was given intermittently in the same dose, 0.1 mg. daily, always with a return of visual and abdominal complaints. Electrocardiograms revealed auricular flutter, auricular tachycardia or partial heart block with dropped beats, but with a ventricular rate between 120 and 150 per minute.

Case 6.—A woman aged 59 had been operated on in 1945 for intestinal carcinoma. On Nov. 8, 1946 she had onset of pain in the upper part of the abdomen, which was interpreted as due to coronary disease. She was placed under treatment with digitoxin ("crystodigin") for one week, but the dose of this drug could not definitely be ascertained. There developed paroxysmal auricular fibrillation for one day, and the drug was stopped. On November 24 there was recurrence of pain. Although the patient weighed only 95 pounds (43.1 Kg.), she received 0.2 to 0.4 mg. of digitoxin daily. She became restless, disoriented and nauseated and vomited repeatedly. Leukocytosis, with a count of 11,000 to 13,000, developed, with a temperature of 102 to 102.5 F. Neurologists were called in for consultation but could find no evidence of organic cerebral involvement.

I saw the patient on December 12 and made a diagnosis of digitalis intoxication with digitalis psychosis. There was no evidence of heart failure or cardiac enlargement. The rhythm was irregular and rapid. Administration of the digitoxin was discontinued, but evidence of poisoning persisted in the electrocardiogram for three weeks.

The electrocardiogram taken on November 28 (fig. 1 *A*) showed sinus tachycardia, with a rate of 155 per minute, RS-T depressions and inversions of the T waves in leads 1, 2 and 4. On December 12 (fig. 1 *B*) there was partial heart block with dropped beats, i.e., Wenckebach periods, the ventricular rate being 115 to 120 a minute, and RS-T depressions and inversions of the T waves in leads 1, 2 and 4. Digitoxin was discontinued. The tracing of December 15 (fig. 2 *A*) still revealed a 2:1 heart block with dramatic depressions of the RS-T segments and pronounced inversions of the T waves in all leads. On December 18 (fig. 2 *B*) sinus tachycardia alternated with 2:1 heart block, but the RS-T depressions and inversions of the T waves were not quite so pronounced. On December 28 (fig.

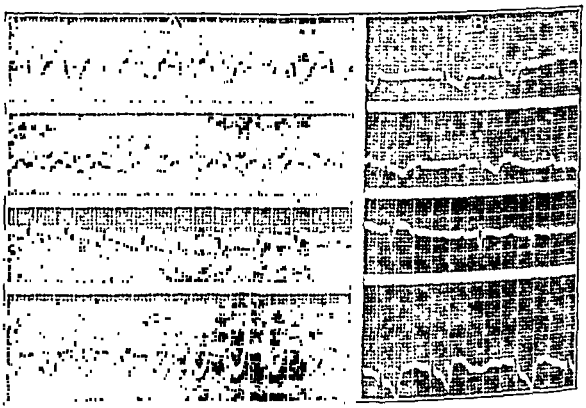

Fig. 1.—The tracings in this figure and in figures 2 and 3 are those of a woman aged 59, weighing 95 pounds (68.1 Kg.) with digitoxin intoxication. *A* (11/28/46), after administration of digitoxin, 0.2 to 0.4 mg. daily for five days, showing sinus tachycardia, with a rate of 155 per minute, and depression of the RS-T segments in leads 1, 2 and 4 and inverted T waves. *B* (12/12/46), after administration of digitoxin, 0.2 to 0.4 mg. daily for nineteen days. There were partial heart block (Wenckebach periods) with dropped beats, a ventricular rate of about 115 per minute and depression of the RS-T segments with inversions of the T waves in leads 1, 2 and 4. Digitoxin was discontinued.

---

6. Gold.[5c] Conferences on Therapy: Use of Digitalis, New York State J. Med. **42:** 2043 (Nov. 1) 1942; Digitalis Versus Digitoxin, ibid. **45:** 1676 (Aug. 1) 1945.

(3*A*) sinus tachycardia, with a rate of 120 a minute, was present, with the T wave semi-inverted in leads 1 and 2. On January 13 (fig. 3*B*) the electrocardiogram was normal with regular sinus rhythm (rate, 95 a minute).

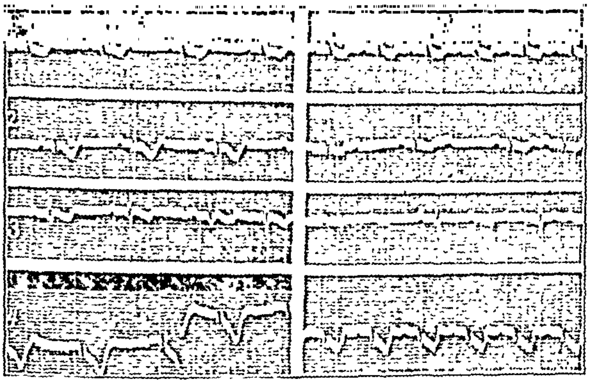

Fig. 2.—*A* (12/15/46), 2:1 heart block, with depression of the RS-T segments and inversions of the T waves in all leads. *B* (12/18/46), sinus tachycardia alternating with 2:1 heart block. The depressions of the RS-T segments and inversions of the T waves are not quite so pronounced.

Subsequent observation of the patient confirmed the impression that she did not have any organic heart disease. Thus, the cerebral symptoms and the arrhythmias were unquestionably produced by the digitoxin, and not by myocardial disease.

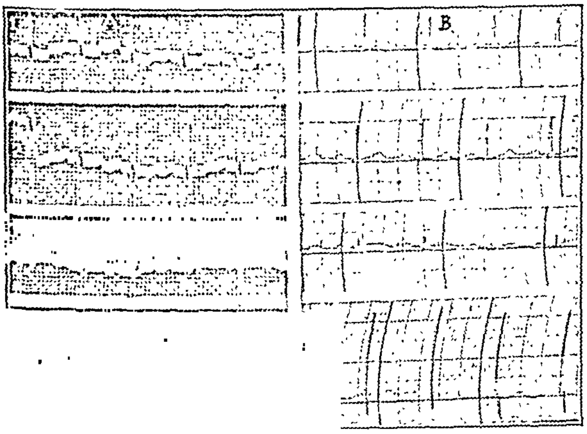

Fig. 3.—*A* (12/28/46), sinus tachycardia, with a rate of 120. The T waves in leads 1 and 2 are still semi-inverted. *B* (1/13/47), normal sinus rhythm, with a rate of 95. The tracing is now normal.

Case 7.—A woman aged 71 was admitted to the Mount Sinai Hospital on May 8, 1946 for hypertensive vascular disease with heart failure. Digitalis had been prescribed before her admission, but the type and quantity of the drug were not ascertained. Although the patient weighed only 96 pounds (43.5 Kg.), she received 0.1 mg. of digitoxin daily, and occasionally 0.2 mg. Anorexia, nausea and vomiting developed. The drug was finally stopped on June 14. She was discharged on June 18.

The electrocardiogram on May 10 disclosed inverted T waves in lead 1 and supraventricular premature beats. The rate was 80 a minute. On June 12 there were numerous multifocal and bidirectional premature beats, with a rate of 150 a minute.

Case 8.—A woman aged 60 was admitted to the Mount Sinai Hospital on Jan. 31, 1947 and died February 8. On admission she had severe epigastric pain, nausea and vomiting. Examination revealed mild fever, moderate leukocytosis, hypertension and, on the seventh day, definite evidence of heart failure. The electrocardiogram was typical of acute coronary occlusion with infarction of the anterior wall. Injections of mercury being unsuccessful, on the eighth day 0.8 mg. of digitoxin was administered intravenously, and the patient died one minute later.

In this case the patient's acutely damaged myocardium undoubtedly increased her susceptibility to digitoxin.

Case 9.—A man aged 59 had a history of acute coronary occlusion nine years prior to the present admission and heart failure six years later. Although he had received digitalis and mercurial injections, this medication was discontinued six weeks before his admission to the Mount Sinai Hospital, on Feb. 25, 1947.

He was dyspneic and orthopneic, with pulmonary congestion and venous distention, enlargement of the liver and edema of the ankles. On the evening of admission he received 1.2 mg. of digitoxin orally and 2 cc. of meralluride N. N. R. ("mercuhydrin") intramuscularly. An electrocardiogram taken the following day revealed complete heart block and auricular tachycardia, with an auricular rate of 150 to 155 and a ventricular rate of 80 per minute. Furthermore, there were numerous ventricular premature contractions, often producing bigeminy. Clinically, the patient exhibited no manifestations of digitalis poisoning, but, of course, the digitoxin was discontinued. On February 27 the auriculoventricular dissociation was still present, with periods of 2:1 block. Sinus rhythm was observed the next day, but the P-R interval was prolonged to 0.28 second.

In this case the single oral dose of 1.2 mg. of digitoxin was excessive. The only evidence of digitoxin intoxication appeared in the electrocardiogram.

The symptoms of digitoxin poisoning, as observed in the foregoing cases, do not differ from poisoning with other types of digitalis. Since digitoxin has a definite cumulative action,[7] the toxicity persists longer than that after other preparations of digitalis. Hence, great caution is necessary in its administration. If the method outlined by Gold and his co-workers for the use of digitoxin were followed in detail, the adverse effects so frequently encountered would probably be lessened. These authors pointed out that their dose was an average one and did not apply to all patients, a fact often overlooked. Relatively larger doses of digitoxin than of digitalis U. S. P. (digitalis leaf) are prescribed because the dose of the former seems so small. Digitoxin is prescribed in decimals of a milligram, just one-thousandth the strength of the dose in which digitalis U. S. P. is given—namely, in decimals of a gram.

Although the danger of the relatively long latent period and cumulative action or slow dissipation of digitoxin is real, I believe that many, if not all, of the untoward effects of this drug have resulted from its careless, haphazard use. The dosage of 1.2 mg. as a single average digitalizing dose and of 0.2 mg. for maintenance has often been indiscriminately applied to patients regardless of weight, without proper surveillance of the patient and without awareness of the dangers involved in using the drug. A patient weighing only 95 pounds (43.1 Kg.) is often given the same dose —0.2 mg. daily—as is one who weighs 150 to 225 pounds (68 to 102 Kg.). In this regard it is probably significant that the Varick Company, which markets "digitaline nativelle," used to advertise 0.1 mg., and not 0.2 mg., as the average daily maintenance dose, but recently has altered its advertisement and gives the maintenance daily dose as varying between 0.05 and 0.2 mg. Unless each patient is treated individually and the proper dose carefully determined, it is safer to use digitalis U. S. P. than digitoxin.

SUMMARY

Digitoxin has practically replaced digitalis U. S. P. (digitalis leaf), but the dangerous aspects of its administration have been disregarded and digitoxin intoxication has become frequent.

---

[7] DeGraff and Batterman.[2a] Hoffmann, A.: Funktionelle Diagnostik und Therapie der Erkrankungen des Herzens und der Gefässe, Wiesbaden, J. F. Bergmann, 1911, p. 412.

Clinical observations confirm the pharmacologic fact that digitoxin has the greatest cumulative action (slowest dissipation) of all the glycosides.

Nine cases of digitoxin intoxication are reported. The symptoms included nausea, vomiting, blurred and yellow vision, abdominal cramps, diarrhea, restlessness, mental confusion, disorientation and psychosis. Premature contractions, bigeminy, trigeminy and multifocal bidirectional premature beats; tachycardias of auricular, nodal and ventricular origin with rapid ventricular rates; auricular fibrillation and auricular flutter; partial and complete heart block, and electrical alternans were observed.

Since the therapeutic dose of all digitalis drugs is 50 to 60 per cent of the toxic dose, a relatively small additional amount may be sufficient to cause a toxic reaction. The administration of digitoxin, like that of any other preparation of digitalis, because of the variability in absorption, excretion and therapeutic effect, is an individual experiment.

The dosage of 1.2 mg. as a single digitalizing dose and of 0.2 mg. for maintenance has often been applied indiscriminately to patients regardless of weight, without proper surveillance of the patient and without awareness of the dangers involved in using the drug. It must be remembered that the daily maintenance dose of digitoxin varies from 0.05 to 0.2 mg.

Council on Physical Medicine

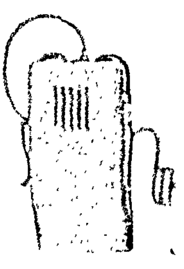
The Council on Physical Medicine has authorized publication of the following report. Howard A. Carter, *Secretary.*

WESTERN ELECTRIC HEARING AIDS, MODELS 65 AND 66, ACCEPTABLE

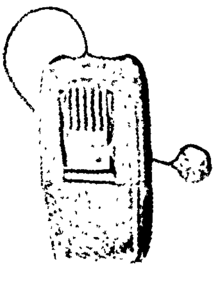
Manufacturer: Western Electric Company, Inc., 120 Broadway, New York 5.

MODEL 65

As exemplified by instrument A 0023, Model 65 is a self-contained hearing aid encased in plastic. A hinged cover gives access to the battery compartment, which is at the back of the case. It is connected to the magnetic receiver by a plastic-covered cord with plugs at both ends. Two receivers were supplied.



WESTERN ELECTRIC MODEL 65



WESTERN ELECTRIC MODEL 66

Two wheel-type controls are placed at the top of the instrument. One is the volume control, the other is a combination switch tone control and gives three tone settings. On each side of the instrument wearing clips are so placed that the opening of the microphone will be above the edge of the pocket.

The following data were obtained by a Council investigator: *Dimensions and Weight.*—Dimensions: Length 10.9 cm. (4⅓ inches); thickness 2.1 cm. (8⁄10 inch), and width 6.2 cm. (2½ inches). Weight: 172 Gm. (6 ounces).

Battery Data.—Usable Batteries: A, 1½ volts; B, 15 volts.

Battery Drain Measurements

Battery	Voltage	Current
A	1.4 volts	42 milliamperes
B (Quiet)	15 volts	0.46 milliampere
(Squealing)	15 volts	0.24 milliampere

Acoustical Gain.—Measurements were made of the acoustic gain in decibels. This is the decibel difference between the sound pressure at the face of the microphone of the instrument and the pressure produced by the receiver in the 2 cc. coupler. The pressure at the face of the microphone was held at approximately 55 decibels above zero level for these measurements (55 db. above 0.0002 dyne/sq. cm.). Following is a tabulation of typical acoustical gains:

		Frequencies							
Volume	Tone	256	512	1,024	1,200	2,250	3,100	4,096	Receiver
Full	1 dot	13	23	36	37	47	35	17	724 B
Full	3 dots	28	39	47	48	53	40	20	724 B
Full	3 dots	30	42	54	60	55	42	25	724 A

Below are approximate values of maximum sound pressure levels (at four frequencies) set up in the 2 cc. coupler with the volume set for full gain and tone setting at 3 dots:

Frequency	Input Level	Maximum Output Level
600 cycles	80 db.	124 db.
1,024 cycles	70 db.	121 db.
1,200 cycles	70 db.	129 db.
2,048 cycles	65 db.	116 db.

Intelligibility tests were made with a person of normal hearing seated inside a booth giving about a 30 decibel sound reduction. The speaking person was outside the booth using normal speaking voice. Score made with the Harvard number 9 lists under these critical conditions was 70 per cent.

MODEL 66

As exemplified by instrument B 1165, Model 66 is a self-contained hearing aid encased in plastic. The removable lower half of the case is the battery housing. Connections with the magnetic receiver are by a plastic-covered cord with plugs at both ends. Two receivers were supplied with the instrument.

At the top of the case are two wheel-type controls, of which one is the volume control. The other is a combination switch tone control giving three tone positions. A wearing clip on the front of the case is placed so that the opening of the microphone will be above the edge of the pocket.

Dimensions and Weight—Dimensions: length 12.5 cm. (5 inches); thickness 3.8 cm. (1½ inches), and width 6.5 cm. (2¾ inches). Weight: 250 Gm. (9 ounces).

Battery Data.—Usable Batteries: A, 1½ volts; B, 22 volts.

Battery Drain Measurements

Battery	Voltage	Current
A	1.35 volts	42. milliamperes
B (Quiet)	21.8 volts	0.72 milliampere
(Squealing)	21.8 volts	0.52 milliampere

Acoustical Gain.—Measurements were made of the acoustic gain in decibels. This is the decibel difference between the sound pressure at the face of the microphone of the instrument and the pressure produced by the receiver in the 2 cc. coupler. The pressure at the face of the microphone was held at approximately 55 decibels above zero level for these measurements (55 db. above 0.0002 dyne/sq. cm.). Following is a tabulation of typical acoustical gains:

		Frequencies							
Volume	Tone	256	512	1,024	1,200	2,250	3,100	4,096	Receiver
Full	1 dot	14	26	32	34	41	40	34	724 C
Full	3 dots	44	51	50	50	50	47	40	724 C
Full	3 dots	49	58	67	72	63	48	31	724 A

Below are approximate values of maximum sound pressure levels (at four frequencies) set up in the 2 cc. coupler with the volume set for full gain and tone setting at 3 dots.

Frequency	Input Level	Maximum Output Level
600 cycles	75 db.	129 db.
1,024 cycles	65 db.	130 db.
1,200 cycles	65 db.	135 db.
2,048 cycles	70 db.	123 db.

Intelligibility tests were made with a person of normal hearing seated inside a booth giving about a 30 decibel sound reduction. The speaking person was outside the booth using a normal speaking voice. Score made with the Harvard number 9 lists under these critical conditions was 60 per cent.

The Council on Physical Medicine voted to include the Western Electric Hearing Aids, Models 65 and 66, in the list of accepted devices.

MAICO STETHETRON ACCEPTABLE

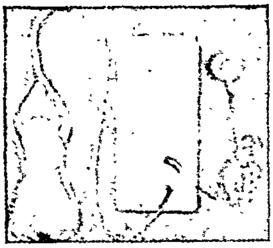
Manufacturer: Maico Company, Inc., 21 North Third Street, Minneapolis.

The Maico Stethetron consists essentially of three parts: (1) a receiving or auscultating part intended to be placed in contact with the patient's chest or other structure to be auscultated, (2) a case housing the amplifying apparatus and (3) the familiar V shaped binaural arrangement of tubing to convey the amplified sounds to the physicians' ears. The three parts are all contained in a leather carrying-case whose over-all dimensions do not exceed 21.2 by 9.8 by 4.4 cm. (8⅜ by 3⅞ by 1¾ inches). The amplifying apparatus is said by the company to include tubes which are high gain hearing aid pentodes, and the output tube is stated to be capable of delivering 10 milliwatts of audio power.

The apparatus as a whole may be described as an electronic stethoscope and is designed to amplify the sounds ordinarily heard in auscultation; it is intended to aid physicians who are hard of hearing and students who are learning to auscultate.

The pickup is designed primarily to change cardiac and pulmonary sounds into electrical voltages by means of a piezoelectric crystal. The pickup is stated to be highly sensitive to vibrations produced by body sounds but relatively insensitive to airborne or acoustical vibrations. The electric impulses are amplified and then converted into acoustical vibrations by a dynamic transducer. The output of the transducer is fed into a binaural headset so that the amplified heart sounds reach the physicians' ears in the same manner as they would through an ordinary stethoscope.

The electrical power gain of the Stethetron is stated to be about 90 decibels. The power is supplied by an A battery of 1½ volts and a B battery of 45 volts. The average current drain on the A battery is about 80 milliamperes, and with normal use it is expected to last about one hundred hours. The average current drain on the B battery is about 2 milliamperes, and with normal use it is expected to last about two hundred and fifty hours.



THE MAICO STETHETRON.

Since the impairment of hearing is generally not uniform through the range of audible frequencies, and since the pattern of impairment varies from one user to another, the Stethetron is provided with a tone control, or emphasis filter, giving six possible positions. The green dot position of the emphasis filter attenuates the lower frequencies, thereby emphasizing sounds of systolic and diastolic murmurs. The red dot position disconnects the emphasis filter entirely, giving a fairly uniform response from 50 to 1,000 cycles per second, for listening to peristaltic sounds and respiratory sounds. The blue dot position emphasizes frequencies around 250 cycles per second. The yellow position emphasizes frequencies around 175 cycles per second. The white dot position emphasizes frequencies around 125 cycles per second, suitable for listening to presystolic murmurs. The black dot position emphasizes frequencies around 90 cycles per second and is used for systolic and diastolic sounds.

Additional possibilities of this instrument are as follows: 1. A booster unit, consisting of a battery-operated amplifier, can be connected to permit simultaneous listening by from six to twelve physicians or students. 2. A record-playing attachment is available. 3. The output terminals of the Stethetron can be connected to the input terminals of an oscilloscope. 4. It is possible to connect the instrument to a loudspeaker for classroom purposes. 5. Permanent records can be made by using direct-inking equipment, tape recorders and wire recorders.

The device was used and studied by a number of physicians, who submitted reports to the Council. The consensus was that the instrument is effective as an aid to physicians who are hard of hearing. While there was no doubt expressed as to its value as a teaching appliance when used in conjunction with some of the aforementioned accessories, there was disagreement as to its value in teaching actual auscultation to the medical student or in discriminating (by the use of the tone control, or emphasis-filter) between sounds of different quality.

The Council on Physical Medicine voted to include the Maico Stethetron in its list of accepted devices.

Clinical Notes, Suggestions and New Instruments

CONTACT DERMATITIS DUE TO "FINGER PAINTS"

NORMAN TOBIAS, M. D.
St. Louis

The literature does not disclose any reports of contact dermatitis due to "finger paints." Finger paints are creamy paints which are sold in sets of six colors and which when applied to a special wetted paper with the fingers or forearms result in an unusual tinctorial effect. The designs or patterns may be changed by blending the various colors. The product is popular with children and has been used by adults as a form of occupational therapy. A case is reported in a boy who had contact dermatitis from the paint on his face, fingers and forearms. The manufacturer did not reply to the letter requesting information regarding the formula, so that the particular sensitizer is not known at this time.

Some cases are probably being diagnosed as poison ivy dermatitis or even erysipelas by general practitioners who are unfamiliar with this contactant.

Report of Case

J. K., aged 8, had an acute erythematovesicular dermatitis in the interdigital spaces of his right hand four days after first using the finger paint; the dermatitis appeared on the dorsal surface the next day. Three days later a similar eruption, patchy and linear in character, appeared on the right cheek, midforehead and left forearm. Mild itching was present. The paints were used about fifteen minutes daily. Although the preparation is easily washed off with water, the boy had apparently rubbed his face with his fingers, which explains the eruption on the cheek and forehead. The patch on the left forearm was caused by using that part to rub the paints on the paper.

A patch test with the red paint was applied to the left arm the day after consultation. Within twenty-four hours, there was a 3 plus reaction. Patch tests on 3 normal controls were negative in result. Treatment consisted of a mild astringent lotion, with complete recovery within a week.

Summary and Conclusions

The exact sensitizer or sensitizers in the finger paint were not determined. It is possible that a plasticizer may be causative. Schwartz[1] stated that "a great many pigments are used in paint but they are rarely the cause of dermatoses."

From the Department of Dermatology and Syphilology, St. Mary's Group of Hospitals, St. Louis University School of Medicine, Dr. G. V. Stryker, Director.

The absence of the compositors from their work continues. This issue of THE JOURNAL has been prepared in part by the use of Vari-Typer machines.

THE BROOKINGS REPORT ON COMPULSORY HEALTH INSURANCE

When the Congress passed the Social Security Act, provisions were made for the regular expenditure of governmental funds in the study of medical care. The misuse and abuse associated with such expenditures under the administration of Isidore Falk, who is responsible to Mr. Altmeyer and the Federal Security Administrator, has been so frequently described that repetition would be boresome. What should have been a scientific investigative agency has been perverted into a group who manipulated statistics and assembled data for propaganda purposes. After many years investigations have been made by congressional committees and other groups. Eventually, no doubt, this particular " chicken will come home to roost. "

Recently the Senatorial Subcommittee on Health of the Senate Committee on Labor and Public Welfare requested the Brookings Institution, a nonprofit agency which has functioned for many years on an independent basis, to make a study of compulsory health insurance, as the committee was concerned with several bills on this subject. The conclusions and recommendations have been furnished to the Senate committee. The Brookings Institution decided, because of the wide public interest in the subject, to make the full study available in printed form. The report is made by Dr. George W. Bachman and Dr. Lewis Meriam. Dr. Bachman has had wide experience in experimental medicine and public health on the faculties of Chicago, Johns Hopkins and Columbia universities and for eleven years directed the School of Tropical Medicine in Puerto Rico. Dr. Meriam's previous work in the Census and Children's bureaus, in a survey of the Indian Administration and in many studies of state government, relief and social security, indicates his qualification for the task. With these two leaders several staff members of great repute were associated. Every physician should secure and study this important book.

The report defines the two major plans now under consideration by the national government: the grants-in-aid plan and the compulsory health insurance plan. First to be answered is the common question, " How bad are health conditions in the United States?" Comparisons are made with other countries as well as comparisons between the individual states. The draft data have been studied, and consideration has been given to the effects of various systems on the practice of medicine and on the cost of medical care. The investigators were also concerned with the availability of medical personnel, with administrative costs and many related problems. As a result of the analysis of a vast amount of carefully developed evidence, positive answers are made to many controversial questions.

A study of mortality rates throughout the world has warranted three conclusions: (1) that the United States had made enormous advances since the turn of the century; (2) that it is now among the most healthful nations of the world, and (3) that its white population is fast approaching, if it has not already reached, the point at which the rate of advance will be much retarded. The significance of these conclusions cannot be overestimated.

Here is the answer to the continuous reiteration by propaganda groups that various nations are superior to the United States in maternal and infant mortality, or that there are great areas of our nation without adequate medical care, or that we are clearly outclassed by New Zealand or Denmark or some other small country that either has a homogeneous population or does not count its native population. The figures indicate that our white population has reached such a high record as regards its health that further reduction in death rates is going to be exceedingly difficult and perhaps impossible.

Again it becomes clear that the mortality rates among the nonwhite persons are unfavorable. However, the Brookings report brings out that more and better medical care is not the only requirement. In fact the advantages to be gained by more and better medical care

are minor as contrasted with improvements in economic, educational, cultural and social conditions needed by our colored populations.

In this Brookings report is another analysis of the Selective Service statistics. For some years the proponents of compulsory sickness insurance and state medicine have been reiterating to the point of monotony the argument that Selective Service statistics indicate that we are a nation of weaklings with millions of young men incapable of rendering military service and with millions suffering from preventable and curable defects. A careful study by Friedman in Washington was the first important and devastating blow to these arguments and to the parrot-like mutterings made by the inside ring of the Committee on the Nation's Health that used them for propaganda. Now comes this study of the Brookings Institution with an analysis which proves that the Selective Service statistics actually demonstrated the exceedingly high quality of medical care in our country. The Selective Service statistics are not helpful in any consideration of proposals to alter arrangements for the provision of individual medical care. A special chapter on the subject comes to a conclusion worthy of quotation:

> Medical care, however adequate, cannot prevent certain diseases, conditions, or impairments. It cannot invariably effect a cure or restoration that will bring the individual up to or above the minimum standard for rigorous physical activity such as that used for the armed forces. It may and does enable the victims of accidents and many diseases to live and to support themselves and those dependent upon them. It seems almost certain that the better the medical care in a country the larger the number of its people who will be living despite accidents, illnesses, and impairments. A Spartan program of eliminating the physically and mentally unfit would yield a higher percentage suitable for military service than would a program of doing everything possible through medical care to preserve life and to enable persons to make that life worth while, despite conditions that make them ineligible for military service.

The attention of the Brookings group is turned to some of the so-called health surveys that have been made since 1930 with a view to determining the nature, distribution and cost of medical care in the United States. One analysis concerns the investigation made under the Committee on the Costs of Medical Care, which have constituted a sort of bible for most of the proponents of compulsory sickness insurance. There was no scientific objective standard of what constituted an illness or a condition which required treatment which was applied to all regardless of income. Attention is also given to the National Health Survey which was conducted by the Works Progress Administration under the auspices of the United States Public Health Service. A single sentence seems to define the failure of that survey for all practical purposes. The sentence concerns persons with incomes under $1,000 or those on relief: "It is difficult to determine whether their poverty was due to their illness or their illness due to their poverty."

The Brookings report also sets forth the basic arguments for and against voluntary sickness insurance and compulsory insurance. Its conclusions are so important that they are here quoted in full:

> 1. Probably no great nation in the world has among its white population better health than prevails in the United States. A few small homogeneous countries, such as New Zealand with respect to its white population, are slightly ahead of the United States, as a whole, but certain states of the United States with larger populations equal them.
>
> 2. It is apparent that the United States under its voluntary system of medical care has made greater progress in the application of medical and sanitary science than any other country. This progress is now reflected in low mortality and morbidity rates of infectious diseases and in increased life expectancy. There is every reason to believe that these trends will continue unabated under our present system of medical care.
>
> 3. The nonwhites in the United States have materially poorer health than the whites, but the evidence does not indicate that this condition is primarily or even mainly due to inadequacy of medical care.
>
> 4. The advances in health among both the whites and the nonwhites that have been made in the United States in the past four decades do not suggest basic defects in the American system.
>
> 5. Although the statistics resulting from the administration of the Selective Service Act—the so-called draft statistics—have been widely used to show bad health among the American people and the need for revolutionary changes in arrangements for medical care of individuals, they are unreliable as a measure of the health of the nation and cannot be used to show the extent of the medical needs of the country as a whole.
>
> 6. Present medical care in the United States compares favorably with that which existed in other leading nations prior to the second World War.
>
> 7. The conditions in extremely poor rural areas that lack the resources to support adequate public services, such as health work, education, and highways, cannot be satisfactorily solved by subsidies. This problem calls for a radically different approach, either bringing in new or improved economic activities or getting the people to more favorable and administratively less expensive areas. This condition has been accentuated by the emigration of youth from these areas to urban communities.
>
> 8. The United States has some individuals and families not possessed of the resources to enable them to pay for adequate medical care. In the future, as in the past, provision must be made for them through public funds or philanthropy. The evidence suggests that many of them are elderly, impaired or underendowed or are widows or deserted women or their dependents. It is doubtful that they could be effectively covered by compulsory insurance because they would lack the means to attain and maintain an insured status. The large majority

of American families have the resources to pay for adequate medical care if they elect to give it a high priority among the several objects of expenditure. The issue is not whether they can afford medical care but whether they should be compelled by law to pool their risks and to give payment for medical care a top priority. The major alternative for people with ability to pay is to leave them free to determine for themselves what medical care they desire and whether they will pool their risks through voluntary arrangements.

9. Compulsory health insurance would necessitate a high degree of governmental regulation and control over the personnel and the agencies engaged in providing medical care. This field of regulation and control would be far more difficult than any other field previously entered by the government, and past experience with governmental regulations and control in the United States causes doubt as to whether it encourages initiative and development.

10. The problem of eliminating politics from government administration is extremely difficult. It does not seem probable that politics could be eliminated from medical care supplied under a governmental system.

11. Compulsory insurance would inject the government into the relationship between practitioner and patient. A real danger exists that government actions would impair that relationship and hence the quality of medical care.

12. The administration of compulsory insurance would require thousands of government employees for accounting, auditing, and inspection and investigation.

13. The cost of medical care presumably would increase because of (*a*) administrative expenses; (*b*) the tendency of insured persons to make unnecessary and often unreasonable demands upon the medical care services; and (*c*) the tendency of some practitioners and agencies to use the system for their own financial advantage.

14. The adoption of compulsory insurance would not immediately make available adequate medical service for all, because there are not at present the facilities nor a sufficient number of trained and experienced physicians, dentists, and nurses to meet the demand which would result from compulsory insurance.

15. Proposals for compulsory insurance provide for payment of practitioners under one or all of three methods: (*a*) fee for service, (*b*) per capita, or (*c*) salary. Use of the fee-for-service device represents the minimum degree of socialization, but it is administratively difficult. Administrative difficulties would probably result in the adoption of the per-capita system which represents a higher degree of socialization or even in the salary system which represents practically complete socialization. It seems questionable whether a country which once embarks on compulsory insurance can turn back but must attempt to remedy defects by more complete government control and administration.

As a result of these studies and the conclusions reached, the report of the Brookings Institution says that the national government would be wise to leave to the individual states the question of whether compulsory health insurance is to be adopted or whether the provision of professional services is to be left in the realm of free enterprise. They believe it is highly improbable that experimentation with a variety of plans will ultimately develop a single pattern applicable to all sections of the country. For the time being, the report suggests, the national government and many of the state governments may well devote their resources and energies to:

a. Research and developments in the fields of public health.
b. Health education at the school level.
c. Teaching of preventive medicine.
d. Assisting in the acquisition of physical facilities and training of personnel.
e. Providing systematic care for the indigent and the medically indigent.

Especially important, however, is a recommendation from the point of view of the proper place of government in educating the public with regard to medical care. Recommendation no. 3 says:

> From the standpoint of public relations, governments might be well advised to leave adult educational campaigns for the control and prevention of disease to the national, state, and local voluntary organizations, which have been able to enlist the active cooperation of leading laymen in most sections of the country. It must be remembered that good health is not exclusively a matter of medical care; it also impinges upon causative factors that are nonmedical, such as food, shelter, vice and crime, transportation, and industry. Its maintenance depends also upon the intelligence, interest, and cooperation of individuals, families, and local communities.

Finally, an analysis is made of the changes that have taken place in the United States since 1932 in medical care, and here is the concluding paragraph:

> The experience of the United States since 1932 seems to have demonstrated the wisdom of these recommendations of the majority of the members of the Committee on the Costs of Medical Care. It would seem unwise at this time to substitute for these developments a system of compulsory health insurance by national law which would have the unfortunate tendency to freeze policies and eventually retard medical progress.

When the original report of the Committee on the Cost of Medical Care appeared in 1932 THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION urged evolution. The majority of the Committee on the Cost of Medical Care did not at that time recommend compulsory sickness insurance although they did say that " such a step may ultimately be necessary and desirable in some states."

Notwithstanding the recommendations of even the majority of the Committee on the Cost of Medical Care, agencies devoted to propaganda have consistently and persistently since that time urged a nationwide state-controlled compulsory sickness insurance. Even at this very moment these agencies are vociferous in their arguments and have the support of President Harry S. Truman. Moreover, as has already been mentioned, the agency for the study of medical care in the Federal Security Agency has been from the first an agency of propaganda rather than an agency for scientific study. The report on " The Issue of Compulsory Health Insurance " by George W.

Bachman and Lewis Meriam, published by the Brookings Institution, should bring a blush of shame to the cheeks of even these hardened advocates of government medicine. Surely they will recognize now the difference between a scientific objective study of dependable evidence and the kind of promotional publicity that they have been turning out in pseudo-scientific documents since they first began collecting a living from government sources.

Current Comment

PSYCHOTHERAPY

Several much discussed and little understood basic theories underlying psychotherapy have recently been discussed by Karpman,[1] who calls attention to three concepts. Conventional psychiatry still emphasizes the physical approach and looks for physical factors which may explain or be responsible for so-called functional mental diseases. Psychopathology also moves essentially along the level of conventional psychiatry, emphasizing the importance of personality without giving clues to the origins of personality make-up and resources. The psychodynamic approach works primarily with the patient as an individual, centering the entire weight of treatment on him rather than on the external environment. The psychodynamic approach cannot be satisfied with mere observation and interview but goes beyond in an attempt to find basic causations. All that is obtained on a conscious or intellectual basis is disregarded, and only unconscious material obtained through free association and dream analysis is considered. Minor psychotherapy is practiced chiefly by physicians who are committed to the organic approach and who are unwilling or unable to see the psychodynamics back of mental disease. They fail to understand the manifestations of the unconscious, the psychic mechanisms and processes and the role that symbolization plays in our lives. Major psychotherapy (psychoanalysis) presents fundamental differences from other psychiatric disciplines, being oriented in psychodynamics which recognizes the unconscious as the most dynamic aspect of life. Psychodynamics demonstrates how the principles of homeostasis are applied in our psychic life, as instanced by the pleasure-pain principle, the elucidation of emotions as energy manifestations flowing out of instincts and the importance of increasing depth of insight. Finally, psychodynamics is stated to be in a position to make definite contributions to other sciences such as physics, pathology, sociology and the humanities in general. Frequently the advancement of knowledge gains by review and analysis of current practices. The contribution of Karpman will inspire psychiatrists to evaluate more closely the technics they now employ.

CHEMOTHERAPY OF LEUKEMIA

The cytotoxic action of urethane (ethyl carbamate) and of mustard gases in animals led to experiments with these substances in animal tumors and the treatment of human leukemia and other neoplastic diseases. Many reports on the results of this chemotherapy have been published.[1] Hirschboeck and associates[2] have reviewed the clinical reports and submitted an instructive discussion. In chronic myeloid leukemia and to a lesser degree in lymphatic leukemia urethane in proper doses decreases not only the lymphocytes in the blood but also the size of lymph nodes, spleen and liver. Studies are lacking of these organs and of the marrow in patients treated with urethane. Thus far apparent cure of leukemia by urethane has not been recorded. The reduction in white blood cells, especially lymphocytes, and other substantial palliative effects appear to have been temporary only.[3] The use of urethane is not without danger, as yet the best dosage and methods of administration under different conditions have not been worked out fully. Like arsenical compounds, urethane may be of use as an adjunct to roentgen therapy in myelogenous leukemia. With nitrogen mustard gas Alpert and Peterson[4] obtained results against Hodgkin's disease and lymphosarcoma which they classified as spectacular, fairly good and poor. In the favorable cases recurrence was common. The remissions under chemotherapy in leukemia, lymphosarcoma and other cancers are of great scientific interest and present openings for further research. Certainly the actions of nitrogen mustard and also of urethane as adjuncts to roentgen treatment in Hodgkin's disease invite careful investigation. From a review of clinical and experimental work with the nitrogen mustards Rhoads[5] concludes that in the nitrogen mustards there is available a chemical tool by which can be obtained in Hodgkin's disease and certain cases of lymphosarcoma results about as good as, but not much better than, those obtained by x-ray. Perhaps new chemical agents will be found which may be more effective than those now under study.

RURAL SCHOOL HEALTH PROGRAM

DR. G. F. MOENCH, Hillsdale, Michigan, Director, Hillsdale County Health Department; *Chairman, National Advisory Committee,* Health and Summer Round-up for Parent-Teachers Association, Presiding.

The School Lunch Program

MRS. J. LANING TAYLOR, Director, Educational Department, the National Cooperative Milk Producers Federation, Washington, D.C.: Every nutritional survey in the past decade has shown that many school children are victims of malnutrition. Federal aid for school lunches was first made available not as a nutritional program but as part of a program to expand markets for farm products. Funds were appropriated only to pay for labor for preparing and serving the lunches; the government donated the food supplies. This program originated in 1933 when we were in the midst of vast unemployment The problem was to utilize food surpluses and to get the food to the persons who needed it. This was done through governmental purchase and distribution. In 1940 a school milk program made milk available in many schools; in 1943 the nutritional factor became a requisite for local school lunch sponsors in securing federal funds. The federal program then became a cash indemnity system with the government authorized to reimburse the states for part of the expense of serving a nutritionally adequate lunch. It was in this form that the National School Lunch Act of 1946 made the program permanent. In addition, direct distribution of food to schools has been continued by the U. S. Department of Agriculture.

During 1936-1937 the U.S. Department of Agriculture conducted investigations in sixty-six counties in five broad geographic regions. The results indicated that with respect to seven nutrients--protein, calcium, phosphorus, iron, vitamin A, thiamine and ascorbic acid--fewer than one fifth of the families of this country had food supplies in 1936 that met the recommendations in an optimum diet of the Food and Nutrition Committee of the National Research Council. About one fourth of the rural families were in this category and one fourth of them also fell short of the recommended dietary goals in calcium and/or vitamin A, one half or more with respect to thiamine, riboflavin and/or ascorbic acid.

In Boone County, Indiana, which is above average economically and where farmers raise most of the food they need, a survey made in 1946 of 3,000 pupils from first grade through high school showed that (1) 20 per cent of the children ate no breakfast; (2) a majority of the children ate packed lunches which were usually nutritionally inadequate, and (3) about 15 per cent of the children had the same food at the evening meal as had been served at the noon meal. They had too little fruit, and the meals were not balanced. Food was eaten frequently between meals. In general, consumption of milk was low. The best average in the county by schools was two and one-half cups (a little over 1 pint, 473 cc.) a day to a low of four cups (1 quart, 946 cc.) per week in any form. There was ample food, but not the right kind. A twelve year continous study of 10,000 Pennsylvania school children showed that " 85 per cent failed to exhibit reasonably good nutrition in one or more respects." In Minnesota a seven day dietary survey of 1,080 pupils in rural, town, suburban and city schools showed that 40.2 per cent had poor diets, 32.2 per cent fair diets and only 27.6 per cent good diets. In Georgia, Maryland and Michigan the data were similar.

Dr. W. H. Sebrell, of the U.S. Public Health Service, and chief, Division of Physiology, National Institute of Health, cited to the House Committee on Agriculture many recent studies made throughout the country which revealed that school children were suffering from inadequate diets. Among these were the following:

1. In a study of Texas school children, about 20 per cent of those examined were anemic enough to need medical treatment. This type of anemia was due to insufficient iron.
2. A survey of 200 children in West Virginia showed that 54 per cent were getting poor or bad diets.
3. In an area in Vermont the children's teeth were outstandingly poor; 1 in 4 had spongy gums, probably due to deficiency in ascorbic acid.
4. A dietary survey of more than 1,100 Maryland school children revealed that only 8 per cent had an adequate diet.

A study conducted by the Department of Home Economics of the Florida Agricultural Experiment Station covering the period 1940-1945 started with 186 children from a strictly rural community. Ninety-four of the children ate regularly in the lunch room for four years, and 82 were present for the entire period of five years. The school lunch was prepared under the direction of a dietitian and met optimal standards. The principal result was the shift from a pronounced clinical deficiency to a condition of near sufficiency. Also, the hemoglobin values of both sexes and all ages increased during the school year and decreased during vacation.

So in 1946 when there were no agricultural surpluses and employment was at an all time high the Congress passed the National School Lunch Act. Although partly financed by federal funds, the school lunches are still a community affair. Any group that is interested can cooperate with school officials in initiating and carrying out the program. The sponsor, however, must be a school official and the school must be a public or nonprofit private school of the high school level or under. The following limiting requirements must be met: (1) the program must be operated on a nonprofit basis; (2) lunches must meet the nutritional requirements set up under the act by the Department of Agriculture, and (3) the lunch must be available to all children, regardless of their ability to pay and without discrimination.

The diet pattern for three types of lunches has been set up with the rates of reimbursement dependent on the type of lunch served. The type A, or complete lunch, receives the highest rate of reimbursement at a maximum of 9 cents per lunch. The requirements for this lunch are ½ pint(237cc.) of whole milk as a beverage and the following or their equivalent: (1) 2 ounces (54.7 Gm.) of lean meat, poultry, fish or cheese; (2) three-fourths cup of vegetables or fruit; (3) one or more portions of bread and (4) 2 teaspoons (7.76 Gm.) of butter. The type B lunch, which brings a federal reimbursement of 6 cents per lunch, provides about two thirds as much food as the type A lunch. It may be served if a school has limited lunch room facilities but should be supplemented by food brought from home. The type C lunch, which consists of ½ pint (237 cc.) of whole milk as a beverage rates a reimbursement of 2 cents. The department of Agriculture donates some foods, such as dry milk. Schools participating in the reimbursement program are eligible to receive these foods.

The most controversial part of the National School Lunch Act is the section relating to federal payments to states. These federal funds are apportioned among the states by a formula which takes into consideration the number of schoolage children in a state and the per capita income of the state. The law requires that until 1951 federal funds accepted be matched dollar for dollar from sources within the state. From 1951 to 1955 inclusive the states shall receive funds on the condition that each dollar will be matched by one and one-half dollars. After 1955 payments shall be made on condition that each dollar will be matched by three dollars.

We cannot discontinue federal programs and federal aid in one fell swoop without causing hardships and loss of funds already invested. We must move gradually to take the federal government out of these projects. This law is written so that it will be to the advantage of even the poorest states to have the program wholly supported by the state within the next ten years.

The Act of 1946 has one grave defect: the amount to be spent on the program is left to the discretion of Congress each year through appropriations to the Department of Agriculture. The trouble now is that Congress is not willing to appropriate the funds considered necessary to expand the program. Prior to enactment of the National School Lunch Act of 1946 the greatest number of children participating in the program at any one time was 6,655,458 in the year 1945. For the fiscal year 1946-1947 Congress appropriated $75,000,000. Of this amount, $10,000,000 was earmarked for equipment. During the year the program expanded to a point where additional funds were needed and Congress appropriated an additional $6,000,000, making a total of $81,000,000. The number of children participating at the peak of that year was 7,133,927.

For the fiscal year 1947-1948 Congress appropriated only $65,000,000. The decreased appropriation and increased cost of food has handicapped operation of the program. In 1943, when the federal reimbursement for a type A lunch was set at a maximum of 9 cents, the cost of preparing the meal was 17 cents. In 1946-1947 the average cost was 22.9 cents. Increased costs and decreased appropriations have placed the states' agencies in the position of having to decide whether to reduce the number of children being assisted or to cut further the already low rate of assistance per child.

A rise in price to the paying children is accompanied by a decrease in the number of children participating. In Chicago at the beginning of the 1947 school year it was necessary to raise the price of the type B lunch from 8 to 20 cents; participation dropped from 30,000 children daily to 10,000. The authorities immediately tried to reduce the cost per child and did get it down to 15 cents; the participation then went up to 20,000 daily. They later increased the cost to 18 cents, and the number of children being fed dropped to 18,000.

The President's budget request for the fiscal year of 1948-1949 is for only $65,000,000, which is the same amount as was appropriated for the current fiscal year. Last year the National Cooperative Milk Producers Federation was convinced that $100,000,000 was needed to expand the program and so testified before the Appropriations Committees of Congress. The federation intends to request that amount for the school lunch program for the coming year. Those who believe that this is a worth while program should write to their Congressmen and express the need for more federal funds.

Health Education

JOSEPH W. FICHTER, Master, Ohio State Grange, Columbus: The schools recognized the importance of health education many years ago by including physiology in the course of study. This was at least a beginning in health education. By 1915, many schools had introduced courses in hygiene and sanitation, and home economics classes were receiving suggestions about balanced meals. In 1918 a committee of the National Education Association named health as the first of the seven cardinal objectives of education. Much remains to be done. Cancer is a commoner disease of childhood than it is usually supposed to be. A five year study in Michigan revealed that more persons under 20 years of age died from cancer than from diphtheria, syphilis, measles, poliomyelitis, scarlet fever, typhoid, whooping cough or acute rheumatic fever. Only tuberculosis outranked cancer as a cause of death among the diseases studied. A study conducted in Denver estimated that 15 to 40 school children per thousand reveal definite signs of rheumatic heart disease.

Comparatively few schools have an effective health program. The situation is worse in the rural schools than in the city schools, as a result of lack of funds and in many cases lack of interest. The first step in providing health education for every child consists of efforts by the medical profession, schools, farm organizations and other groups to arouse interest in the possibilities of maintaining good health through eating habits, good sanitary conditions, recreation, play and other means. Second, we should work for the enactment of legislation which will provide local public health units equipped to serve every family. Also, we should urge appropriations for state departments of health and for the U.S. Public Health Service adequate to assure sufficient high type professional personnel needed in an expanding health education program. A basic part of health education is preparation of prospective teachers in teacher-training institutions and inservice training for teachers. A state supervisor of health should be a part of each state department of education. In each school there should be a teacher in charge of health, except in the smaller schools which might be served by a circuit teacher. Each child should receive a complete physical examination before entering school, and at least every two years thereafter. These examinations should be followed promptly by corrective and protective measures. There should be more emphasis on play and recreational activities which reach all pupils and less emphasis on highly competitive interschool athletic contests. Especial attention should be given to mental health.

Community Cooperation

Dr. DEAN F. SMILEY, Bureau of Health Education, American Medical Association, Chicago: We need a cooperative system of health appraisal. This is a job for physicians, parents, teachers, nurses and the entire community. Parents should give a health review to a child before he goes to school in the morning. A child who looks as if he is going to be ill should not be sent to school. Teachers have a continuing service, a screening test. They are expected to carry on the weighing, measuring, vision and hearing tests. The work of the physician in health appraisal varies in different parts of the country. In New York state medical examinations are in the hands of the education department and required every year. In Wisconsin they have a scheme for examinations every three years. In Illinois examinations are given every four years. The American Medical Association's bulletin on periodical health examinations recommends examinations of school children at three year intervals; if reasons for additional examinations develop between examinations, they will be had.

Who should do the examining? In California the members of the medical profession prefer to do the examining and it is done in the schools. The family physicians cooperate with the school physicians in giving the examinations. Another scheme is to set up a school physician and to give him such assistance as he needs with part time physicians hired, if necessary. One variation is to bring in and establish examining teams of physicians and to let each practice his specialty and get the examinations done at one time in the autumn.

There is considerable variation in the scope of the examination. Many health examinations in the schools have been hurried inspections. A child goes by so fast that the physician does not see the boy back of the throat at all. We can go to the other extreme and insist on a pediatric examination lasting forty-five minutes to one hour. We can hardly justify that in our schools at this time.

The joint committee on health problems is recommending a health examination about fifteen to twenty minutes in length. Before the test is given the mother fills out a history chart and the teacher does certain routine screening tests; the mother is present at the examination to give assistance and information. With that sort of scheme about fifteen minutes would be adequate.

How can defects be corrected? In many cases it is a matter of convincing the parents. Topeka, Kan., has a scheme under the prepaid insurance plan. The medical society guarantees through the insurance program, a nonprofit program, that there will be complete medical care to welfare families, and the prepaid insurance program is paid $4 per month per family The procedure simply is automatic and authorities are not particular about applying a means test where the scheme is in operation That plan would have the advantage of a wide cooperative scheme of health appraisal, and the follow-up would give a program of health service that would be quite effective

DISCUSSION

DR. MOENCH, Hillsdale, Mich.:It has been my experience that there could never be a school health program until the teachers and the parents and the health advisory agencies in the communities sit down and discuss problems.

MRS. ASHER YAGUDA, public relations chairman, Women's Auxiliary, Newark, N.J.:Last June we gave a program on health education. We impressed our director of health education so much that he asked us to help in implementing the program of health education in the schools in New Jersey. The program we were asked to implement has four points: 1. Examination. We interpret this to mean we must drop routine examinations, which must be completed in the first three months of the year, but must have individualized examinations with the parent present at the examination. 2. Examinations on admission (preschool), fourth, eighth and twelfth grades, as a minimum. 3. Each county superintendent of schools must have facilities of a psychiatrist at his command. A psychiatrist for which this plan calls will act as consultant. 4. All school teachers and personnel to be arranged for every two years. It became increasingly apparent to us that we had to do a good job on the county level at first. We organized health councils. We consider the county councils as a group which will endure as steering councils of the communities. To carry out the plan perfectly, we must set up within them the type of councils that Dr. Smiley has told about. We have been working some four months on the implementation of these councils, which have been organized in eleven of our twenty-one counties to carry through this four point program.

DR. CHARLES H. LERRIGO, Topeka, Kan.:I have been connected with the tuberculosis associations for some forty years. I want to remind you of the way to get help. To Mr. Fichter I say turn to Dr. Robert Peterson of Columbus, Ohio, and tell him that the rural schools of Ohio do not have proper health education largely because of lack of textbooks and proper teaching. I venture to say that every county in Ohio which is represented here today has a good active tuberculosis health association that will gladly finance the matter of production of authoritative books. To Mrs. Taylor I say that every tuberculosis association she can contact (there is one in every county) is interested in nutrition. They are interested to the extent of supplying professional nutritionists. State boards of health also have nutritionists.

DR. FOUTS, Omaha: I want to ask a question Mrs. Taylor mentioned the funds for school lunches. Those who could not pay were being supplied with lunches without cost. What type of means test is given to decide who can receive lunch without money?

MRS. TAYLOR, Washington, D.C.:I understand it is taken care of by the local authorities. They know the children who are not able to pay their share. It is done quietly so that the children themselves do not know who contribute. There is nothing written into the law. There is no discrimination. The lunch must be available to all children where lunches are served.

MISS MABEL RUGEN, Ann Arbor, Mich.:In Chicago they adjust the lunch to the individual students. The program is carried on at the local level. Where there is a problem of a child being able to pay, the financial assistance comes from various sources and is handled, I believe, largely through the school superintendent's office.

DR. R.W. FOUTS, Omaha:Is there any provision for part pay?

MISS MABEL RUGEN, Ann Arbor, Mich.:I think so. The individual child pays what he is able to pay. One way to put into effect some of the suggestions made here would be to needle the school administrators when you go back home. I believe that a cooperative plan that can be carried on through the local health department, representatives of medical and dental societies, farm organizations and other civic organizations can be one of the greatest influences in getting changes in the schools.

DR. MOENCH, Hillsdale, Mich.:The teachers and superintendent and nurses working with these children know whether they can afford to pay or not. Every effort is made to prevent embarrassment to the parents or the children. Many technics can be worked out so that the children can do a little work around the school. They help to administer the free lunches to the children. We have a responsibility to have persons keep their self respect as far as receiving charity is concerned.

MRS. MARGARET DREISBACH, Washington, D.C.: Federal funds are apportioned to states. The program in the states is administered by state personnel in the department of education. The only restriction or specification that is set up by the federal government in the administration of the program is that the nutritional standard be followed for the lunches.

MR. FRANK PECK, Managing Director, the Farm Foundation, Chicago: I would like to pay my respects to the American Medical Association for its efforts to bring the rural picture before its staff and the general public. We have had plenty of statistics and talk. Now we should decide who does what and when and get action into these programs

The Rural Health Program

DR. JAMES R. MCVAY, Chairman, Council on Medical Service in Rural Areas, American Medical Association, Kansas City, Mo, Presiding: Last year I talked before this group about some of the problems of voluntary prepayment medical plans. I believe that it is by meetings such as these that we will be able to develop a solution to the problems of rural medical help. The Council on Medical Service has been particularly interested in voluntary prepayment medical care plans in their distribution to the rural population. The Council on Medical Service is most happy to coordinate its activities with the activities of this group.

Women's Auxiliary

MRS. GRACE HUTCHISON, Woman's Auxiliary, The National Grange, Xenia, Ohio: In our county each Grange has a home economics committee. We stress nutrition and sponsor nutrition contests each year. We are going to try to have our granges devote programs to health. Many who do not practice health rules are unaware of their existence. To the American Medical Association and the farm groups, we pledge our firm support.

MRS. EUSTACE A. ALLEN, *Woman's Auxiliary, American Medical Association*, Atlanta, Ga.: I represent the Woman's Auxiliary to the American Medical Association We are intensely interested in the health of this nation. One of the major problems of the auxiliary is health. We have contacts with civic groups, schools and other lay groups. They can present talks, motion pictures and debates on health. These are not altogether medical problems, but problems of good housing, sanitation, proper diet, clothing and health education, which must begin in the home. What can be done to help educate the family? Some of the projects that the auxiliary is sponsoring maintain loan funds for medical students. the stipulation being that the recipient on graduation must return to his native state and practice in a rural area for two years. Many states have this project. The membership of the Woman's Auxiliary is over 36,000 and represents seven hundred and twenty-five counties in forty-five states. Members are in an excellent position to take part in any health program inspired by these rural health conferences and to help in any way. As another project we work up public relations programs. There are a great many wives of physicians in rural areas. and they are members of all your groups. Ask them to help you promote a health program. Our facilities are at your disposal.

DR. MCVAY, Kansas City, Mo.: The American Medical Association is proud of its Woman's Auxiliary and the work it is doing. It is an important part of the work of the medical profession.

Hill-Burton Program

DR. VANE M. HOGE, Medical Director, U.S. Public Health Service, Washington, D.C.: The hospital survey and construction act gives special privilege and consideration to rural areas. The problems discussed here are national. One recent development in the administration of the hospital program regards decentralization. This is primarily a local and state program and not a federal program. For that reason the division of hospital facilities has recently decentralized its activities to eight district offices. This will make it easier to obtain information. The district directors are now authorized to answer your questions.

The program has been under way some eighteen months Today we have approved thirty-three state hospital construction plans. A great many more are practically complete, and before the end of this fiscal year we expect to have all the states of the nation included in the program. We had as of yesterday approved one hundred and twenty-four hospital projects. Thirty-three state plans which we have approved entail an annual allotment of over $62,000,000. The total for each year is $75,000,000. Most of the states are now in sight of the operation of the program. The approved projects total somewhat over $13,000,000 in federal funds which, of course, constitute one third of the total. Of immediate interest to this audience is the construction phase of this program.

Our reports, compiled weekly, reveal that a great majority of the hospital projects are in communities of less than 5,000 population in hospital service areas in which there are now no existing acceptable hospital beds. Included in the one hundred and twenty-four projects are health centers, nurses' homes and tuberculosis and mental hospitals. Seventy of the one hundred and twenty - four are general hospitals. Forty-five have somewhat under fifty beds; eighteen have from fifty to seventy-five beds; three have from seventy-five tc one hundred; seven have over one hundred. The average is about fifty beds. From these figures it would appear that the rural areas are receiving a high priority, which Congress intended them to receive

The cost of the hospitals is a subject of much concern. A great many factors enter into the discussion of bed costs. There are variables. From the estimates coming in most costs are ranging between $7,000 and $13,000 per bed. The higher figures usually include extra facilities. Construction costs since 1939 have gone up from 90 to 100 per cent. The law authorized $3,000,000 for survey purposes. That money goes to state agencies and not to individual communities. We have paid out to the states about $800,000 so far. The survey does not end when the state plan is complete. It will be necessary to make modifications and amendments, and surveys are needed for individual community projects. With three exceptions all the states and territories have qualified themselves for monies. A few more have not asked for any funds because they have enough of their own. Another activity to which we have given time has been the training of state personnel.

One worry in the beginning was that this program would be new to the state health department. Our fears have been unfounded. A good type of technical personnel has been attained, and they are going through very well with their work. We have held three orientation or training classes in Washington, D. C., for personnel from the state department of health. Each course runs four months.

The act provides no funds for maintenance and operation of hospitals. It will be difficult for some areas to have an assurance of operating the hospital after it is constructed. In many states this matter has been alleviated somewhat by state appropriations. In eight states appropriations have been authorized for assistance in construction. Each will provide one third of the cost. It has been apparent from the beginning that this present five year program would not go far along the road to meet all the needs. It is clear that the present program in its entirety will fill only 13 per cent of the entire need. Many communities are going to be disappointed. The trends that I have mentioned indicate the necessity for states to get out and raise money to build hospitals.

Pediatric Service

DR. RALPH V. PLATOU, Head, Department of Pediatrics, Tulane University School of Medicine, New Orleans: The equalization of pediatric services among children in rural and urban populations will be difficult but not impossible to attain. A successful approach must have the cooperation of all agencies interested in the welfare of children. The overlapping interests of our educational systems, health departments, social agencies and organized medical groups can at times be so complex as to make long-term planning difficult. A sound program by which the child specialist can function directly in the interests of the rural child must use all facilities possessed by all these groups, must minimize existing frictions and reduplications of effort, must be simple and forceful enough to gain everyone's active interest and must be so effective that it will attract an increasing number of young physicians to participate in the movement. Success will depend almost entirely on the amount of enthusiasm and support generated in each local community.

A small proportion of the total medical care extended to the children of our nation is furnished by child specialists. More than a fourth of our total population is made up of children, more than a third of whom live in isolated semirural and rural counties Of three thousand and five hundred pediatricians in the United States, only four are located in these areas and about three hundred in semirural counties. The most important factors determining distribution of physicians are economic considerations, hospital facilities and educational or cultural advantages for their families. There are not now, and probably never will be, enough child specialists to " go around." Even conscientious relocation would not help much at present. The ratio of child specialists to children, state for state, would obviously still remain the same; in Louisiana, for example, there would still be only one child specialist for every 14,000 children. The major burden of medical care for all segments of the population will continue to fall on the willing shoulders of general practitioners. Less than 5 per cent of all our physicians are to be found in isolated rural counties! Something drastic must be done to attract more physicians to the country: better hospitals, better schools, better highways, better subsidies and better planning for continuing programs of postgraduate medical education. The formation of Rural Health Councils can do much to coordinate the activities of all professional and lay organizations working for the betterment of rural health. Such a program of coordination can work only if current plans for adequate hospital training of prospective general practitioners are expedited and rural practice itself is made more attractive. We should require that at least a part of each young physician's training and experience be gained in rural hospitals.

What can be done now? The most sensible immediate solution to the problem is this: a well qualified child specialist will come from the medical schools directly to rural areas to act as coordinator of all available facilities for improving child health, as a consultant for practicing physicians, health officers and educators, and to interest younger physicians in problems of rural children. Such a consultant will cover a large territory and cannot often be concerned with the problems of individual children; for the most part he will teach, conduct demonstrations and establish policies. In some areas he will have to " start from scratch " to build an effective program. His main concern will be to reduce the well meant but often unnecessary duplications of effort brought about by overlapping interests of many existing agencies. This work should be implemented almost entirely by the medical schools, realizing that success will depend on the cooperation of all existing health agencies. Such a consultant ought to be able to work effectively with the physicians in each community. Through the medium of county medical societies and regional hospital staff meetings he can bring valuable practical interpretations of recent advances; he can improve the quality of some meetings by arranging programs suited to particular regional needs and by employing other authoritative speakers directly from the medical schools in those areas he is serving. He can organize in the medical schools short graduate courses specifically designed to fill the needs of physicians in rural practice. Working with local school authorities, practicing physicians and health officers, he can organize effective courses in all aspects of health education; through these same agencies he can implement better systems for periodic health examinations and routine immunization procedures. Such consultants are already working out into the rural areas of Louisiana and Southern Mississippi from our two medical schools in New Orleans. Eight other medical schools have the same plans. Similar arrangements have been made in obstetrics; closer integration of efforts in these two fields will naturally improve practices in maternal and child health in all areas.

Health Councils

DR. H. B. MULHOLLAND, Member, Committee on Rural Medical Service, American Medical Association, Charlottesville, Va.: Health Councils had their origin from a desire to coordinate the activities of widely divergent groups with one primary object, the betterment of health in this country. Health Councils are apparently active in Alabama, North Carolina, West Virginia, Vermont and Virginia. Plans are well under way for the development of health councils in the country as a whole. I have been associated with the Virginia Council on Health and Medical Care since its beginning in 1945. This Health Council consists of forty or more organizations: farm groups; home economics groups; medical groups, including the Medical Society of Virginia, whose president is automatically a member of the Executive Committee, the Negro Medical Society, Graduate Nurses Association, the two state medical colleges, the Mental Hygiene Society and the state dental society; the Conference of Social Workers, Association of County Government Officials, League of Women Voters, National Foundation for Infantile Paralysis, American National Red Cross, Cancer, Tuberculosis and Society for Crippled Children, State Chamber of Commerce, Ruritan and Rotary Clubs also have memberships. This does not include all the member organizations. In addition, individuals may also have membership.

Its objectives are to strengthen through a united effort a full health program for the state, to serve as a clearing house on health and medical care problems and programs, and to help eliminate overlapping of effort. We have been careful not to interfere with any individual program of the member organizations. The primary purpose of the council is to serve as a forum for discussion of problems of health and medical care. The support for this council comes from voluntary contributions from member organizations and from individual members. We have an executive director. Certain programs have been supported: expansion of local health departments, so that every county might be covered by a department; augmentation of the salaries of persons working in health departments; establishment of a Bureau of Cancer Control in the state department of health; initiation of a program to care for the indigent; expansion of the tuberculosis program, and an increase in the number of rural scholarships for students who are studying medicine. All these are accomplished facts. Now that the Hill-Burton program is in full swing, the council is supporting a bill to ask the legislature for money to construct facilities where they are most needed.

The present program of the Council includes expansion of our services for treating the mentally ill, increased appropriations for cancer control and care of the indigent, establishment of scholarships for those who wish to enter hospitals for nursing training and initiation of an experimental project to explore the field of over-all prepayment insurance. The council realizes that health education is an extremely important subject, and it is supporting all the efforts in this direction. It recently had a program which had been broadcast daily throughout the state. A number of local health councils are being started throughout the state, and they will be affiliated with the statewide health council. We believe that the leadership for the initiation of these local units should come from the county medical society, but that the group within such an organization should include everyone concerned with health in its broadest aspects One cannot overemphasize the importance of local cooperative effort in the study and support of the problems of medical care. I urge that all of you go home with the idea of cooperating in the development of local health councils.

DISCUSSION

MR. LLOYD HALVORSON, National Grange, Washington, D. C.: Group practice is one way to get the specialists into rural areas. I don't want to minimize the importance of the general practitioner. Possibly he, too, should be part of a group practice team. I want to call attention to legislation in Wisconsin last year. Cooperative groups worked with the members of the medical profession to get legislation satisfactory to both, enabling consumers to organize their own health plans. I hope that physicians in all states will follow that policy, working with rural groups and establishing broad legislation which will permit consumers to form their own health policy.

MR. JERRY VOORHIS, Secretary, Cooperative Health Federation of America, Chicago: The Cooperative Health Federation of America exists to promote voluntary prepayment health plans. We believe that only as groups voluntarily come together to share on a prepayment basis the need and risks of medical care can it be made possible for rural areas to have the facilities and professional personnel they require. Our organization would be opposed to the interference of laymen with medical procedure. Our organization is dedicated to the proposition that voluntary prepayment plans will over all time be the best answer to these problems. They make certain that persons have a choice. What has happened in Wisconsin is a course of action that could be well copied elsewhere. It is the best single type of legislation that has been passed.

Outline of the Iowa Plan.—Health education forums are being carried on by the interprofessional association and the department of health. The state medical society, dental society, nurses association, pharmaceutic and veterinary medicine groups are cooperating with the state department of health and holding forums. We submit a list of fifty topics. The group of a community organization selects six to be discussed, three in the afternoon and three in the evening forum. We find that with the interprofessional groups getting out into the communities a greater interest in health councils is developing. That is the specific technic being used in Iowa.

DR. R. W. FOUTS, Omaha: In Nebraska we are soon meeting to divide the funds for hospitals. I would like to ask Dr. Hoge whether, in the event that a state is not able to utilize all the funds allocated by the federal government, the unused portion will carry over to the next year or will go back into the general fund.

DR. V. M. HOGE, Washington, D. C.: The allotment is made for a year to a state with an approved plan. You will have an allotment for this fiscal year and it will be good through the following fiscal year. There are two years in which to allocate one year's allotment.

DR. R. W. FOUTS, Omaha: If by the first of June we have not been able to allot the full amount extended to Nebraska for this year, we can go into next year and we would still have the same amount for this year as for next year ?

DR. V. M. HOGE, Washington, D. C.: Your plan was approved and allocated this year. If no grants were made this year, next year you would have double the amount.

DR. ROBERT L. MACCORNACK, Whitehall, Wis.: I have charge of a small hospital in a rural group. About two years ago I made a survey of accidents in our community and found we had three hundred and thirty-three accidents in our small town. Five were fatal. In this group of accidents we were surprised to find that a great percentage occurred in children. When we consider rural health we should give thought to the accident prevention campaign.

DR. A. W. BROWNING, Elloree, S. C.: The good roads and automobiles create a tendency for persons to go to cities to see physicians and use the local physicians for night calls only. We must impress on the young men that if they will go to rural sections they will find that they can lead good, abundant lives.

SUMMARY

RANSOM E. ALDRICH, Chairman, Medical Care Committee, American Farm Bureau Federation, Jackson, Miss.: I want to say to the lady from the Woman's Auxiliary that there are a million farm women in farm women's organizations. There is an opportunity to expand your services. We will be happy to cooperate.

I would like to see the budgets raised for maintenance. If we want hospitals, we can provide maintenance without federal aid. I come from a county that has an assessment of less than $3,000,000. We floated a bond issue and sold bonds at a premium. We provide a clinic and cooperative agreement with the area hospital and maintenance funds at the same time. I want to say to Dr. Mulholland that I am heartily in accord with his idea of a council. I hope that we can keep it as a forum, to promote an active program in areas where we can reach an agreement.

DR. CLIFFORD G. GRULEE, Secretary, American Academy of Pediatrics, Evanston, Ill.: Why are we saying so much about poor rural health? We have suddenly been startled by the fact that it is healthier to live in a city than in the country. That is contrary to all established ideas. The city doesn't deserve any credit. When things get so bad they can't get worse, we do something about it. If the people in the country are not aroused to the needs of the children in that community, we won't get very far. All rural health has not been so bad. Oregon is a rural state, but until the past few years it had the lowest infant death rates in the country. This rural health problem is a local problem. It is one the local community will have to solve. What about the Mexicans? There are much higher death rates in states where the Mexicans live than in any other states in the union. We must have funds from a central group to take care of them.

LUNCHEON MEETING

DR. F. S. CROCKETT, Lafayette, Ind., Presiding

DR. A. C. SUDAN, Denver: I don't have to tell you how deeply I am honored by the American Medical Association's first annual award to a general practitioner. This award is actually a recognition of the splendid efforts of all general practitioners. It reminds people that life in the best nation of the world gets the best medical care from a family physician and not from socialized medicine. Problems of rural health have occupied almost all of my professional life. We know that the health of America can be improved, but the only proper approach to the problems of rural health is by free people working together in a community spirit without any compulsion from the government. In the Rocky Mountain region community interest in better rural health is increasing. Many small towns are going ahead with new hospitals in spite of scarcity of building materials, building them as community projects instead of waiting for a handout from Uncle Sam. We know that whoever pays the fiddler has the right to call the tune. If a dollar is sent first into Washington it is trimmed and trimmed and comes back to the community as a smaller piece of change. We must work more closely with the school boards, the teachers, the parent-teachers organizations, and the health councils to bring about the day when every school child will receive sound basic training in personal and health happiness.

DR. EDWARD L. BORTZ, President, American Medical Association, Philadelphia: This conference is significant because of the fact that so many farm organizations represented here are participating with the American Academy of Pediatrics and the American Medical Association in an all-out search for methods to improve the health of our citizens who are in charge of the nation's agriculture. One cannot stress too strongly the fact that a healthy citizenry is essential to our country's prosperity and future security. Organized medicine is aware of the importance of child health. One of the major items of its national health program is: "Every child should have proper attention, including scientific nutrition, immunization and other services included in infant welfare." The various councils of the American Medical Association are focusing their activities on numerous aspects of child health and welfare. One of the strongest committees of our Association is that on Rural Medical Service. Data of importance have been collected, and with these facts to guide our Association, plans for improving health in the farm districts are under way. Where the approach from the national level is expedient our Association has gone into action; local problems oft-times can best be worked out at the community level.

The creation of health centers and diagnostic clinics and the improvement of hospital facilities are on the way. Frequent conferences between community health leaders and those who mold public opinion, in association with medical authorities, are being held. Health classes in the schools and the encouragement of health talks on the radio and through other channels of communication represent another activity of the American Medical Association.

A sound health program should begin in childhood and continue throughout the life of all persons. In developing a wholesome program for our citizens of tomorrow the American physician has never been more competent. With his excellent medical education and understanding of health problems he is well equipped to assume leadership. When organizations like those representing our farm groups unite with organized medicine in a unified program for improving the health services of rural districts, there is much hope for a more vigorous nation. Let me assure you that the American Medical Association is working diligently in the interests of a healthier people.

Losers, Finders, Keepers

DR. EDWARD E. ELLIOTT, President Emeritus of Purdue University, Washington, D.C.: Nearly fifty years ago I found myself a starving chemist so I went to teaching. I was superintendent of schools. I know that education, as we understand that term, is fruitless unless we are dealing with healthy human beings. For the past two years I have been studying the profession called pharmacy. I have been studying the character and personalities of the 100,000 legally licensed pharmacists. In 1947 the physicians of this country delivered to these pharmacists 350,000,000 prescriptions. In the official catalogues there are today in excess of 25,000 different forms of medicinal preparations on the market. I have been interested in discovering one significant fact. The annual sale of pill or packaged medicine without prescriptions reaches the tremendous sum of $500,000,000 a year. We call this self medication. We still believe in magic. Physicians come in contact with it every day. A man of misspent life appears before you. He wants a pill that will produce instantaneous recovery. I am reading from a clipping from the American Museum of Natural History. Ten million Americans buy rabbits' feet each year. The human mind does not develop as rapidly as the things it seeks to control. As I look on the medical problem I do not see as clearly as some of you apparently do the distinction between rural medical service and medical service in the city. I agree with George Bernard Shaw who said this is a foolish thing that a sound body is the production of a sound mind. The goal of such crusades as that represented by this conference cannot avoid becoming concentrated on men's minds as a necessary prerequisite for the salvation of their bodies. As I sat through this morning's meeting I kept asking myself, are they reaching a decision that we can afford these things if we will? The question is not one that belongs even under the valiant leadership of the American Medical Association. It belongs to the whole of our leadership to create a sense of individual responsibility, the individual responsibility of the parent for the child, the individual responsibility of a community for its own welfare, and above all the individual responsibility of each person for his own welfare. The great need is not more physicians but fewer patients. The price that we are going to pay is not in terms of skilful medical service altogether, nor is it in terms of money; the price we are going to pay is the effort required to recapture our own sense of self responsibility.

Washington Letter

(From a Special Correspondent)

June 2, 1948.

Membership in World Health Organization Indicated

Legislation authorizing membership of the nation in the World Health Organization was voted 6 to 3 by the House Rules Committee, where it had been held up for eleven months. Indications were that the measure would be given early approval by Congress. The bill was revised to limit to $1,920,000 a year the contribution of the federal government to the world agency. The bill was passed by the Senate almost a year ago and the House Foreign Affairs Committee cleared it through but the Rules Committee tabled it. The new organization meets in Geneva in June, and the State Department advocated passage so that this country can participate. House Speaker Joseph W. Martin Jr. endorsed the bill, along with the House Steering Committee, but delay was encountered again in the Rules Committee which requires a unanimous vote to remove a bill from tabling. Representative Walter H. Judd, Republican of Minnesota, dissolved the impasse by submitting a slightly revised bill. A new provision requires the President to appoint, for Senate confirmation, a practicing physician or surgeon with at least ten years' experience to represent this country on the executive board of the World Health Organization. The bill also states that there must be nothing in the constitution of the world health group which would commit the United States to enact any specific legislation.

Medal of Merit Awarded to Scientists

Defense Secretary Forrestal announced that the Medal of Merit had been awarded to sixty-five scientists and engineers of the wartime Office of Scientific Research and Development. The President's Certificate of Merit was awarded to three hundred and eighty-seven other persons, and the War and Navy Department Certificate of Appreciation to seven hundred and eighty-two others. At a ceremony in the Pentagon Building, Dr. Vannever Bush, director of the office during the war and presently chairman of the Research and Development Board and president of the Carnegie Institution in Washington, presented the Merit Medals to the following: Drs. Leason Heberling Adams, John Swalm Burlew and Richard Brooke Roberts, all of Carnegie Institution; Edward F. Knipling, Bureau of Entomology, Agriculture Department; Roger Sherman Warner Jr. and Carroll Louis Wilson of the United States Atomic Energy Commission and Alan Tower Waterman, Office of Naval Research.

Registry of All Known Cancer Cases

Health officials of the District of Columbia announce that a register will be kept of all known cases of cancer, similar to the record now kept of every known case of tuberculosis. Officials are studying the system of cancer control now in use in Hartford, Conn. Insurance figures reveal an improved general health condition in the national capital.

Plans for Army Hospital at Forest Glen Postponed

Possible unification of hospital facilities of the Army and Navy has resulted in plans being dropped for the proposed thousand bed Army general hospital at Forest Glen, Md., according to Representative Bates, Republican of Massachusetts. Abandonment of the Forest Glen plans was recommended by the Army Surgeon General. The House passed by voice vote a bill totaling $194,631,440 for installations at Army and Air Force posts around the world.

Medical Legislation

STATE LEGISLATION

Mississippi

Bills Enacted.—H.282 was approved April 13, 1948. It authorizes the incorporation of organizations for medical and surgical purposes or for establishing, maintaining and operating clinical, pathologic, medical or surgical research laboratories or the like. Such corporations shall not be required to make publication of their charter, shall issue no shares of stock, shall divide no dividends or profits among their members, shall make expulsion the only remedy for nonpayment of dues, shall vest in each member the right to one vote in the election of all officers, shall make the loss of membership, by death or otherwise, the termination of all interest of such members in the corporate assets, and there shall be no individual liabilities against the members for corporate debts, but the entire corporate property shall be liable for the claims of creditors. H. 290 was approved April 13. It authorizes the establishment of a scholarship program for the advanced study of nursing which consists of forty scholarships of the value of not more than $3,000 each. Students accepting assistance from these scholarships must agree to spend a period of time working as nurses in Mississippi equal to the number of years during which they accepted the benefits of the scholarships. H. 291 was approved April 14. It authorizes the establishment of a school of nursing at the University of Mississippi and inaugurates a scholarship program in connection therewith. H. 310 was approved April 14, 1949. It makes an appropriation of $130,000 for the purpose of defraying the expense of educating and treating children afflicted with cerebral palsy, such sum to be expended under the supervision of the state board of education by the Mississippi crippled children's service. H. 312 was approved April 13. It amends the Mississippi code relating to the regulating of registered nurses by clarifying the powers and duties of the board of nurses' examiners. H. 532 was approved April 13, 1948. It amends the law relating to the Mississippi Commission on Hospital Care by, among other things, authorizing it to lay out a plan for building and equipping schools of nursing to be located in strategic points in the state for the promotion of the advancement of nursing education. H. 533 was approved April 12. It amends the hospital construction act by providing authorization for operating and equipping health centers or health departments in the various municipalities of the state. H. 687 was approved April 13. It enacts a hospital licensing law and, in conjunction therewith, provides for the appointment of an advisory hospital council to consult and advise with the licensing agency and to assist in the development of rules, regulations and standards to be required of hospitals seeking licensure. No such rules, regulations or standards shall be adopted or enforced which would have the effect of denying a license to a hospital or other institution required to be licensed hereunder, solely by reason of the school or system of practice employed or permitted to be employed therein. S. 446 was approved April 13, 1949. It requires all persons licensed to practice pharmacy to renew their licenses annually.

GOVERNMENT SERVICES

NAVY

NEW REGULAR OFFICERS

Lieut. Comdr. William M. Crafft and Lieut. John H. Stover, both of the Naval Reserve, have returned to active duty to accept appointments in the Regular Navy Medical Corps.

The following members of the graduating class of the medical school indicated have accepted appointments as lieutenants (jg) in the Regular Navy Medical Corps: Merrill A. Bender of Ohio (Harvard); John H. Bowen of California (College of Medical Evangelists); Charles R. Campbell of California (Tulane University School of Medicine); Harold J. Crecraft of Pennsylvania (University of Maryland School of Medicine); Joseph H. Early Jr. of Virginia (George Washington University School of Medicine); William T. Gyles of Oklahoma (University of Oklahoma School of Medicine); Jerome L. Heard of Louisiana (Tulane University School of Medicine); John B. Jacob of Oklahoma (University of Oklahoma School of Medicine); Cunningham R. MacCordy of Louisiana (Tulane University School of Medicine); Norman P. Morin of Maine (McGill University School of Medicine), and Forrest W. Olson of South Dakota (University of Oklahoma School of Medicine).

NAVAL CAREER IN RESEARCH

The Bureau of Medicine and Surgery has added the field of research to the list of specialties for which medical officers may qualify and thus be assured of spending a major part of their Naval career in research. While the qualifications required for this specialty are not inflexible, it is desirable to have a Ph.D. degree in a basic science. However, the application of any officer of the Naval Medical Department having an interest in research as a career will be considered, and if such training is indicated he will be started on a tour of duty at one of the Naval Medical Research Institutions, followed later by a short tour of sea duty to provide an over-all picture of the Navy's needs. Training in civilian research laboratories will be offered also. Applications are desired from physicians and other scientists now in the Naval Reserve and also from qualified civilians interested in a career of naval medical research.

VETERANS ADMINISTRATION

VOLUNTARY SERVICE NATIONAL ADVISORY COMMITTEE

Representatives of thirty-five national organizations, comprising the Veterans Administration Voluntary Service National Advisory Committee, met at the central office in Washington, D. C., May 27. Under the voluntary service plan, each organization assists in the program under its own identity and cooperates with other member groups of the local committee in a general program for hospitalized veterans. The program has developed in all veterans' hospitals to the point where a voluntary service committee is coordinating the work of all voluntary groups. The meeting was addressed by Carl R. Gray Jr., Administrator of Veterans Affairs; Dr. Paul B. Magnuson, Chief Medical Director, and Mr. F. R. Kerr, Assistant Administrator for Special Services and chairman of the national committee.

TELETYPE NETWORKS IN VETERANS' HOSPITALS

To speed up service, the Veterans Administration announces that teletype networks permitting almost instantaneous communication between branch offices and hospitals have been installed. A regional office attempting to locate a hospital bed for a veteran requiring immediate hospitalization can teletype simultaneously to all hospitals within the area; thus the veteran can be assigned to the nearest hospital having a vacant bed. The new system using leased teletype lines at flat rental rates replaces commercial telegraph and long distance telephone services whenever possible. The leased line systems result in saving to the government by reducing the number of long distance calls and telegrams. Before this system was installed the average telecommunication cost in branch office 2, encompassing the state of New York, averaged $5,000 a month and now averages $3,000 a month, although the volume of messages has increased from 2,500 to 7,000.

CONFERENCE ON REVISION OF LISTS OF DISEASES

Eugene L. Hamilton, chief, medical statistics division, Office of the Surgeon General, recently returned from Paris, France, where he was a member of the United States Delegation to the Conference for the Sixth Decennial Revision of the International Lists of Diseases and Causes of Death. The conference, which was convoked by the government of France, included representatives from some twenty-eight countries. The United States delegation included Dr. Halbert L. Dunn, of the National Office of Vital Statistics, chairman; Dr. George Baehr, president of the New York Academy of Medicine; Dr. Joseph Berkson, chief statistician, Mayo Clinic; Dr. E. F. Daily, director, division of health services, Children's Bureau; Dr. P. M. Densen, chief, division of medical research statistics, Veterans Administration; Dr. H. F. Dorn, chairman, statistical section, National Cancer Institute; Dr. W. Thurber Fales, director, statistical section, Baltimore City Health Department; Mr. E. L. Hamilton, chief, medical statistics division, Office of the Surgeon General, U. S. Army; Dr. I. M. Moriyama, chief, mortality analysis section, National Office of Vital Statistics; Dr. Edward S. Rogers, dean, School of Public Health, University of California, and Capt. Robert L. Ware, chief, division of medical statistics, Bureau of Medicine and Surgery, U. S. Navy. It is expected that responsibility for the periodic revisions of these international lists will now be assumed by the World Health Organization.

CONTRACTS FOR HOSPITALS

A contract has been awarded for the construction of a two hundred bed Veterans Administration hospital at Saginaw, Mich., costing $4,000,000. Construction is expected to begin within the next thirty days.

RETIRED HOSPITAL MANAGER HONORED

Dr. Hans Hansen was guest of honor at a testimonial dinner at Geneva, N. Y., on the occasion of his retiring from the Veterans Administration after twenty-eight years of service, the last thirteen of which were as manager of the veterans' hospital at Canandaigua. About two hundred and fifty members of the staff and other friends attended. The honored guest was presented with a set of luggage as a token of esteem from his associates. Dr. Hansen is a graduate of Creighton University School of Medicine, Omaha, and is a veteran of World War I. During his period at the hospital the bed capacity has been increased from about 700 to nearly 2,000. Dr. Nils B. Horsloff, who will succeed Dr. Hansen as manager, is a graduate of Columbia University Medical School, New York; interned at St. Elizabeths Hospital, Washington, D. C.; studied at the Wagner Juaregg Clinic in Vienna, Austria; engaged in private practice, was instructor in psychiatry at Columbia, attending psychiatrist at the New York Psychiatric Institute and chief of the psychiatric clinic at Lenox Hill Hospital for several years. During the recent war he served in the medical corps in North Africa, Sicily, Italy and the Persian Gulf commands.

PUBLIC HEALTH SERVICE

DEADLINES FOR APPLICATIONS FOR RESEARCH GRANTS

The National Institute of Health, Bethesda, Md., has set the following deadlines for the receipt of applications for U. S. Public Health Service grants in support of medical research: June 15 for applications to be reviewed at the September meeting of the National Advisory Cancer Council; July 15 for applications to be reviewed at the October meeting of the National Advisory Mental Health Council and August 1 for applications to be reviewed at the October meeting of the National Advisory Health Council.

DR. WISHIK APPOINTED TO CHILDREN'S BUREAU

Dr. Samuel M. Wishik, head of the division of physically handicapped children of the New York City Health Department, has been appointed to the U. S. Children's Bureau to direct the planning work for the program of grants in aid to the states for maternal and child health and for crippled children's services. He will be particularly concerned with developing standards for and improvements in these health services, thus helping the field staff and the state health departments. The Children's Bureau is authorized by the Social Security Act to grant $18,500,000 a year to the states for these programs.

Dr. Wishik was formerly director of the Hawaii Health Department services for maternal and child health, and for crippled children. During the war he was commissioned in the U. S. Public Health Service. He is certified by the American Board of Pediatrics. In his new position Dr. Wishik succeeds Dr. Abram L. Van Horn, who resigned to direct the Kate Macy Ladd Fund in Newark, N. J., which was established to provide medical care for convalescents.

AWARDS AND COMMENDATIONS

Dr. Robert L. Cherry

The United States of America Typhus Commission Medal was recently awarded to Dr. Robert L. Cherry, surgeon (R), U. S. Public Health Service, now deputy administrator of the Red Cross in Alexandria, Va. The citation read as follows: He rendered exceptionally meritorious service in the control of the epidemic of typhus fever at Naples, Italy, during the period Dec. 20, 1943 to Feb. 20, 1944. As chief of a section for case finding and epidemiologic investigation, he carried heavy responsibility. Dr. Cherry's excellent work contributed materially to the successful checking of this epidemic, thus protecting both civilians and American troops. The decoration was awarded in a ceremony last June in Bogota, Colombia, while Dr. Cherry was with the office of the Institute of Inter-American Affairs.

DR. DEARING APPOINTED DEPUTY SURGEON GENERAL

The U.S. Public Health Service has announced the appointment, effective May 17, of Dr. W. Palmer Dearing as Deputy Surgeon General to succeed Dr. James A. Crabtree. Before entering the Public Health Service in 1934 Dr. Dearing taught epidemiology at Harvard University School of Public Health and preventive medicine at Harvard Medical School, where he graduated with honor in 1931. During the recent war he was assistant chief medical officer and later chief medical officer of the Office of Civilian Defense; afterward he did personnel work in the health division of UNRRA, serving in North Africa and Europe. Recently he has been chief of the division of commissioned officers in the public health service. Dr. Crabtree on leaving his previous position will serve on detail as head of the medical unit of the National Security Resources Board, working on mobilization planning in the medical field.

AID CANCER TEACHING PROGRAMS

The U. S. Public Health Service announced the award of grants totaling $435,706 for cancer teaching programs in medical and dental schools as part of a $2,000,000 program to improve the teaching of cancer. These grants bring the total already made to $1,389,573 distributed to sixty medical schools and seventeen dental schools, the individual sums ranging from $5,000 to $25,000.

PERSONALS

Dr. Paul A. Lindquist, senior surgeon (R), has been assigned to the State Department for duty with the American Mission for Aid to Greece. He will conduct special training on trachoma, leprosy and venereal disease control and will serve also as liaison officer with the Greek War Relief and Near East Foundation.

Dr. Leslie W. Knott, surgeon, has been appointed deputy director of the public health division of the mission for aid to Greece, to succeed Vernon G. MacKenzie, who has returned to the United States to take charge of the Stream Pollution Laboratory at Cincinnati.

HOSPITAL NEWS

President Truman and the Federal Board of Hospitalization have approved the acquiring of a 15 acre site in Boston, within a mile and a half of Harvard Medical School, for a thousand bed veterans' hospital. Previous sites authorized for this hospital were abandoned because the Veterans Administration could not obtain title.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Stanley Osborn Day.—In recognition of more than twenty-five years of faithful public service, the Connecticut Public Health Association celebrated Stanley H. Osborn Day May 12. The scientific program held at Yale University School of Medicine emphasized trends in public health practices. Panel discussions were held on the health of the school child, infant diarrhea in hospitals and the future of the voluntary nursing agency health councils. In round table discussions the general hospital as a community health agency and chronic diseases were discussed. Speakers at the reception and banquet were: Charles E.A. Winslow, New Haven, Conn., Reginald M. Atwater, New York, Erval R. Coffey, New York, and Stanley H. Osborn, Hartford.

Dr. Osborn, a graduate of Tufts College Medical School, Boston, 1914, became a district health officer in the Massachusetts State Department of Public Health in 1916. He came to Connecticut in 1920 as deputy commissioner of health and has been state commissioner of health since 1922. He has also been a lecturer in public health at Yale since 1924.

FLORIDA

Rabid Foxes.—A fight against rabid foxes has been started by the state board of health, Florida Fresh Water and Fish Commission and the State Livestock Sanitary Board. S.M. Canup of the U.S. Fish and Wildlife Service is in Florida to supervise the work. The situation has become so acute that rabid foxes on several occasions have come into towns and attacked dogs, cattle and in some instances human beings.

ILLINOIS

Terminate Emergency Maternity and Infant Care Program.--Federal funds will not be available for maternity care received after May 31 under the emergency maternity and infant care program for wives and babies of enlisted servicemen, the state department of public health has announced. This is an additional step in the termination of the war emergency program established by Congress to provide maternity and infant care for the wives and babies of enlisted men. The program was placed on a liquidation basis by Congress as of June 30 last year. Since November 1942, when the program started in Illinois, about 62,000 wives have received maternity care. Also, medical and hospital care has been provided for about 13,000 infants. This program has been administered by the division of maternal and child health of the state department of public health.

Chicago

Hospital News.--Mount Sinai Hospital opened its new two story sixty bed addition late in May. Twenty per cent of the beds in the new wing have been allocated for service to patients unable to pay.

Fraternity Lecture.--Dr. R. Scott Stevenson, London, England, will deliver the William W. Root Lecture at the annual dinner of the Alpha Omega Alpha at the Palmer House, Chicago, June 24, on "The Birth of Laryngology."

Alvarez to Give Irish Lecture.—The second annual Henry E. Irish Memorial Lecture was delivered by Dr. Walter C. Alvarez, Rochester, Minn., on June 9 at 1 p.m. in room 221, University of Illinois College of Medicine, on "The Vanishing Art of Diagnosing with One's Eyes and Ears." The lecture is sponsored by Eta Chapter of Alpha Kappa Kappa in honor of the late Dr. Henry E. Irish, a former member of the faculty of the University of Illinois.

Lectures for Prospective Fathers.—Chicago Lying-In Hospital and Dispensary of the University of Chicago is presenting three evening classes, June 1, 8 and 15, for expectant fathers in the Chicago area in the Dora DeLee Hall at the hospital. The first lecture, devoted to psychology of pregnancy and labor, was presented by Dr. William J. Dieckmann, chief of staff. Miss Catherine Sheckler, assistant professor of nursing education, delivered the June 8 dual lecture on family life and the new baby. A pediatrician from the Bobs Roberts Memorial Hospital for Children and Miss Maxine Green, dietitian at Chicago Lying-In Hospital, will conclude the lectures with the topics, Baby's First Year and Making the Formula. Classes are free of charge. Prospective fathers are invited to register by writing the nursing department of Chicago Lying-In Hospital, 5841 Maryland Avenue, Chicago 37.

IOWA

Appointments and Promotions.—Dr. Adolph L. Sahs has been appointed head of the department of neurology at the University of Iowa College of Medicine, Iowa City, where he has been professor and acting head since the retirement of Dr. Clarence Van Epps in 1946. A native Iowan, Dr. Sahs received his M.D. degree at the college of medicine in 1931 and joined the staff of the neurology department in 1933 as an instructor, becoming a full professor of neurology in 1946. He held a Rockefeller Foundation Fellowship in neurology in 1938-1939. Others appointed are: Dr. Frederick H. Hesser, assistant neurologist and instructor in neurology at Duke University School of Medicine, Durham, N.C., as assistant professor of neurology; Dr. Raymond R. Rembolt, Lincoln, Neb., as director of the State Services for Crippled Children and medical director of the School for Severely Handicapped Children; Dr. Wendell P. Stampfli, Denver, as assistant professor of radiology; Dr. Otis S. Lee Jr., research fellow, as assistant professor of ophthalmology. These appointments are effective July 1.

LOUISIANA

Society News.--The newly organized New Orleans Academy of Internal Medicine has elected Dr. Thomas P. Findley Jr. president and Dr. Samuel B. Nadler secretary-treasurer.

Personal.--At a recent meeting of the Louisiana State University Medical Alumni Association in Monroe, Dr. Thomas A. Richardson, Minden, was elected president, and Dr. Donald B. Williams, Lafayette, secretary-treasurer.

MASSACHUSETTS

Personal.—Brig. Gen. James Stevens Simmons, Army, retired, dean of the Harvard School of Public Health, on April 16 was elected president of the Association of Schools of Public Health at the annual meeting of the association held at the Connaught Laboratories, University of Toronto, Canada. On April 19 he delivered the James D. Bruce memorial lecture in preventive medicine at the annual convocation of the American College of Physicians in San Francisco, where he also was awarded the James D. Bruce Memorial Medal for Achievement in Preventive Medicine.

MICHIGAN

Hospital Survey.—The Michigan Office of Hospital Survey and Construction reports that the state plan for hospital facilities was approved by the Michigan Advisory Hospital Council at its April 8 meeting. When approved by the Surgeon General, U.S.Public Health Service, the plan makes Michigan eligible for $2,171,000 a year for five years to assist local communities in developing hospital facilities. Michigan, which now has 14,040 suitable beds in general hospitals, needs 27,776 beds according to U.S.Public Health Service standards.

MINNESOTA

Carman Lecture.—The annual Carman Lecture of the Minnesota Radiological Society was given by Dr. Paul C. Hodges, professor of radiology, University of Chicago School of Medicine, June 7, on "The Role of X-Ray Pelvimetry in Obstetrics." Dr. Hodges also spoke at the society banquet at the Minneapolis Club at 6:30 p.m. on "Notes on Three Current Developments in Diagnostic Radiology."

MISSOURI

State Medical Elections.--At the annual meeting of the Missouri State Medical Association March 14-17, Dr. Robert Mueller, St. Louis, was installed as president and Dr. W. Wallis Smith, Springfield, president-elect. Dr. Perry W. Jennings, Canton, was elected secretary and Dr. William A. Bloom, Fayette, treasurer.

New Preventive Medicine Professor.—Dr. Robert E. Shank, New York, has been appointed professor of preventive medicine and head of the department of *preventive medicine and public health at the Washington* University School of Medicine, St. Louis, effective July 1. Dr. Shank is a graduate of the school of medicine, 1939, and is at present with the William H. Park Laboratories in New York.

MONTANA

Annual State Medical Meeting.—The Montana State Medical Association will hold its annual session at the Northern Hotel, Billings, June 16-19, under the presidency of Dr. Louis W. Allard. Out of state speakers, all from Denver, will be: Bernard B. Longwell, Ph.D., endocrine interrelationships, and Drs. E. Stewart Taylor, treatment of gynecologic cancer; Clarke H. Barnacle, psychiatric implications of the climacteric and senescence; Henry Swan, age of choice for surgery in children, and Robert W. Gordon, treatment of nephritis, Two panel luncheons have been arranged for Thursday, one on Developments in Thoracic Surgery and one on Advances in Endocrinology. Friday's panel discussions at luncheon will take up Advances in Psychiatry and Obstetric Anesthesia. A buffet supper and dancing will be held Thursday. At the banquet Friday, eighteen physicians who have been practicing fifty years or more will be honored as charter members of Montana's Fifty Year Club. The Woman's Auxiliary will meet in conjunction with the state meeting.

NEW JERSEY

Poliomyelitis Institute.—The New Jersey Poliomyelitis Institute will be held at the Academy of Medicine in Newark on June 9, and at the Walt Whitman Hotel, Camden, June 10. The morning program will be made up of the present concepts of the nature of poliomyelitis and its methods of spread, the treatment of early poliomyelitis and the management of patients with bulbar and respiratory difficulties. On the afternoon program, physical medicine and rehabilitation, prevention of deformities and roles of the Crippled Children Commission, State Department of Health and Rehabilitation Commission will be discussed.

NEW YORK

Personal.- Dr. Clinton P. McCord, Albany, has been appointed consultant in psychosomatic medicine to the New York State Department of Health.

Community Honors Health Officer.—More than 250 Irondequoit residents, school, town and health officials recently arranged a celebration in honor of Dr. Willis W. Bradstreet, the town health officer since 1918 and school physician for the Durand-Eastman School for twenty-five years. His diligence in establishing diphtheria and smallpox inoculation clinics in Irondequoit has resulted in more than 90 per cent protection of the resident children.

Dr. Beebe Heads Department of Medicine.--Dr. Richard T. Beebe has been appointed professor of medicine and director of the department of medicine at Albany Medical College effective July 1, succeeding Dr. L. Whittington Gorham, director since 1937. Dr. Beebe, a graduate of Johns Hopkins University School of Medicine, Baltimore, 1928, has been dispensary physician in charge of the outpatient department at the Albany Hospital, where he will become physician in chief.

Committee to Aid Handicapped Persons.—The Monroe County Medical Society has formed a permanent committee to deal with employment of physically handicapped persons in Rochester. The group, under the chairmanship of Dr. G. Kirby Collier, will distribute information to employers and employees on compensation and other state and federal laws governing the employment of handicapped persons; hold periodic employer institutes where the value of employing handicapped persons in different types of jobs will be stressed; disseminate information to handicapped persons explaining advantages open to them, through recognized agencies, to train and obtain employment. The committee will be known as the Rochester Committee for the Employment of the Handicapped.

New York City

Merge Obstetric and Gynecologic Services.—Beth Israel Hospital, Stuyvesant Park East and 16th Street, announces the merger of the obstetric and gynecologic services and the appointment of Dr. Henry C. Falk, New York, as director of the service.

Large Bequest for Research.—New York University was bequeathed more than $400,000 from the estate of the wife of the late Dr. Joseph Talbot Maclean. The terms stipulate that income from the bequest shall be applied to carrying on medical research. Dr. Maclean was a graduate in 1876 of Bellevue Hospital Medical College. After years of practice in Ohio and New York, Dr. Maclean died in 1920. Mrs. Maclean's death occurred July 10, 1947.

Columbia Given Eye Institute Library. - Columbia University Library has received as a gift the bibliography section of the library of the former Dartmouth Eye Institute. It was made possible through the efforts of Professor Clifford L. Treleaven, associate professor of optometry at Columbia, and Robert E. Bannon, formerly on the staff of the Dartmouth Eye Institute and now a member of the faculty of optometry at Columbia. The Dartmouth Eye Institute, formerly affiliated with the Dartmouth Medical School, closed in June 1947. Another gift is the private collection of Herman Gould, Brooklyn, retired, which includes a large number of books on vision and related subjects. The Dartmouth bibliography includes a 50,000 card index file of papers and several hundred reprints of articles related to investigations in binocular vision. There are also three hundred translations of important German publications relating to binocular vision, space perception, refraction, visual acuity and allied subjects.

NORTH CAROLINA

Academy of General Practice.—The North Carolina branch of the American Academy of General Practice was organized in Greensboro on February 22, with ninety physicians present. Dr. John R. Bender, Winston-Salem, was elected chairman and Dr. Roscoe D. McMillan, Red Springs, secretary and treasurer.

Cancer Clinic Opens.--A public cancer detection clinic in James Walker Memorial Hospital, sponsored by the New Hanover County Medical Society, opened April 27 in Wilmington. Dr. Ivan M. Proctor, director, state health board's cancer control division, and Mrs. George M. Marshall, commander, state division of the American Cancer Society, were the opening day speakers.

OHIO

Narcotic Violation.--The Bureau of Narcotics, Washington, D. C., reports that Dr. Charles R. Colburn, Osborn, pleaded guilty at Dayton to an indictment charging violation of the federal narcotic law and on January 28 was placed on probation for a period of two years.

State Medical Election.—At the annual meeting of the Ohio State Medical Association in Cincinnati, Dr. Arthur Brindley, Toledo, was installed as president and Dr. Carl A. Lincke, Carrollton, was named president-elect. The next annual meeting is to be held in Columbus the week of April 19, 1949.

Meeting at Zanesville.—At a meeting of the Muskingum County Academy of Medicine in Zanesville, May 13, Dr. Fred W. Rankin, Lexington, Ky., spoke on trends in the surgical treatment of cancers of the lower portion of the intestinal tract; Dr. Louis E. Prickman, Rochester, Minn., on diagnosis and treatment of asthma, and Dr. William D. Seybold, Rochester, Minn., on carcinoma of the lung and of the esophagus.

PENNSYLVANIA

Society News.—The Study Club of the Reading Eye, Ear, Nose and Throat Society was addressed May 5 by Dr. Ferris F. Ketcham, Reading, on "Pathologic Explanation of Common Ophthalmoscopic Findings."

Dietary Instruction for Diabetics.—The Philadelphia County Medical Society's diabetic committee, in collaboration with the Philadelphia Dietetic Association, is presenting four classes for the dietary instruction of diabetic persons at the Society Building, May 27, June 3, 10 and 17, from 7:30 to 9 p.m. Patients attending must have been enrolled by their physicians and must bring notes from their physicians indicating the particular diet recommended. General dietary instruction is given during the first half hour of the class and is followed by individual instruction. There is no registration fee.

VERMONT

State Medical Meeting.—The Vermont State Medical Society with the cooperation of the University of Vermont College of Medicine met May 27 at Burlington, where the following subjects were discussed: atomic energy, its application to medical practice; plastic surgery of the eyelids; diagnosis and treatment of ear infections; recognition and treatment of acute poliomyelitis, and surgical treatment of peptic ulcer.

WISCONSIN

Course in Poliomyelitis.—The University of Wisconsin Medical School, Madison, will present a course in poliomyelitis, June 28–July 3, covering the practical aspects of diagnosis and treatment. Each participating physician will have an opportunity to learn the technics of muscle testing, the application of hot packs, muscle reeducation and respirator care along with the epidemiologic aspects of the disease. The course has been arranged in cooperation with the Wisconsin county chapters of the National Foundation for Infantile Paralysis, and the Wisconsin Hospital Association. Details may be obtained from Dr. Llewellyn R. Cole, coordinator of graduate medical education, Medical School, 418 North Randall Avenue, Madison 6.

WEST VIRGINIA

State Medical Election.—At the recent meeting of the West Virginia State Medical Association, Dr. Thomas F. E. Bess, Keyser, was installed as president and Dr. Thomas G. Reed, Charleston, was made president-elect. Dr. T. Maxfield Barber, Charleston, was reelected treasurer for the twenty-second consecutive term. Dr. Walter E. Vest, Huntington, was reelected delegate to the American Medical Association for a two year term. A new section on neurology was created and will take over the functions of the neurology association organized in Huntington last September. It is the sixth section to be organized within the association.

GENERAL

University of Pittsburgh Alumni Luncheon.—The University of Pittsburgh Medical Alumni will hold a reunion luncheon in the South Ballroom of the Stevens Hotel, Chicago, June 23 at noon.

Electroencephalographers Meeting.—The American Electroencephalographic Society will hold its second annual meeting June 12–14 at the Claridge Hotel, Atlantic City, N.J. The presidential address by Dr. Herbert H. Jasper, Montreal, Canada, will be given at the dinner Saturday evening. The program includes a symposium on the physiologic basis of epileptic discharge.

Association for Study of Internal Secretions.—This association will hold its annual meeting June 18-19 at the Palmer House, Chicago, under the presidency of Dr. Cyril N. H. Long, New Haven, Conn. Ninety-one papers will be presented. The annual dinner will be June 18 at 7:30, when awards will be presented and the president will address the group.

Judd Awards.--At the opening of the Sloan-Kettering Institute for cancer research, April 16, Judd Awards were made to Professor Alexander Haddow, director, Chester Beatty Research Institute, Royal (Free) Cancer Hospital, London, for research on carcinogenesis, and to Dr. Eric Boyland, Ph.D., professor of biochemistry, University of London, for studies on the metabolism of carcinogens.

Medical Alumni Meeting.—The University of Pennsylvania Medical Alumni will hold a dinner at the convention of the American Medical Association, Chicago, Wednesday, June 23, at the Lake Shore Club, 850 Lake Shore Drive. On arrival in Chicago alumni should contact Miss Frances R. Houston, executive secretary of the Medical Alumni Society, at the University of Pennsylvania registration booth.

Meeting of Tuberculosis Physicians.—The American Academy of Tuberculosis Physicians will hold its annual meeting at the Palmer House, Chicago, June 19, under the presidency of Col. George F. Aycock, Nashville, Tenn. Among the subjects to be discussed are streptomycin-resistant tubercle bacilli, tuberculoma and meningitis, use of oleothorax for the unexpandable lung, and thiamine and methionine. The luncheon speaker will be Dr. William F. Petersen, Chicago.

Johns Hopkins Alumni Dinner.—The Alumni Association of Johns Hopkins University is sponsoring a dinner Thursday evening, June 24, during the American Medical Association meeting, to honor Drs. Helen B. Taussig and Alfred Blalock, who recently received the Passano Foundation Award for their development of the surgical treatment of " blue babies." The dinner will be in the Hotel Stevens, Chicago, at 6 p.m. and will be terminated to conform with the other meetings scheduled for that evening.

Conference of State Associations Officers.—The annual Conference of Presidents and Other Officers of State Medical Associations will meet at the Sheraton Hotel, Chicago, June 20, 12:30-5 p.m., under the presidency of Dr. L. Howard Schriver, Cincinnati. The group will be addressed by:

Joseph H. Howard, Bridgeport, Conn., Despotism by Consent of the Governed.
Paul R. Hawley, Washington, D.C., The Blue Shield-Blue Cross Program.
John W. Cline, San Francisco, Why a State Medical Association?

International Congress.—The International Federation of Sport-Medicine has announced its general assembly will be held June 29 in Prague, Czechoslovakia. The seventh International Medical Congress of Physical Education will be held July 1-5 in connection with the XI Sokol Festival, Prague. At the conclusion of the congress, trips through Czechoslovakia will be organized for the members. The application fee of 400 koruns allows for the railway reduction for the participation at the Sokol festival and for the Congress publications. Applications from abroad should be sent to Professor MUDr. Jiri Kral, Praha II., Vladislovova 15, Czechoslovakia.

Train Tuberculosis Fellows in Denver.—Four fellows, appointed by the Interim Commission of the World Health Organization from various countries, on July 1 will begin six months' free instruction in methods of tuberculosis prevention, control and treatment at the National Jewish Hospital, Denver. Beginning Jan. 1, 1949 the World Health Organization will send annually twelve fellows who will receive instruction at this hospital, the University of Colorado School of Medicine, Fitzsimons General Hospital and other Denver institutions. Traveling expenses fill be financed by the organization. Living expenses will be contributed by the International Foundation for Medical Research and Education.

Chest Physicians Annual Meeting.—The American College of Chest Physicians will meet at the Congress Hotel, Chicago, June 17-20 under the presidency of Major General Shelley U. Marietta (Retired), Washington, D. C. The guest speakers include:

Francisco Torres, Cordoba, Argentina, Pulmonary Resection in Tuberculosis.
Gumersindo Sayago, Cordoba, Argentina; Jose I. Baldo, Caracas, Venezuela; Arlindo de Assis, Rio de Janeiro, and Ismael Cosio Villegas, México D.F., México, experience with BCG vaccination in their respective countries.
Andre Soulas, Paris, France, Study of Bronchial Stenosis in Bronchopulmonary Tuberculosis.

Clinics and round table luncheons limited to twenty to thirty persons each have been scheduled.

Medical Milk Commissions.—The American Association of Medical Milk Commissions, Inc., will hold its annual convention at Avalon Hotel, Waukesha, Wis., June 18-21. Physicians and others interested in improving standards for production of milk are invited. On Saturday afternoon a seminar on nutrition and certified milk has been planned, the participants being Dr. Tom D. Spies, Chicago, Dr. Christian E. Segard, Madison, and Paul H. Phillips, Ph.D., Madison. Visits to certified milk farms in Waukesha County will begin at 10 a.m. Sunday. At the banquet Sunday at 7 p.m. Dr. John P. O'Neil, chairman, Committee on Nutrition, Chicago Medical Society, will speak on "What Does the Physician Want in Prescribing Certified Milk?"

International Poliomyelitis Conference.—Twenty international medical scientific authorities will present papers on poliomyelitis at the first International Poliomyelitis Conference at the Waldorf-Astoria Hotel, New York, July 12-17. Following are the speakers:

Albert B. Sabin, Cincinnati, Epidemiologic Patterns of Poliomyelitis in Different Parts of the World.

Irvine McQuarrie, Minneapolis, Evolution of Signs and Symptoms.

Herbert J. Seddon, Oxford, England, Economic Aspects of Management of Poliomyelitis.

David Bodian, Baltimore, Pathologic Anatomy.

Fritz Buchthal, Copenhagen, Denmark, Pathologic Physiology.

John A. Anderson, Salt Lake City, Diagnosis and Treatment.

Elexious T. Bell, Minneapolis, Progressive Pathology.

Arthur L. Watkins, Boston, Progressive Disabilities.

CORRECTION

Alcohol - Dextrose and Dextrose - Vitamin Solutions - The report on " Alcohol-Dextrose and Dextrose-Vitamin Solutions for Intravenous Infusion Not acceptable for N.N.R." which appeared under Council on Pharmacy and Chemistry in THE JOURNAL, May 29, pages 462-463, should be corrected to omit the last two paragraphs of the report as it appeared on page 463.

Marriages

LLOYD H. GOAD, Gary, Ind., to Miss Lois Elaine Otto in Sioux City, Iowa, January 4.

JOHN T. MORRIS, Birmingham, Ala., to Dr. SYLVIA J. BURBANK of Pleasantville, Iowa, January 1.

JOHN F. DIXON Jr., Garden City, N.Y., to Miss Ruth Hoerber of Ridgewood, recently.

NIGEL ARTHUR BUXTON to Dr. Elmira Mary Richli, both of Surat, Bombay Presidency, India, March 23.

EDWARD F. LEWISON to Miss Betty S. Fleischmann, both of Baltimore, March 21.

ARTHUR ATKINS SWEETSER Jr., Scranton, Pa., to Miss Jeanette Susanna Buczko of Mount Carmel January 31.

JOEL W. SALON to Miss Marilyn Green, both of Cleveland, April 11.

Deaths

Warren Coleman ⊕ Augusta, Ga.; born in Augusta, Ga., in 1869; University of the City of New York Medical Department, New York, 1891; professor emeritus of clinical medicine at the New York University College of Medicine; served as professor of clinical medicine at the University of Georgia School of Medicine; formerly professor of clinical medicine and applied pharmacology at Cornell University Medical College in New York; member of the Medical Society of the State of New York, Association of Military Surgeons of the United States, Association of American Physicians, American Association for the Advancement of Science, American Gastro-Enterological Association, American Genetic Association and others; fellow of the American College of Physicians; consulting physician to the Lenox Hill and Bellevue hospitals in New York; specialist certified by the American Board of Internal Medicine; died February 13, aged 79.

Joseph A. O'Hara ⊕ New Orleans; born in New Orleans Jan. 23, 1869; Medical Department of Tulane University of Louisiana, New Orleans, 1900; past president and executive officer of the state board of health of Louisiana; formerly professor of preventive medicine and public health, Louisiana State University School of Medicine; past president of the Louisiana Society for Mental Hygiene, Louisiana State Medical Society and Louisiana State Tuberculosis Commission; member of the Southern Medical Association, Southern Psychiatric Association and American Psychiatric Association; coroner of Orleans Parish from 1904 to 1925; served on the local draft board during World War I; for many years on the staff of De Paul Sanitarium; died at Hotel Dieu February 25, aged 79, of congestive heart disease and arteriosclerosis.

Thomas Raymond Healy ⊕ Boston; born March 13, 1879; Dartmouth Medical School, Hanover, N.H., 1899; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., American Roentgen Ray Society and the American College of Radiology; past president of the New England Roentgen Ray Society; served during World Wars I and II; formerly associated with the U. S. Public Health Service; affiliated with Amesbury (Mass.) Hospital, Anna Jaques Hospital, Newburyport, Benjamin Stickney Cable Memorial Hospital, Ipswich, and St. Elizabeth's Hospital; died February 25, aged 68.

Hawley Seager Sanford ⊕ Detroit; born in Milwaukee, Jan. 24, 1909; Harvard Medical School Boston, 1933; interned at the George F. Geisinger Memorial Hospital in Danville, Pa.; formerly a fellow in surgery at the Mayo Foundation in Rochester, Minn.; certified by the National Board of Medical Examiners; member of the Association for Research in Nervous and Mental Disease and of the Central Neuropsychiatric Association; a major in the Army Air Force during World War II; neuropsychiatrist on the staff of Henry Ford Hospital; died February 24; aged 39, of coronary sclerosis.

Walter Clifton Deakyne ⊕ Smyrna, Del.; born in Smyrna Del., Dec. 31, 1891; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1919; past president of the Medical Society of Delaware and of the Kent County Medical Society; served during World War I; served as examining physician for the New Castle County Selective Service Board 2 during World War II; on the staff of the Kent General Hospital in Dover; died February 11, aged 56, of coronary thrombosis.

William Sisson Gardner ⊕ Baltimore; College of Physicians and Surgeons, Baltimore, 1885; an Affiliate Fellow of the American Medical Association; served as treasurer and president of the Medical and Chirurgical Faculty of Maryland; fellow of the American College of Surgeons; professor emeritus of gynecology at the University of Maryland School of Medicine; for many years affiliated with the Mercy and University hospitals; died February 18, aged 86.

Augustus A. Babione ⊕ Luckey, Ohio; University of Maryland School of Medicine, Baltimore, 1903; died in Flower Hospital, Toledo, February 13, aged 75, of virus pneumonia.

Eugene D. Bergeron, Kankakee, Ill.; Chicago Medical College, 1881; died in St. Mary's Hospital February 11, aged 88, of coronary heart disease and cerebral hemorrhage.

William Farmer Briney, Chicago; Bennett Medical College, Chicago, 1897; died February 14, aged 78, of cardiovascular renal disease.

James A. Brown, Portsmouth, Va.; Leonard Medical School, Raleigh, 1903; died February 5, aged 70.

Mary Brown, Drexel Hill, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; died February 5, aged 86.

Frank N. Carrier, Santa Rita, N.Mex.; Jefferson Medical College of Philadelphia, 1893; fellow of the American College of Surgeons; died in a local hospital February 5, aged 75, of adenocarcinoma of the prostate.

Fred Clifford Cave, Oxford, Kan.; Barnes Medical College, St. Louis, 1903; member of the American Medical Association; served during World War I; died in Veterans Administration Hospital, Hines, Ill., Dec. 12, 1947, aged 71, of carcinoma of the bladder.

Leonidas William Cobun, Morgantown, W. Va.; Baltimore Medical College, 1898; member of the American Medical Association; past president of the Monongalia County Medical Society; died February 20, aged 78, of cerebral hemorrhage.

Arthur R. Collins, Watauga Valley, Tenn.; Tennessee Medical College, Knoxville, 1902; died in St. Elizabeth Hospital, Elizabethtown, February 19, aged 72.

John J. Conway, Warren, R.I.; Georgetown University School of Medicine, Washington, D. C., 1901; member of the American Medical Association; served as school physician, police surgeon and coroner; formerly chairman of the school committee and for a time superintendent of the local schools; died February 11, aged 70.

George A. Davis, De land, Fla.; Atlanta Medical College, 1890; member of the American Medical Association; for many years city and county health officer, and physician for the Florida East Coast and Atlantic Coast Line railways; died at the De Land Memorial Hospital February 20, aged 89.

Herman Clyde Duke ⊕ Richwood, Ohio; Eclectic Medical Institute, Cincinnati, 1898; for many years a member of the school board; president of the board of trustees of the Richwood Public Library, of which he had been one of the organizers; died February 7, aged 72, of angina pectoris.

Warner Leaming Eddy ⊕ Milan, Ill.; Rush Medical College, Chicago, 1892; past president of the Rock Island County Medical Society; served as mayor, member of the village council and board of health and president and member of the public school board; past president of the staff of St. Anthony's Hospital, where he died February 9, aged 78, of coronary occlusion.

Arthur Thomas Fagaly ⊕ Lawrenceburg, Ind.; Miami Medical College, Cincinnati, 1893; served during World War I; died February 11, aged 77, of myocardial degeneration.

Liberty Eaton Fellows ⊕ Newton, Iowa; University of Michigan Medical School, Ann Arbor, 1918; member of the American Medical Association; affiliated with the Mary Frances Skiff Memorial Hospital; died February 17, aged 55, of coronary thrombosis.

Edward L. W. Ferry, Millers Tavern, Va.; Medical College of Virginia, Richmond, 1900; member of the American Medical Association; died in the Johnston-Willis Hospital, Richmond, February 17, aged 74, of pulmonary thrombosis.

James H. Fiser, Malinta, Ohio; Toledo Medical College, 1894; member of the American Medical Association; affiliated with the S.M. Heller Memorial Hospital in Napoleon; died February 18, aged 84, of cerebral hemorrhage.

Cyrus Fisher, Central City, Iowa; College of Physicians and Surgeons, Keokuk, 1880; died January 20, aged 93, of heart disease.

Howard Bishop Garner ⊕ Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; fellow of the American College of Physicians; member of the Association of Military Surgeons of the United States; in 1905 member of House of Delegates of the American Medical Association; died February 13, aged 80.

James Shackelford Gay, Ashland, Ala.; Birmingham Medical College, 1905; member of the American Medical Association; died February 3, aged 69.

William Walden Gibbs ⊕ Chicago; Indiana University School of Medicine, Indianapolis, 1917; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; for many years affiliated with Provident Hospital, where he died February 15, aged 57.

Bruce Bentley Giffen, San Diego, Calif.; Ohio Medical University, Columbus, 1906; assistant superintendent of San Diego County Hospital, where he died February 9, aged 68.

Robert Rose Gillespy, New York; Tulane University of Louisiana School of Medicine, New Orleans, 1922; member of the American Medical Association and of the Medical Association of the State of Alabama; served during World Wars I and II; member of the medical board of the New York Life Insurance Company; died in New York Hospital February 17, aged 49, following a pneumonectomy.

Ernst Goldmann, Carlock, Ill.; Schlesische-Friedrich-Wilhelms-Universitat Medizinische Fakultat, Breslau, Prussia, 1923; interned at St. Mary's Hospital in Saginaw, Mich.; died February 18, aged 49, of heart disease.

Anna M. Gove ⊕ Greensboro, N.C.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1892; for many years college physician to the Woman's College of the University of North Carolina, where the college infirmary bears her name; died January 28, aged 80.

Henry James Graham, Mishawaka, Ind.; Detroit College of Medicine, 1900; fellow of the American College of Surgeons; past president of the St.Joseph County Medical Society; affiliated with St.Joseph Hospital; died February 6, aged 72, of coronary thrombosis.

William Perry Griffin, Carlsbad, N. Mex.; Marion-Sims College of Medicine, St. Louis, 1890; died February 13.

Thomas C. Guthrie, Smithville, Ark.; College of Physicians and Surgeons, Little Rock, 1908; member of the American Medical Association; past president of the Lawrence County Medical Society; died February 11, aged 67, of coronary occlusion.

Stanton Heck, Salem, Ohio; Medical College of Ohio, Cincinnati, 1889; formerly vice president of the American Roentgen Ray Society; for many years affiliated with the Salem City Hospital; died February 18, aged 85.

Nathan Just Helfgott, Washington, D. C.; Maryland Medical College, Baltimore, 1912; formerly practiced in Baltimore, where he was on the staffs of Johns Hopkins and Sinai hospitals; on the staff of the Doctors Hospital; died February 20, aged 62, of bronchiectasis and cardiovascular renal disease.

Ralph David Herlinger ⊕ Warren, Ohio; Johns Hopkins University School of Medicine, Baltimore, 1919; fellow of the American College of Surgeons; past president of the Trumbull County Medical Society; served during World War I; affiliated with the Trumbull Memorial Hospital, where he died February 2, aged 55, of complications following an appendectomy.

Henry Hofmann ⊕ Chicago; Northwestern University Medical School, Chicago, 1910; member and past president of the staff of St. Bernard's Hospital; died February 14, aged 62, of cerebral hemorrhage.

Charles Frederic Inlow ⊕ Shelbyville, Ind.; Rush Medical College, Chicago, 1922; served during World War I; formerly secretary of the city board of health; one of the founders of the Inlow Clinic; died in the University Hospital, Ann Arbor, Mich., February 14, aged 53, of hypertension.

Rutherford Bouchard Irones, San Diego, Calif.; Medical Department of the University of California, San Francisco, 1900; formerly mayor; served overseas during World War I; died in the Veterans Administration Center, Los Angeles, February 13, aged 70.

Guy S. Kirby, Marion, N. C.; University College of Medicine, Richmond, 1897; member of the American Medical Association; for many years county physician and surgeon for the Southern Railroad; affiliated with the Marion General Hospital; member and for many years chairman of the board of the State Hospital, Morganton; died in the Norburn Hospital, Asheville, February 15, aged 73.

Charles E. Lukens ⊕ Albuquerque, N. Mex.; St. Louis College of Physicians and Surgeons, 1898; served as superintendent of the Childrens Home and Hospital; died February 14, aged 78, of Paget's disease.

Frank Petrie Mabee, Detroit; Detroit College of Medicine and Surgery; 1919; member of the American Medical Association; fellow of the American College of Surgeons; affiliated with the Alexander Blain Hospital, Woman's Hospital and Grace Hospital, where he died February 11, aged 67, of hypertension.

Ethel Glen McPherson ⊕ Dearborn, Mich.; Indiana University School of Medicine, Indianapolis, 1923; died January 28, aged 51, of coronary thrombosis.

Samuel Thomas Millard, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1906; member of the American Medical Association; served during World War I; on the staffs of Stormont, St. Francis and Christ's hospitals; died February 5, aged 71, of heart disease.

Herbert Strong Nichols ⊕ Portland, Ore.; Hahnemann Medical College and Hospital of Philadelphia, 1895; formerly assistant clinical professor of surgery at the University of Oregon Medical School; member of the North Pacific Surgical Association; fellow of the American College of Surgeons; affiliated with St. Vincent's Hospital and the Good Samaritan Hospital, where he died February 17, aged 79, of cerebral thrombosis.

Robert Tate Nowlin ⊕ Memphis, Tenn.; Memphis Hospital Medical College, 1913; member of the staff of St. Joseph Hospital, where he died February 28, aged 68.

Harry Otten ⊕ Springfield, Ill.; Rush Medical College, Chicago, 1912; formerly vice president of the Illinois State Medical Society; past president and vice president of the Sangamon County Medical Society; fellow of the American College of Surgeons; served as a trustee of the Springfield Medical Library Association; affiliated with St. John's Hospital and the Memorial Hospital, where he died February 18, aged 65, of coronary disease and fracture of the pelvis as the result of a fall on the ice.

Patrick Henry Owens ⊕ Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1912; deputy coroner and formerly county coroner; served during World War I; affiliated with St. Mary's, St. Margaret's and St. Joseph's hospitals; died February 11, aged 64, of coronary occlusion.

Moses D. Pass, Broadwater, Neb.; Cleveland Medical College, Homeopathic, 1896; Kentucky University Medical Department, Louisville, 1899; died in Kearney, February 17, aged 86.

Otto Pfaff ⊕ Oneida, N.Y.; University of the City of New York Medical Department, New York, 1888; past president of the Fifth District Branch of the Medical Society of the State of New York; served as mayor of Oneida, city health officer, president of the water board, county coroner and postmaster; an officer during World War I; for many years surgeon for the New York Central Railroad; died in the City Hospital February 19, aged 84, of cerebral accident.

George Lawrence Pike, Gladwyne, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; affiliated with Gladwyne Colony; died February 17, aged 71, of cerebral thrombosis.

Albert Porter, Cleveland Heights, Ohio; Cleveland Homeopathic Medical College, 1899; died February 14, aged 81, of arteriosclerotic heart disease and diabetes mellitus.

Francis Joseph Ready, Washington, D. C.; Georgetown University School of Medicine, Washington, 1913; member of the American Medical Association; formerly associate professor of clinical medicine at his alma mater; served during World War I; died in the U.S. Naval Hospital, Bethesda, Md.; February 19, aged 62.

Sidney D. Redmond, Jackson, Miss.; Illinois Medical College, Chicago, 1897; also an attorney; died in the Baptist Hospital February 11, aged 76, of paralytic ileus.

Philander Chase Riley ⊕ Lieutenant Colonel, U. S. Army, retired, Fayetteville, N. C.; Columbian University Medical Department, Washington, D.C., 1899; served during World War I; entered the medical corps of the U. S. Army as a major on Sept. 14, 1920; promoted to the rank of lieutenant colonel on Aug. 8, 1937; retired Feb. 28, 1939; returned to active duty on Feb. 18, 1941, serving until Jan. 5, 1944; died February 14, aged 72.

Leon Jerome Robinson ⊕ Palmer, Mass.; Boston University School of Medicine, 1934; interned at the Boston City Hospital; certified by the National Board of Medical Examiners; specialist certified by American Board of Psychiatry and Neurology, Inc.; clinical director of research in epilepsy at the Monson State Hospital; died in the Springfield (Mass.) Hospital February 1, aged 41, of cerebral hemorrhage.

Emma L. Sabin Sherman, Los Angeles; New York Medical College and Hospital for Women, Homeopathic, New York, 1901; died February 13, aged 93.

Ernest Frederick Sickenberger, Woodridge, N.J.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1895; also a graduate in pharmacy; died in Hackensack (N.J.) Hospital February 10, aged 88, of peptic ulcer.

Frank Farrow Simpson, Honolulu, Hawaii; University of Pennsylvania Department of Medicine, Philaphia, 1893; fellow and formerly member of the board of regents of the American College of Surgeons; served during World War I; died February 10, aged 80, of complications following pneumonia.

Philip Sheridan Steelman, Linwood, N.J.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; died in Shore Memorial Hospital, Somers Point, January 13, aged 80, of arteriosclerosis, arthritis and intestinal obstruction.

Myron Scott Stringer, Florence, Ala.; Emory University School of Medicine, Atlanta, 1923; at one time a member of the faculty of his alma mater; died February 13, aged 46, of heart disease.

William Van Zanten, Sheboygan, Wis.; Milwaukee Medical College, 1902; member of the American Medical Association; formerly county coroner; died in St. Nicholas Hospital February 16, aged 78.

Thomas Dupree Vassar, Lakeland, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; member of the American Medical Association; served on the state board of medical examiners; died February 12, aged 60.

James Oliver Wallace ⊕ Pittsburgh; University of Pennsylvania Department of Medicine, Philadelphia, 1906; formerly on the faculty of the University of Pittsburgh School of Medicine; specialist certified by the American Board of Orthopaedic Surgery, Inc.; member of the American Orthopaedic Association; fellow of the American College of Surgeons; on the staffs of Mercy, Children's and Suburban General hospitals; died February 7, aged 71, of coronary occlusion.

Henry V. Walter, Rothsville, Pa.; Jefferson Medical College of Philadelphia, 1904; member of the American Medical Association; past president of the Lancaster County Medical Society; served on the staff of St. Joseph's Hospital in Lancaster; died January 28, aged 69, of coronary thrombosis.

James Blaine Walton, Denver; University of Colorado School of Medicine, Denver, 1919; member of the American Medical Association; died in St. Luke's Hospital February 6, aged 63, of cerebral hemorrhage.

Charles Edgar Welch ⊕ Nelsonville, Ohio; Hahnemann Medical College and Hospital, Chicago, 1896; served during World War I; past president of Athens County Medical Society; president of the First National Bank; died February 18, aged 76, of coronary occlusion.

Herman Joseph Whitehead, Union, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; died in St. Joseph's Sanatorium, Dubuque, February 10, aged 86, of acute cardiac dilatation and arteriosclerosis.

Lee Adrian Whitney ⊕ Rochester, N.Y.; University of Buffalo School of Medicine, 1901; affiliated with the Craig Colony, Sonyea, and St. Mary's, Genesee, Rochester State, Monroe County and Park Avenue hospitals; died February 14, aged 74.

Neri Barndt Williams ⊕ Perkasie, Pa.; Jefferson Medical College of Philadelphia, 1892; also a graduate in pharmacy; died February 4, aged 84, of intestinal obstruction.

Jacob B. Young, Somerset, N.Y.; University of Buffalo School of Medicine, 1900; died January 2, aged 85, of diabetes mellitus and gastric ulcer.

Regulations for the National Health Service

Though no attempt at agreement between the government and the British Medical Association has been made, the former continues to publish regulations which come into force on July 5. These include details which will be required of dentists and doctors accepting service, and particulars of payment and the method by which the public can select their practitioners. They must choose a practitioner from any local list and present him with a medical card. Physicians for children under 16 years will be chosen by their *mothers or, in their absence, by their fathers*, or, in the absence of both, by guardians. For persons incapable by reason of old age, sickness or infirmity, physicians will be chosen by relatives or others having charge of them. Patients will have the right to change their doctors and to have the temporary services of others while moving from place to place or while on holiday. On the other hand, a physician can have a patient removed from his list at any time by giving seven days' notice. But the medical practitioners of each area will be collectively responsible for all service patients under a general allocation scheme.

No doctor practicing alone may have more than 4,000 public patients on his list. In the case of two or more practitioners in partnership, the maximum number of any one partner must be 5,000, but the average for all the partners must not exceed 4,000. Where permanent assistants are employed the number of patients may be increased to an extent not exceeding 2,400 in respect to each assistant. The practitioner's duty to the patient includes "all proper and necessary treatment" but not services involving the application of special skill or experience of a degree or kind which general practitioners as a class cannot reasonably be expected to possess. If such treatment is available as part of the hospital and specialist services, the patient must be informed of the fact, and, if he desires to avail himself of it, the practitioner must take the necessary steps to enable him to receive such treatment. For maternity services the executive councils must keep separate lists of practitioners having obstetric experience, from which a woman may select one if her own doctor is not on it.

With regard to remuneration, a fixed annual payment of $1,200 is to be made to the practitioner, provided he has the minimum number of patients, a capitation payment and payments in respect to temporary residents, for emergency treatment of a person not on his list, in respect to mileage and in cases where the services of a second practitioner are required for administration of an anesthetic. In addition there are to be inducement payments in areas sparsely populated or for any other reason unattractive to practitioners. Also, payments will be made for the training of assistants. Superficially the scheme appears to be well devised to meet every contingency. But, apart from the objections previously given, there is the great snag of flooding doctors' offices with hypochondriacs when all medical treatment is free, leaving the overworked practitioner insufficient time for those really ill.

The Independence Fund of the British Medical Association

The Special Representative Meeting of the British Medical Association decided to establish an Independence Fund to provide financial aid to practitioners who may suffer hardship in the event of the continuation beyond July 5 of the conflict between the medical profession and the government and to provide, through local Independence Committees throughout the country, an organization for maintaining the unity of the profession in its determination not to accept service under the National Health Service Acts until such amendments have been made as will preserve the freedom of the profession. The National Insurance Defence Trust, already established, has deposited with the fund an initial contribution of $1,600,000. The trustees of the fund are appealing to individual physicians to give what they can to make the fund effective. They suggest that there are few practitioners in established practice who cannot afford to give $400 as a first contribution. In their appeal the trustees say: "The danger to the independence of our profession is a measure of the need for generous giving. We appeal to you to give all you can afford to conserve the freedom which neither we nor the public can afford to lose."

International Congress of Industrial Medicine

The ninth International Congress of Industrial Medicine will be held in London Sept. 13-17. The first congress was held in 1906 and the last, ten years ago, the long interval being due to the war. There will be six sections dealing with the various aspects of industrial health, social, environmental, nursing, clinical, practical and special. Rehabilitation will be dealt with separately. Among the topics to be discussed are: young persons in industry; the determination of dusts in air; administration and training; dermatology, burns; industrial medicine in the tropics, and the training of industrial medical officers. Arrangements have been made to visit rehabilition centers, clinics and hospitals. Those who want further information should communicate with the Organizing Secretary, Room 501, Garden Court Wing, B.M.A. House, Tavistock Square, London, W.C. 1.

Streptomycin for Trachoma

Focosi and Scalfi of the university in Sassari reported to the Association of Experimental Biology the results of their efforts to cure trachoma with streptomycin alone or combined with sulfonamide compounds.

The streptomycin was applied in the form of a lotion for the eyes, each drop containing about 1,000 gammas (1 mg.) of the substance.

In 2 cases of papillary trachoma subconjunctival injections of a streptomycin solution in addition to the instillations were given (into the conjunctival fornix and in the folds of the passage). The speakers concluded that streptomycin has a therapeutic effect on the trachomatous nodule, but it may not become manifest before thirty days of continuous treatment. The combined use of streptomycin and sulfonamide compounds did not demonstrate any particular therapeutic efficiency. In cases of florid trachoma the streptomycin had little or no effect. The trachomatous pannus was benefited by the streptomycin, but the effect of the streptomycin was in general not superior to that of the sulfonamide compounds.

The Municipal Medical Association

The Italian Municipal Medical Association held its national congress in Montecatini Terme. Problems for discussion included the municipal physician, pensions, relationship with the Supreme Reciprocity Board and the project of the Public Health League. Concerning a public health career, the congress expressed its vote that the profession should be freed from actual dependence on the community and should be regionalized or provincialized. Concerning the pensions and considering the devaluation of the lira, the request was confirmed to adapt the salaries of these public health men to the actual costs of living. Professor Lucente of Rome also recommended a scheme of reform for the pension funds.

The relationship with the Reciprocity Board, which just now presents the most burning problem for the profession, the subject of a report by Dr. De Vita, was discussed vigorously without reaching a decision. It was decided that an appropriate commission should study the new requests of the members of the medical profession. The next congress will be held in Naples.

Allergy and Appendicitis

At a meeting of the Italian Society of Experimental Biology at Sassari, Dr. Giuseppe D'Aste reported his research on allergy in the pathogenesis of appendicitis. The results of this research seem to confirm the suspicion that in certain forms of appendicitis the allergic-hyperergic mechanism of some alimentary substances may play an important part in the pathologic and clinical picture of appendicopathy. While these substances constitute a physiologic stimulus to reaction in normal persons, they may become pathologic stimuli in other subjects who present a specific neurohormonal dysmorphism.

Hormones and Tumors

At the Medical Academy "Filippo Pacini" at Pistoia, Professor Bruno Borghi, director, general pathologic institute, and acting president of the University of Florence, discussed the relation between hormones and tumors. By examining the experimental data concerning the possible formation of cancerogenic substances directly derived from hormones in the organism, and particularly from sex hormones, the speaker reached negative conclusions, making all similar concepts unworthy of consideration.

With regard to the cancerogenic function exercised by the follicular hormone on the mammary glands, results have demonstrated that the hormone does not act as a true agent of neoplasia but only as an accessory factor which prepares the way for normal phenomena of proliferation in which the cancerous degeneration may be induced by hereditary factors. In strains of mice in which such hereditary factors do not exist the follicular hormone does not produce any neoplasia.

Testosterone does not seem to be endowed with oncoblastic property, either directly or indirectly. The same may apply to the hormones obtained from other endocrine glands including Evans' hormone, which proved to activate normal growth exclusively.

Discussion of Infravirus

At a meeting of the Academy of Science of Ferrara, Professor de Gaetani discussed the problem of infravirus. He emphasized that the study of infravirus may be limited to the special corpuscles capable of provoking a pathogenic action which could be reproduced with the filtrate of the tissue fluid of the affected subject; there may therefore be excluded from this study the true inframicrobes, the filtrable phases of some of the microbes and the lesions produced by some hematophage metazoa. The study of such corpuscles has demonstrated that they are of variable size from 10 to 175 millimicrons; their form is nearly always asymmetric, and they are exceptionally crystalline; membrane and organized structure are missing; the chemical composition is eminently nucleoproteid, and lipids may sometimes be present; they are deprived of water and of respiratory and nutritive activity; their enzymatic system is incomplete. The pathogenic mechanism is a disintegrating one which disturbs the metabolic activity of the cells and may contribute to lysis of the cells or to their proliferation in a granulomatous or neoplastic sense.

As to the nature of infraviruses, one cannot deny that they are an extremely elementary form of life based on an intramolecular rather than an intermolecular organization. One cannot deny, on the other hand, that they are inert in themselves.

MADRID

(From Our Regular Correspondent)

April 25, 1948.

Work of Dr. Pascual

Dr. E. Oliver Pascual, professor at the Madrid General Hospital, has been appointed official discussant to the Inter-American Congress of Digestive Pathology and Nutrition to be held at Buenos Aires. He will discuss "Noncalculous Hepatopathies."

Since 1930 Professor Oliver has done research on many problems of the digestive system and nutrition. By studying deficient diets, especially those lacking in vitamins of the B complex, he proved the appearance of an intestinal dysbacteriosis that increases susceptibility to infection, which in turn sets up dysbacteriosis and demands an increase of vitamins and other factors in the diet. This dysbacteriosis in his opinion is part of a clinical entity, viz., "hepatoenteropathy," and is never absent in any case of hepatoenteric disorder. Dr. Oliver's research on the intestinal flora revealed that in all hepatoenteropathies the organism's requirements of liposoluble and hydrosoluble vitamins and, sometimes, of certain salts are increased. In studying the intestinal flora in patients with deficiency diseases he found salmonellosis in many who have multiple hypovitaminosis. By implanting a normal breed of colon bacilli he succeeded in normalizing nutritional deficiencies and in some cases obtained as good results as those arrived at with sulfaguanidine.

He began the study of dysbacteriosis in 1935 and showed that summer diarrheas are really hepatoenteric reactions in which sometimes the gallbladder plays a part, and sometimes the pancreas or the appendix, while at other times gastric symptoms are lacking even though there is atropic gastritis with achlorhydria.

In recent years, Professor Pascual has concentrated on the pathology of the small intestine, and to him and his collaborators - Arias Vallejo, Torres, Montejo, Luengo, Oliver (Jr.), Galan, Hernandez, Castillo, Costi and Vega Diaz, - priority is due in relation to research on this subject undertaken in Spain. Their papers have appeared in various Spanish journals (*Semana medica espanola, Clinica y laboratorio, Revista clinica espanola,* *Medicina clinica,* and *Revista espanola de las enfermedades del aparato digestivo y de la nutricion,* of the last-named journal, Dr. Oliver Pascual is editor).

New Professors at University of Madrid

After a competitive examination, the Chair of Urology in the Madrid Faculty of Medicine has been awarded to Dr. Alfonso de la Pena, a son of the doctor who until recently held the same chair at Madrid. He has been trained in various centers of Europe and America. A licentiate of the Madrid Faculty of Medicine (1927), he was fellow in urology at the Mayo Clinic, Rochester, Minn., and held a bursary at the Memorial Hospital, New York. For two years he worked in Professor von Lichtenberg's Urology Department in Berlin, where he did research. In 1944 he again visited the North American universities. He is the author of several books and the originator of various technics in his specialty.

Also in a recent competitive examination, Dr. J. Botella Llusia was awarded the Chair of Obstetrics and Gynecology at the Madrid Faculty of Medicine. He succeeds Professor M. Varela Radio, one of the younger masters, who was, however, excluded from his chair from political and personal motives. Professor Botella Llusia, son of a famous Madrid gynecologist, is now taking up teaching in Madrid after having held a similar position (also won by competitive examination) at a provincial university. He brings to his work the strength and all the enthusiasm of his youth.

(From Our Regular Correspondent)

SÃO PAULO, April 23, 1948.

Intestinal Parasitosis in Employees

Based on records from the Institute of Pensions and Retirements for Commercial Employees, Drs. Merrame Adura and Jose Gentil presented a study of the incidence of intestinal parasites in 2,556 employees.

The cases were detected among 14,000 patients attended in 1946 by the Medical Ambulatorium of the institute.

Centrifugation and fluctuation in zinc sulfate, as recommended by Faust and associates, was the method used; they employed also the direct method after a saline purge, whenever required by the physician. There were 3,228 tests made of which 3,145 were by the Faust method and 83 by direct examination. In a majority of cases repetition of tests was necessary for diagnosis (1,038) and in some cases (85) for therapeutic control. Eight hundred and sixty patients manifested protozooses; 295 had worm infestation and 235 showed associated parasitoses; this was a total of 1,480, or about 57.9 per cent of the group studied.

The Institute of Pensions and Retirements for Commercial Employees gives medical aid to industrial employees, teachers, bookkeepers, barbers and owners of commercial magazines.

Drs. Merrame and Gentil said that if the real incidence of amebiasis is considered (as Dacio de Amaral calculated it) then the percentage of results positive for Endameba histolytica will be not 10 per cent but double that figure, and there will be not 57.9 per cent but practically 68 per cent, a high incidence of intestinal parasitoses in large cities. Prominent among the protozooses are amebiasis and giardiasis. Among helminthiases are ancylostomiasis (hookworm), strongyloidiasis, ascariasis (roundworm) and hymenolepiasis. Amebiasis alone showed an incidence of 20.68 per cent.

Clinical signs were, as a rule, varied and generally vague: anemia, vague abdominal pains and constipation. Many patients had not called a physician, but for other reasons, such as getting a small loan, they were subjected to medical examination and a stool specimen sent to the laboratory; it was impossible to find out how many of these persons had been clinically suspected of amebiasis. As to Isospora, no diagnosis of species was made. They found Isospora in 8 carriers among 2,556 patients examined.

High Abdominal Spinal Anesthesia

Dr. Piragibe Nogueira, of the Faculty of Medicine of the University of Sao Paulo, discusses the present situation of high abdomen anesthesia. He believes that there are good indications for spinal anesthesia in selected cases.

Dr. Piragibe's own experience with the high abdomen spinal anesthesia is reported. Until March 1947 its indication was limited to the cases in which the regional anesthesia was thought to be ineffective and the patient showed normal circulation and respiration systems.

Dr. Piragibe mentions his previous papers on the high abdomen spinal anesthesia to call attention to the line of conduct he has adopted since July 1946, viz., to practice it only by the Lemmon process which permits the administration of an initial harmless dosage followed by maintenance doses injected during the course of the operation, considering the muscular tonus of the abdominal wall whose relaxation decreases before the painful sensitivity reappears in the procaine hydrochloride anesthesias.

He discuses the Jones and Sebrechts processes to obtain the high abdomen spinal anesthesia with hypobaric "nupercaine" 1:1,500 and concludes from his own experience that in the Jones process notwithstanding the individualization of the dosages, there is no safety because it is impossible to control the anesthesic level with one dosage only; in the Sebrechts process the gradual application of the dosage which will obtain the desired anesthesia gurantees safety, and Dr. Piragibe has always observed a dosage decrease in comparison with that of the Jones process; however, it was found that the anesthesia period was insufficient.

Studying three series of spinal anesthesia in the high abdomen, he proves, taking in account the causes of the accident, that safety and desirable duration of anesthesia are combined only in the Lemmon technic. Dr. Piragibe has been employing this technic with a 6 per cent procaine hydrochloride solution in the spinal fluid; that solution is clearly hyperbaric.

Dr. Piragibe ends by demonstrating that the Lemmon process permits the Mirizzi's operative cholangiography so valuable in bile duct surgery.

Gastric Cancer

Drs. Francisco J. Nocito and Guillermo F. Cottini from Hospital Alvear of Buenos Aires, Argentina, presented in Rio de Janeiro at the fourth Inter-American Congress of Surgery a study of 213 cases of gastric cancer observed during 1933 to 1947. The number of patients operated on was 190, or 89.2 per cent. Gastric resection was performed on 84, or 39.43 per cent, of the patients. The death rate for gastrectomy was 26.19 per cent. A follow-up of 30 patients showed 8 survivors after more than five years, that is, 26.6 per cent.

Medical Motion Pictures

FILM REVIEWS

Transthoracic Esophageal Diverticulectomy. 16 mm., color, silent, 590 feet (two reels), showing time twenty-four minutes. Prepared in 1948 by and procurable on loan or purchase from Philip Thorek, M.D., 25 East Washington Street, Chicago 2.

This motion picture shows a transthoracic excision of a diverticulum of the lower third of the esophagus. These operations have been made feasible and safe by the development of the antibiotics, by the easy availability of blood for multiple transfusions and by the relatively recent emergence of a school of well trained physician-anesthetists. Formerly infection, shock and respiratory difficulties combined to make the mortality prohibitively high.

The author should omit pointing and gestures in the first part of the film, although such are useful in demonstrating the diverticulum. The color quality is excellent; however, it is obvious that the camera was held by hand. Use of a tripod would have produced a more satisfactory picture. In a few scenes a more advantageous selection of the camera position would have provided a better view of the cavity.

Because the condition is rare, the operation should interest surgeons who do this work; because it demonstrates the case and safety with which such operations can now be performed, it should contribute greatly to their education.

Schistosomiasis. 16 mm., color, sound, 975 feet (one reel), showing time twenty-seven minutes. Prepared in 1946 by the War Department. Procurable on loan from the Army Surgeon of the Army area in which the request originates.

The film touches on the history and geographic distribution of the three types of schistosomiasis, giving good clinical pictures of infected natives and servicemen, demonstrating by animation the route that the parasites take in the body. There are two places where the film could be improved. In the first blood smear the eosinophils are not clear. The second time this is shown, the eosinophils are well brought out. In the smears of the stool it might be wise to use a pointer to indicate the position of the ova. A diagram of the complete cycle would make the subject clearer for those who are not familiar with schistosomiasis.

The photography, including photomicrography is good. The native scenes in regions where schistosomiasis is endemic are colorful and interesting. The close-up scenes of the snails and cercaria are impressive. Several sequences manifest poor photographic reproduction. The animation and narration are also good. This film is suitable for hospital staff meetings and for medical students. It is not intended for the public.

Precancer Diagnosis of Cervix by Cytology. 16 mm., color, sound, 1,300 feet (one reel), showing time thirty-six minutes. Prepared in 1947 by J. Ernest Ayre, M.D., director, Gyne-Cytology Laboratory, Royal Victoria Hospital, McGill University, Montreal, Canada. Procurable on rental from the Clay-Adams Company, Inc., 44 East Twenty-Third Street, New York 10.

The cytologic study of vaginal smears initiated by Papanicolaou has taken the country by storm. Its popularity in medical and to a still greater extent in nonmedical circles has not been an unmixed blessing. This makes particularly desirable a film for thorough instruction in the various technics involved in the study of smears from the vagina and cervix. Few could equal Dr. Ayre's qualifications for doing just that kind of a job.

The film presents case reports, gross appearance of cervical lesions, the technic of obtaining material, making and staining smears, the microscopic appearance of cytologic details, correlation with histologic observations in biopsies and, finally, interpretation. Much of what is shown bears the imprint of Dr. Ayre's own contributions, especially in the method of collecting cervical material. The difficulties of interpretation of borderline cases have not been sufficiently stressed; the lettering on the chart entitled "Ayre's select technic of cytology" is not clear, and the canceled envelop bearing the name of the film's author may be misinterpreted by some observers. These are indeed minor defects in an otherwise satisfying and didactically effective film. In many scenes the color quality of the film is not good. This appears to be the result of poor reproduction of an otherwise satisfactory original picture. The film gives a thorough review of the methods involved.

Miscellany

MEDICAL CARE IN ETHIOPIA

The World Health Organization Mission in Ethiopia has been operating since Jan. 1, 1947 as a continuation of the health activities of the United Nations Relief and Rehabilitation Administration mission in that country. In March the activities and positions of the mission were regularized by the signing of an agreement between the Interim Commission and the imperial Ethiopian government. Ethopia was among the first countries to ratify the constitution of the World Health Organization.

The health needs of Ethiopia are almost limitless. With not a single indigenous doctor or nurse for a population of about 12,000,000, dependence on foreign aid is essential for some years. There are at present some seventy foreign physicians in the country, of whom forty-two are in Addis Ababa, and about the same number of nurses. A committee on medical education recently made what is considered to be a conservative estimate of the needs of the country and put these at about one thousand two hundred medical assistants, three hundred nurses, two thousand dressers and one thousand two hundred sanitary inspectors: altogether, with other auxiliary workers, about five thousand technically trained persons are required.

In the hospitals elementary equipment is often lacking. A female dresser in one of the World Health Organization's nursing classes, which was shown a film on "Bathing the Patient," commented that "we should like to give care like that to our patients but we do not have a washbasin, pan or pitcher in our ward," and this was confirmed by inspection. Sanitation is another vast problem, but fortunately food is abundant and the diet well balanced.

Faced with these problems, the World Health Organization Mission in the closest collaboration with the vice minister of health and his advisers, decided to concentrate on three main tasks: to give elementary training in nursing and sanitation to dressers and sanitary officers; to assist the municipality of Addis Ababa in sanitation; and to assist the ministry of health in investigating and dealing with epidemics in the outlying provinces. These tasks have tried the small staff—originally two doctors, three nurses and a secretary—to the utmost.

Elementary courses for dressers in four hospitals have been completed and a more advanced course begun at the Menelik Hospital. Eighty-five dressers have now received official certificates as a result of examinations by an independent examining board. Help has been given in establishing courses for dressers at hospitals in outlying provinces, and a manual in Ethiopian for the training of dressers has been produced. All reports show the great relief afforded to the inadequate imported nursing staffs of government and mission hospitals by even the most elementary training of local dressers.

Two elementary courses for sanitary inspectors have been completed. The best candidates from both courses will be selected for more advanced secondary training. Both in the courses for dressers and for sanitary officers, and in schools and at public meetings, much use has been made of motion pictures for demonstration purposes. So far, only the surface of the almost virgin soil of Ethiopian health problems has been scratched. The new grant from the United Nations Relief and Rehabilitation Administration for 1948 should, if the government wishes it, allow these unobtrusive yet essential activities to continue and perhaps expand.—*Chronicle of the World Health Organisation,* December 1947.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Application of Federal Food, Drug and Cosmetic Act to Intrastate Sales.—The respondent, a retail druggist in Columbus, Ga., was charged with a violation of Section 301(*k*) of the federal food, drug and cosmetic act of 1938, which section prohibits the performance of any act with respect to a drug "if such act is done while such article is held for sale after shipment in interstate commerce and results in such article being misbranded." The respondent was convicted in the trial court but obtained a reversal of that conviction by the circuit court of appeals (*Sullivan v. United States*,, 161 F. (2d) 629; *J.A.M.A.* 135:53 [Sept. 6] 1947), so the government appealed to the Supreme Court of the United States.

A laboratory had shipped in interstate commerce from Chicago to a consignee at Atlanta, Ga., a number of bottles, each containing one thousand sulfathiazole tablets. These bottles had labels affixed to them, which, as required by section 502(*f*) paragraphs 1 and 2 of the act, set out adequate directions for the use of the tablets and adequate warnings to protect ultimate consumers from dangers incident to this use. The respondent bought one of these properly labeled bottles of sulfathiazole tablets from the Atlanta consignee, transferred it to his Columbus, Ga., drugstore, and there held the tablets for resale. On two separate occasions twelve tablets were removed from the properly labeled and branded bottle, placed in pill boxes and sold to customers. These boxes were labeled "sulfathiazole." They did not contain the statutorily required adequate directions for use or warnings of danger. The circuit court of appeals, said the Supreme Court, interpreted the statutory language of section 301(*k*) "while such article is held for sale after shipment in interstate commerce" as though Congress had said "while such article is held for sale by a person who had himself received it by way of a shipment in interstate commerce."

One reason given by the circuit court for refraining from construing the act as applicable to articles misbranded while held for retail sale, even though the articles had previously been shipped in interstate commerce, was its opinion that such a construction would raise grave doubts as to the act's constitutionality. A restrictive interpretation should not be given a statute merely because Congress has chosen to depart from custom or because giving effect to the express language employed by Congress might require a court to face a constitutional question, said the Supreme Court. When it is reasonably plain that Congress meant its act to prohibit certain conduct, the foregoing reason does not justify a distortion of the congressional purpose, even if the clearly correct purpose makes definite deviations from custom or leads inevitably to a holding of constitutional invalidity. Although criminal statutes must be so precise and unambiguous that the ordinary person can know how to avoid unlawful conduct, they should be given their fair meaning in accord with the evident intent of Congress.

Another consideration that moved the circuit court of appeals to give the statute a narrow construction was its belief that the holding in this case with reference to misbranding of drugs by a retail druggist would necessarily apply also to "similar retail sales of foods, devices and cosmetics, for all these," the court said, "are equally covered by these provisions of the act." The scope of the offense which Congress defined, said the Supreme Court, is not to be judicially narrowed by envisioning extreme possible applications of its different misbranding provisions. There will be opportunity enough to consider such contingencies should they ever arise. Furthermore, continued the Supreme Court, the administrator of the act is given rather broad discretion; for example, he is given extensive authority to issue regulations exempting from the labeling requirements many articles that otherwise would fall within this portion of the act.

When we seek the meaning of section 301(*k*) from its language, said the Supreme Court, we find that the offense which it creates and which is here charged requires the doing of some act with respect to a drug (1) which results in its being misbranded (2) while the article is held for sale "after shipment in interstate commerce." It would require great ingenuity to discover ambiguity in the additional requirement of section 301(*k*) that the misbranding occur "while such article is held for sale after shipment in interstate commerce." The words accurately describe the respondent's conduct in this instance. He held the drugs for sale after they had been shipped in interstate commerce from Chicago to Atlanta, Ga. It is true that the respondent bought them nine months after the interstate shipment had been completed by their delivery to another consignee. But the language used by Congress broadly and unqualifiedly prohibits misbranding articles held for sale after shipment in interstate commerce, without regard to how long after the shipment the misbranding occurred, how many intrastate sales had interveded or who had received the articles at the end of the interstate shipment.

Finally, it was contended that the act as we have construed it is beyond any authority granted Congress by the Constitution and that it invades the power of the states. A similar challenge was made against the Pure Food and Drug Act of 1906 and was rejected in *McDermott v. State of Wisconsin*, 228 U. S. 115. That act, said the Supreme Court, did not contain section 301(*k*) but it did prohibit misbranding and authorize seizure of misbranded articles after they were shipped from one state to another, as long as they remained "unsold." The reasons given for the McDermott holding, concluded the Supreme Court, are equally applicable and persuasive here even though in the McDermott case the labels involved were on the original containers but here the labels are required to be put on other than the original containers—the boxes to which the tablets were transferred, and even though in the McDermott case the possessor of the labeled cans held for sale had himself received them by way of an interstate sale and shipment but here, while the petitioner had received the sulfathiazole by way of an intrastate sale and shipment, he bought it from a wholesaler who had received it as the direct consignee of an interstate shipment. Accordingly the decision of the circuit court of appeals was reversed and the respondent's conviction sustained.—*United States v. Sullivan, 68 S. Ct. 331 (1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied with stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted.

Frozen Precooked Foods.—Proctor and Phillips indicate that within the past decade a new and almost startling array of commercially prepared cooked food has made its appearance in frozen form. The most recent type, frozen precooked foods, was unknown before the war but now may be found in many markets. Frequently these frozen precooked foods have been prepared or manufactured by novices in the field of commercial food packing and processing. In the belief that some information could be obtained relating to the public health aspects of these new products, a microbiologic survey was made of all the commercially prepared frozen precooked foods available in New England markets. Several technics have been developed to aid in the identification of micro-organisms. One of these is a surface-plating technic used in conjunction with impression slides in order to identify large numbers of bacterial colonies more rapidly. Another development is a device to inoculate large numbers of bacteriologic culture tubes simultaneously. Those concerned with frozen precooked foods should set up microbiologic standards for each product and plant control procedures to insure that these standards are maintained. A number of the more experienced companies in this field did this before their products ever went on the market. Some producers have never considered this phase, know nothing about the microbiologic quality of their products and will continue to remain in ignorance unless standards are established for their guidance or control.

Rabies: Vaccination in Dogs.—Korns and Zeissig review the problem of rabies in the state of New York and direct attention to the introduction and spread of the disease in foxes and cattle with a concomitant sharp decline in canine rabies. Thus, during 1946 rabies was reported in 377 dogs, 308 foxes and 440 cows, while during the first nine months of 1947 the disease was reported in only 40 dogs but in 218 foxes and 173 cows. Evidence has been presented that indicates the value of prophylactic canine antirabies vaccination. In ten counties where 78 per cent of the enumerated dogs were vaccinated, the subsequent rabies attack rate in nonvaccinated dogs was 15.8 times the rate in vaccinated dogs observed during the same period and in the same area. Based on experience gained in sponsoring twenty-four county control programs, general recommendations are presented. The authors think that emphasis should be placed on the benefits to be derived from the program by the individual dog and his owner rather than on the legal necessity of complying with the regulations. In the state of New York rabies in cattle seems clearly to have been due to bites from rabid foxes. Control of the fox problem has been attempted by the creation, through trapping, of a zone of fox scarcity surrounding the infected area.

Resection of Esophagus for Persistent Stricture. --Puestow and Chess point out that in stricture of the esophagus various types of procedures have been designed to reestablish the connection between the mouth and the stomach so that food can be chewed and swallowed. They have made a few modifications in the technic of Sweet. By removal of the seventh rib and division of the sixth and fifth ribs, they have found the entire stomach to be accessible and the gastroesophageal anastomosis to be considerably simplified. It has also been their policy to insert a Rawson-Abbott tube through the anastomosis. The proximal end is passed in a retrograde manner up through the esophageal stump to be retrieved by the anesthetist. The distal end is then passed into the stomach, with the extension for feeding well down into the duodenum. Since the vagus nerves are divided in this operation, the stomach becomes greatly distended if constant gastric suction is not used postoperatively. Distention may produce undue tension and necrosis at the suture line, and it also compresses the left lung. By constant aspiration and by the administration of duodenal feedings, the stomach can be kept deflated until healing takes place. At the same time the nutritional status of the patient can be maintained. The authors report 4 cases of intractable stricture of the esophagus with treatment in the described manner. The operation produced satisfactory results in 3 patients; 1 patient died. The authors say that although this procedure may carry with it a higher mortality than more conservative methods of therapy, the end result makes it justifiable as it restores the patient's normal eating habits and frequently overcomes abnormal psychic states. Intensive preoperative and postoperative care is essential for a successful outcome.

Carcinoma of Rectum and Rectosigmoid.--This statistical study by Thomas, Kline and Seed covers all patients with carcinoma of the rectum and rectosigmoid admitted to the Veterans Administration Hospital, Hines, Ill., from 1931 to 1946. There was a total of 844 male patients. The first symptom may be a severe attack of prolapsed thrombosed hemorrhoids. Loss of weight and frequent bowel movements were also frequent symptoms. A number of miscellaneous complaints appeared as the first symptom, such as rectal discharge, fistula in ano, rectal abscess, protrusion, dysuria, rectovesical fistula, weakness, backache and sciatica and the symptoms of metastasis to the liver, lung, groin, brain and jaw. With regard to operability and mortality, the patients have been divided into 2 groups. This division was made because of doubling of the resectability rate, which began in 1940 and was accompanied with a sharp reduction in mortality for all procedures. Several factors were responsible for this improvement. Most important were the better preoperative preparation, with special reference to the maintenance of the fluid, electrolyte and protein balance, the more liberal use of blood and plasma and the use of sulfonamide drugs and penicillin to control infections. During the past ten years, the majority of surgeons in this country have abandoned the two stage resection by colostomy and perineal excision for the one stage combined abdominoperineal resection. Comparing the survival rates after irradiation, after colostomy and after resection, the authors conclude that a carcinoma of the rectum or rectosigmoid should be resected.

Combined Abdominoperineal Resections Without Mortality.--Jones and his associates studied 137 combined abdominoperineal resections of the rectum performed in the Cleveland Clinic Hospital from 1941 to 1943 without operative mortality. They believe that their report will contribute to the growing weight of evidence in favor of the one stage combined abdominoperineal resection as contrasted with operations of lesser magnitude. A thorough abdominal palpation, inspection of the anus, digital examination of the rectum and sigmoidoscopic examination of the rectosigmoid and the lower part of the sigmoid colon made possible a correct clinical diagnosis in 100 per cent of the cases studied. All the lesions were within easy reach of the sigmoidoscope, and 70 per cent were within easy reach of the finger. Roentgenologic study as a diagnostic procedure in carcinoma of the rectum is of little value and may be misleading. For description of the technic of the operation the authors refer to an earlier report. The only change that has been made is the division of the bowel between Cope clamps instead of between Payr clamps and the use of stockinet caps instead of the rubber dam tied over the cut ends of the bowel. The most troublesome complication was infection of the urinary tract and retention of urine. The reasons for this complication seem to be (1) the disturbance of the innervation of the bladder by the removal of the rectum, (2) the use of retention catheter for the first twenty-four hours postoperatively to prevent overdistention of the bladder and (3) the fact that the posterior wall of the bladder has nothing left to push against when contracting because of the removal of the rectum. Most patients began voiding in adequate amounts nine days postoperatively. Residual urine to the amount of over 100 cc. was common for several weeks postoperatively.

Pressure Breathing for Increasing Altitude Tolerance.--Studies described by Eckman and his collaborators revealed that the rise in oxygen saturation during intermittent pressure breathing with air at 16,000 and 17,000 feet (4876.8 and 5181.6 meters) was not accompanied by an increase in mental efficiency, as measured by the Hecht Visual Discrimination Test and the Arithmetical Problem Tests, in the majority of tested subjects. The arterial oxygen saturation in itself is not a dependable criterion of the efficiency of the individual but must be evaluated in the light of the carbon dioxide pressure and the pH of arterial blood. When equivalent mean pressures are compared, intermittent pressure breathing (as obtained by the pneumolator) is less comfortable than continuous pressure breathing. The high incidence of clinical symptoms of alkalosis with intermittent pressure breathing may be dangerous to the aviator. The appraisal of the data thus far reported points to the conclusion that continuous pressure breathing is more dependable and safer than intermittent pressure breathing.

Myocardial Tuberculosis with Paroxysmal Ventricular Tachycardia. R. Schnitzer. -p. 213.

Ergotamine and Apparent Coronary Insufficiency.--Biörck says that since 1942 hypoxemia tests have been done at his clinic as a routine in the clinical examination of patients complaining of symptoms of coronary insufficiency. It was established that the test not only discloses latent coronary insufficiency in many patients with suspected organic coronary heart disease but produced apparently pathologic electrocardiographic tracings in patients with symptoms of cardiac neurosis. The cardiographic observations in the hypoxemia test are usually ascribed to the induced anoxemia or inschemia of the myocardium. The degree of myocardial anoxemia is due to a number of factors, such as ventilation, arterial oxygen tension and arterial pH. Other investigators gained the impression that hormonal influences, reflex mechanisms and, possibly, intermediary tissue metabolism should be considered. This study deals with the influence of the sympathetic nervous system. In 10 patients with positive hypoxemia tests in which it was questioned whether the outcome of the test might not be due to functional factors rather than to coronary sclerosis or myocardial disease, a new hypoxemia test was perfromed after the injection of ergotamine 0.5 mg. In 9 patients the test after use of ergotamine was negative. This points to an effect of the *sympathetic* nervous system in such cases.

Coarctation of Aorta.--Campbell and Suzman point out that the collateral circulation in the chest wall may be the most striking feature of coarctation of the aorta. However, they think that coarctation will often pass unrecognized if a striking collateral circulation is expected to be self evident. It will be diagnosed if the femoral pulse of the patient is felt for and the blood pressure is taken in the legs in every instance of high blood pressure or basal systolic or diastolic murmurs, or undue pulsation in the neck, when this is without an obvious cause. The collateral circulation can be demonstrated in many patients in in whom it is not evident, or it can be made more obvious in others, if the patient is made to stoop forward with his arms hanging down vertically while his back is examined in a good light. This is because the greatly dilated subclavian artery is compressed between the clavicle and the first rib: bending forward opens up the costoclavicular space and thus releases this pressure on the subclavian artery. Any movement that increases the costoclavicular space may elicit this sign. A high pressure in the arms with a low pressure and a poor femoral pulse, or the demonstration of a collateral circulation are pathognomonic of coarctation of the aorta. They are even more important than notching of the ribs, not only because roentgenograms are not always available, but because these signs are present at an earlier age. The rise of blood pressure, the collateral circulation and the notching of the ribs develop as a rule in those between the ages of 6 and 16 years. The rise of blood pressure and the increase in the collateral *circulation* occur during the period of rapid growth, probably because the *stenosis* of the aorta does not increase in cross section (or increases relatively little) with the growth of the rest of the aorta; hence, the relative obstruction becomes *greater*. More than half the patients had little or no clinical or radiologic enlargement of the heart. Enlargement was more likely when there was an aortic diastolic *murmur* (6 of 15 cases), though even then it was sometimes slight. The average expectation of life of those with symptoms before adult life is probably no more than thirty years, so that cure by operation has something to offer. Where the diagnosis is made for the first time in adult life, and especially in those without symptoms, the outlook is relatively good.

Preoperative and Postoperative Roentgen Treatment.--Radical operation was done in 123 cases of cancer of the breast with postoperative roentgen treatment and in 53 cases with preoperative roentgen treatment as well. Ninety-nine patients were examined at least five years after the operation; 4 had died from intercurrent disease. In 38 patients there was no recurrence, 61 had recurrence. Of the 29 patients without axillary metastases, 24 had no recurrence; of the 70 with axillary metastases, 14 were free from recurrence. Fifteen per cent of the recurrences appeared after three years. In 21 per cent of the recurrences the supraclavicular nodes were invaded. Extension of the operation to include extirpation of the supraclavicular nodes is advised. No better effect was seen *from* preoperative and postoperative roentgen treatment than from postoperative roentgen treatment alone.

Intestinal Atresia.--Brynjulfsen discusses atresia in the small and large intestine and reports 2 cases localized to the duodenum, both fatal; a case of multiple occurrence, also fatal, and a case of atresia of the small intestine with recovery after anastomosis, believed to be the ninth case of its kind with recovery to be published. To 1941, 20 cases of duodenal atresia with recovery had been published (Windfeld). Treatment is operative. With atresia in jejunum and ileum the method of choice is side to side anastomosis. The author cautions against jejunostomy and ileostomy. Three cases of atresia ani are described, 1 with recovery, 1 with incontinence and 1 with the formation of stricture.

Renal Functions in Hyperthyroidism and Myxedema.--In studies on the specific renal functions in 2 patients with hyperthyroidism, 1 of whom was treated by subtotal thyroidectomy and the other with thiouracil, Corcoran and Page found that this condition is not associated with a significant renal vasodilation or with an increase in tubular secretory capacity for iodopyracet injection ("diodrast" N.N.R.) proportionate to the elevation of the basal metabolic rate. Before treatment, 2 patients with myxedema treated had reductions of renal blood flow, glomerular filtration and tubular secretory capacity. Treatment with desiccated thyroid resulted in restoration of these functions toward normal. The changes thus induced in renal blood flow and glomerular filtration rate reflect a decrease in afferent vascular resistance. The depression of tubular secretory capacity in myxedema is excessive in relation to the reduction of basal metabolic rate in this condition and to the changes observed in this function during hyperthyroidism. It is suggested that the renal functional depression present in myxedema is in part a reflection of depression of anterior hypophysial function rather than a direct renal lack of thyroidal hormone.

Control of Respiratory Infections in Industry.—Wilkins thinks that the time-honored advice given to a patient with an acute respiratory infection to "go to bed for twenty-four or forty-eight hours" is undoubtedly of merit. Although in the absence of fever it is questionable whether such a procedure shortens the duration of the infection, it serves to isolate the patient and thus to prevent spread by contact. The observance of general hygienic measures, such as the use of disposable tissues for coughing, sneezing and nose blowing, and cleanliness of the hands, requires no comment. Education may be accomplished by the use of posters, pamphlets and articles in company organs in which personal hygiene, proper clothing, nutrition, exercise and rest are stressed. To date no scientific evidence has been presented that additional vitamins have any immunologic value in the presence of a diet that supplies the minimal daily requirements of these accessory food factors. Experience with cold vaccines has convinced the author that the method is of no value as a preventive measure against colds. The Subcommittee for the Evaluation of Methods to Control Airborne Infections concluded that the general use of ultraviolet irradiation or disinfectant vapors in schools, barracks and in industrial environments is not justified at the present time. In a recent outbreak of influenza, definitely identified as due to virus A, vaccination of 10,000 university students was accomplished. Satisfactory serum antibody levels against virus A were obtained, but no protection was afforded.

Rheumatoid Arthritis.—Short and Bauer review observations on 250 unselected patients with rheumatoid arthritis who received simple medical and orthopedic measures and who have been under observation for an average period of ten years. Over 50 per cent evidenced definite improvement when last seen, and 15 per cent were considered in remission. The authors hope that additional series will be collected and published for comparison with this one and with results attained by special forms of therapy. No selection should be used and, if possible, the patients should represent consecutive admissions. In this way the series will not be limited to certain types or stages of the disease. The follow-up period should be spread over years rather than months to allow for the usual relapses and remissions. When the time has come for the evaluation of results, certain factors of prognostic implication should be taken into consideration. These include the age and sex of patients, the duration of the disease, the type and extent of involvement and the activity and severity of the process. It is desirable that a uniform scheme for the evaluation of therapeutic results eventually be adopted. The results in the present series indicate that about 50 per cent of patients will ultimately improve. This percentage may well change in the course of time. The percentage obtained at present is below "the inevitable 75 per cent improvement" usually mentioned in estimates on the prognosis in rheumatoid arthritis.

Book Notices

Rhinoplasty and Restoration of Facial Contour with Special Reference to Trauma. By Jacques W. Maliniac, M.D., Clinical Professor, Plastic Reparative Surgery, New York Polyclinic Medical School and Hospital, New York. Cloth. Price, $7.50. Pp. 327, with 211 illustrations. F. A. Davis Company, 1914-16 Cherry St., Philadelphia 3, 1947

In the preface the author states "I have not sought to restate facts which can be found in any standard textbook but rather to furnish practical data in which much of the current literature is deficient." In chapter X he states "This chapter will stress those points which in the author's opinion need clarification and improvement." Later in the same chapter he states "As throughout this book, details of accepted procedures which have been repeatedly described elsewhere are omitted here. Emphasis is laid on controversial points and methods which personal experience has found of particular value."

Thus the reader who is seeking a textbook giving details on the performance of routine rhinoplastics will be disappointed. The emphasis in this book is on trauma, both in its acute stage and in its late effects, the minimization of deformity and the correction of that which has already developed. In the chapter on anatomy and development the anatomy of the bony framework and external nose is presented, with emphasis on the relation of anatomy to deformity and external contour. The necessity for a thorough and accurate diagnosis prior to the treatment of acute injury and the technic of examination and evaluation of this injury are stressed. Nasal fractures with associated injury to the soft tissue and cartilaginous displacement are discussed in fullest detail, as is the treatment of each displacement or element in the deformity.

A chapter on skin grafts, flaps and supporting grafts lists the various types of grafts to be thought of and utilized in making a repair. It does not describe the detailed technic for using these grafts or performing the operations but does give good advice in helping the reader to select the procedure of choice.

The relationship of septal malformation to external deformity is well presented. The discussion of nasal asymmetries, associated oversized deformities and traumatic nasal loss again does not give detailed technics but rather lists the possibilities for repair and gives the author's preferred technic. This portion of the book is written with far less emphasis than is the section on treatment of acute trauma.

There are a number of inaccuracies in the recommendations for the use of sulfonamide drugs, penicillin and tetanus toxoid. The reader should not let such minor discrepancies prejudice him against the valuable portions of the book.

Kurzes Handbuch der Ohrenheilkunde. Von Professor Dr. Hermann Marx. Second edition. Boards. Price, 48.50 marks. Pp. 888, with 499 illustrations. Gustav Fischer, Villenz 2, Jena, Deutschland, Russ. Zone, 1947.

This short handbook is in its second edition and is wholly devoted to the diseases of the ear. It is well printed on paper of fine quality with many of its illustrations in color. The author considers his subject in great detail; his statements are authoritative. Considering Germany's state during and since the last war, this text is a tribute to the courage and zeal of the author. Of course, and with all this in mind, there are deficiencies. These relate to the inability of German workers to keep abreast of recent advances, especially in American medicine. For this reason the treatment of a number of subjects is necessarily scanty and behind the times. For instance, our notions about and our treatment of aural vertigo of the Ménière's syndrome type, as well as the tremendous impact of antibiotic therapy on the surgery and treatment of suppurations of the temporal bone and their complications, are not reflected in these pages. Penicillin is not even mentioned in the index. The discussion of fenestration technic in otosclerosis is heavily weighted in favor of European investigators and thus overlooks the high degree of skill and success with which these procedures are carried out in this country by Lempert and others whom he has influenced. Nevertheless the sober student of otology ought to possess and prize this work as a fine and almost indispensable guide to the background of an art and practice which has changed remarkably in the last few years.

Hypnotherapy: A Survey of the Literature. By Margaret Brenman Ph.D., Director of the Division of Psychology, the Menninger Foundation, Topeka, Kan. and Merton M. Gill, M.D., Associate Psychiatrist, Assistant Director, Department of Research, the Menninger Foundation. With Appended Case Reports and an Experimental Study. The Menninger Foundation Monograph Series No. 5. Cloth. Price, $4.50. Pp. 276. International Universities Press, 227 W. 13th St., New York 11, 1947.

One half century after therapeutic hypnosis was discarded by Freud, a revival of interest has occurred. The authors of this interesting and stimulating book review the literature and bring up to date the theories, indications and applicability of hypnotic procedures in psychotherapy. The volume is divided into three sections. The first portion is designed to clarify present knowledge by a survey of the literature. The second and most interesting section presents four case studies, previously published in various journals, which clearly demonstrate the methods of investigation. At the beginning of therapy free association while under hypnosis was utilized. Then the authors worked with spontaneous dreams, dreams induced by suggestion when resistance appeared or when a clearer statement of the material was desired. In addition to free association and dreams the therapists attempted to force the recall of forgotten memories. Toward the end of therapy technics under hypnosis to induce regression played a significant role. They explored specific trends by reviving episodes which the history indicated were closest to the repressed content. The patient was regressed to this episode and hitherto repressed material was explored. Repression seemed to yield most readily to hypnosis. Other defense mechanisms could also be analyzed under hypnosis as in the waking state. To counteract anxiety, which at times made its appearance during the release of repressed material, direct supportive suggestion was used. The third section deals with the possible uses of hypnosis in psychologic investigation. This book is a valuable contribution to the therapeutic technic in psychiatry. Hypnosis is not in itself therapeutic. The skill of the therapists in the utilization of the transference and dealing with the ventilated material are of paramount significance.

The Foot and Ankle: Their Injuries, Diseases, Deformities and Disabilities. By Philip Lewin, M.D., F.A.C.S., Associate Professor of Bone and Joint Surgery, and Acting Head of Department, Northwestern University Medical School, Chicago. Line Drawings by Harold Laufman, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School. Third edition. Cloth. Price, $11. Pp. 847, with 389 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1947.

In this third edition the author has added measurably to his already highly comprehensive work. There is a new section of considerable length on the military aspect of the foot based on such facts and experiences as were collected during the last war. While the traumatic aspect of foot ailments is given extended consideration, it does not curtail a thorough and comprehensive treatment of other conditions such as the static and inflammatory ailments. Furthermore, subjects that are so easily overlooked in textbooks because they are presumably insignificant, such as infections and abnormalities of the toenail, foot hygiene, chilblain and frostbite, are thoroughly discussed and are a welcome addition to the surgeon who may be looking for real advice on the minor ailments of the foot and may find the usual textbook disappointing. The book is written with the same thoroughness that characterized the earlier editions.

Disfunciones motoras del estomago. Por el Doctor E. Arias Vallejo. Prólogo del Profesor E. Oliver Pascual. Paper. Price, 35 pesetas. Pp. 155, with 66 illustrations. Revista española de las enfermedades del aparato digestivo y de la nutricion, Cava Baja 11, Madrid, 1947.

Arias Vallejo has made a particular study of those cases in which the stomach fails to empty properly, and he has covered the literature fairly extensively. Each chapter has a bibliography appended. The first chapter deals with the physiology of gastric emptying. Following this there are chapters on stenosis near the pylorus, duodenal stenoses below the papilla, spasm of the pylorus, weakness of the gastric walls, gastric ptosis, the slow emptying of the stomach in some diseases of the small intestine; acute dilatation of the stomach, and the emptying of the stomach after operations on this organ. Few persons realize that in some cases of diarrhea the stomach empties slowly, perhaps because of irritation of the small bowel. This is a creditable piece of work and all Spanish-speaking physicians can find a good deal of value in the volume.

Industrial Health Engineering. By Allen D. Brandt, B.S., M.S., Sc.D., Industrial Hygiene Engineer, Bethlehem Steel Co., Bethlehem, Penn. Cloth. Price, $6. Pp. 395, with 167 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, 1947.

This book is described as the first complete handbook on industrial atmospheric contaminants and their control. Presumably, this statement refers to literature available to engineers. The material is especially designed for that profession and will appeal only to those physicians who have qualified as industrial hygienists or who are called on to install, administer or supervise measures for the control of occupational hazards.

Plague: Laennec (1782-1826) Inventor of the Stethescope and Father of Modern Medicine. By Arthur N. Foxe, M.D. Second edition. Cloth. Price, $2.50. Pp. 122, with 2 portraits. The Hobson Book Press, 52 Vanderbilt Ave., New York 17, 1947.

According to the author's brief preface, this volume is the second edition of the book whose first edition (1930) was limited to "six copies." It seems questionable whether everyone would agree with the author that his medical hero is the "father of modern medicine," as stated in the title. Whereas the best biographic history should be written from the point of view of the times in which the person lived, one can certainly affirm that this volume is so written; for the book is replete with philosophic references to the turbulence in France during the student days and professional activities of Rene Laennec. To cite an example: "And his (Carrier's) people had objected violently that children of the nobles would eat tarts that rightfully were only for their own. Later when men tired of killing, looked about and could see only error where before they had only seen right, it was on Carrier that the brutal acts of everyone were to be heaped" (p. 22). More in line with the subject of his biography is the evaluation of the teachers of Laennec, where the author writes: "This man had charm and his words flowed smoothly, but to what depth? This man shouted his students to submission but his shouting concealed a narrowness and weakness of outlook. This man spoke calmly, openly, confidently, but no igniting demon even slept within him" (p. 71). Of this sort of material there seems to be a surfeit. Laennec's brief life (he died at 45), with its psychic ups and downs, runs as a thin thread through a heavy matrix of philosophic considerations, so much so that one finds as much biographic material on page 151 of Camac's "Epoch-making Contributions" as in the first seventy-one pages of the present book, even though one probably will find nowhere else so impressive an account of the poverty of Laennec and his alternate periods of happiness and depressions. The final months and days of Laennec succumbing to pulmonary tuberculosis are particularly well and graphically portrayed by Dr. Foxe. In spite of too much irrelevant material the book makes interesting reading of this great discoverer and can be easily read in an afternoon.

Clinical Neuro-Ophthalmology. By Frank B. Walsh, M.D., F.R.C.S., Associate Professor of Ophthalmology, Johns Hopkins University, Baltimore. Cloth. Price, $15. Pp. 1532, with 384 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

English-speaking ophthalmologists and neurologists have been waiting a long time for this book. Previous texts had the shortcomings of being either too brief and incomplete or in a foreign language, particularly German. If there is anything missing, pertinent to the title of this excellent work, the reviewer has been unable to uncover it. It is a veritable encyclopedia of neuro-ophthalmology in one volume and represents a wealth of painstaking and accurate work on the anatomy, physiology, pathology, signs, symptoms and treatment of all neurologic disorders affecting the eyes. The author has had the privilege of close association for many years with various departments, notably neurologic and neurosurgical, of the Johns Hopkins and Baltimore City hospitals. He has devoted ten of these years to the production of this work and has arranged his voluminous and important material with skill and grace. His style is austere yet pleasing, and difficult phases are treated with lucidity. The index is superb. Every physician will discover the volume to be of much value and significance in his daily work.

Handbook on Fractures. By Duncan Eve Jr., M.D., F.A.C.S., Surgeon in Chief, Nashville, Chattanooga and St. Louis Railroad, Nashville, Tenn. In collaboration with Trimble Sharber, A.B., M.D., Attending Surgeon, St. Thomas Hospital, Nashville, Tenn. Cloth. Price, $5. Pp. 263, with 129 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1947.

This small book covers in a succinct and brief way the general management of fractures. In spite of its brevity it includes a good many detailed descriptions that are important if one wishes to treat fractures satisfactorily. The descriptions are short and to the point. If there is criticism to be made, it might be that too much emphasis is laid on roentgenologic examination and not enough on tenderness. There are a great many fractures without displacement which are not revealed on early roentgenologic examination. In fractures of the femur there is one point that might well have been emphasized; that is, the preservation of the crown of the femur. Most of the illustrations are good, but some of the roentgenograms seem a bit foggy. There is one point of view which some authorities might disagree on; a fracture of the cuboid bone does not need a plaster cast. A felt pad 1/2 inch (1.27 cm.) thick placed under the sole from the heads of the metatarsals to the os calcis will relieve pressure and make it possible for the patient to walk about while the fracture is uniting. This is a valuable book for the medical student and for those practitioners who encounter fractures but do not have time to read about them in great detail. On the whole, the emphasis is laid on conservative methods rather than on gadgets. This is a healthy attitude at this time when so many surgeons are using metal in treating fractures. Those interested in the treatment of fractures will find Dr. Eve's book a useful addition to their libraries.

Sir W. Arbuthnot Lane, Bart., C.B., M.S., F.R.C.S.: His Life and Work. By W. E. Tanner, M.S., F.R.C.S. Cloth. Price, $4.50. Pp. 192, with portrait. The Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1946.

Sir W. Arbuthnot Lane will probably be remembered for Lane's kink, which was a mistake, and for his subsequent embarkation into notions regarding diet and health, which were probably even greater mistakes. He should be remembered as a great surgeon who in his prime was recognized throughout the world. He should be remembered for his development of the metallic plates and implements which continue to be used in surgery. His biographer believes that some of the statements made by Lane in his later years which were so greatly attacked were made with his tongue in his cheek simply to startle the medical profession. The biography is worthy of note as a study of one of the most interesting characters in modern medicine.

The Christchurch Hospital Medical Manual. Edited by C. T. Hand Newton, D.S.O., M.D., F.R.A.C.P. Second edition. Cloth. Price, 15s. Pp. 109, with 1 illustration. N. M. Peryer Limited, 145-147 Worcester St., Christchurch, C. 1, New Zealand 1947.

This manual, prepared for the guidance of the visiting and house staffs, nurses and dietitians, concentrates mainly on the use of roentgenologic and laboratory services as aids to clinical diagnosis and therapy. Articles have also been included on fluid balance, hypersensitivity to serum and the use of blood and plasma in clinical practice. Approximately half of the book is devoted to general and special diets which can be employed routinely or in modified form to meet individual needs. The book has become a convenient and informative source of reference for the medical and hospital personnel.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CARBOHYDRATE ALLERGY

To the Editor:—A woman aged 51 complains that she is "allergic to sugar or carbohydrates and has been for the past eighteen or twenty years." When she eats sugar there develop edema of the ankles, swelling of the abdomen and puffiness of the face and hands. After the ingestion of carbohydrates she has nocturia seven or eight times. Physical examination was negative except for a hypotension of 90 systolic and 60 diastolic, a bradycardia of around 48 and hypoactive reflexes. An electrocardiogram and a roentgenogram of the gallbladder revealed normal conditions. On roentgen examination the chest was normal except for a few adhesions of the left costophrenic angle. The upper part of the gastrointestinal tract was normal; study of the lower part of the gastrointestinal tract revealed a congenital megacolon (or Hirschsprung's disease). Urinalysis was negative; blood sugar and nonprotein nitrogen were within normal limits. Hippuric acid test of liver function was within normal limits. Gastric analysis disclosed a tendency towards achlorhydria. The blood count was within normal limits and the Wassermann test was negative. The basal metabolic rate was minus 23 per cent. Skin tests were positive for cane sugar, beet sugar, lactose, dextrose and a few other miscellaneous foods. She has learned through trial and error what to eliminate from her diet. Thyroid "depancol" (each enteric-coated tablet contains 0.022 Gm. dihydrocholic acid, 0.292 Gm. pancreatin and 0.097 Gm. bile salts), vitamins, amino acids, "pyribenzamine," prostigmine and hydrochloric acid have been used in treatment. Would a sympathectomy cure her? She lost about 12 pounds (5.4 Kg.) and now weighs only 110 pounds (49.9 Kg.). Her diet is becoming more limited and is restricted to proteins and fats only.

M.D., California.

ANSWER.—The solution is not obvious. The patient's statement that she is "allergic to sugar or carbohydrates" is probably incorrect. Allergy to sugars is rare, if it occurs at all The positive reactions for extracts of cane sugar, beet sugar, lactose and dextrose should be proved, because in the hands of almost all allergists skin tests for these carbohydrates are uniformly negative whether carried out by the scratch or the intradermal method. Mention of allergy to sugars is not found in standard textbooks on allergy by Coca (Coca, A. F.; Walzer, M., and Thommen, A. A.: Asthma and Hay Fever, Springfield, Ill., Charles C Thomas, 1931), Tuft (Tuft, L.: Clinical Allergy, Philadelphia, W. B. Saunders Company, 1937) or Unger (Unger, L.: Bronchial Asthma, Springfield, Ill., Charles C Thomas, 1945). Vaughan (Vaughan, W. T.: Practice of Allergy, St. Louis, C. V. Mosby Company, 1939, p. 354) has stated that "the possibility of allergy to the refined sugar is decidedly questionable. The writer has seen a few patients who have been convinced in their own minds that one or another kind of sugar has been responsible for allergic manifestations. The possibility exists, of course, that some other food article ingested with the sugar may have been the responsible excitant," e. g., chocolate, almond, cocoanut or peanut. Vaughan has said that skin tests are negative for sugar, but he has quoted cases of allergy to sugar as reported by Rowe and Duke.

Urbach and Gottlieb (Urbach, E., and Gottlieb, P. M. Allergy, Grune & Stratton, New York, 1946, pp. 313-314) stated that allergy to carbohydrates is rare and probably based on a haptene mechanism, while intolerance to carbohydrates is a metabolic disorder generally considered to be a forerunner of diabetes. In either case administration of sugar leads to generalized or cutaneous symptoms which disappear when carbohydrates are avoided. To differentiate, sugar is again given when the patient is symptom free, but this time after an adequate injection of insulin. If symptoms do not occur the case is due to carbohydrate intolerance (latent diabetes); if symptoms occur the diagnosis is hypersensitivity. Urbach and Gottlieb have reported 2 cases in which eczematoid, pruritic dermatitis was aggravated by carbohydrates and relieved when carbohydrates were removed from the diet of the patients.

Avoidance of dietary carbohydrates may not be harmful, as shown by the polar explorer, V. Stefansson, who was in excellent condition after a diet of meat and its fats through a twelve month period.

The hypothyroidism may be important here; continued administration of thyroid seems definitely indicated. Other endocrine therapy, e. g. estrogenic, may also be of service. Sympathectomy is not indicated. Dextrose tolerance tests, examination of the eye grounds and a neurologic search for possible tumor of the brain are in order. To test the patient's complaints, dextrose could be given disguised in capsules; if symptoms did not develop, dextrose could then be tried subcutaneously and then intravenously. The possibility of allergy as a factor would be strengthened by the presence of blood eosinophilia and by the presence of some allergic symptoms in the family or a recognized allergic condition in the patient.

CHOLINE

To the Editor:—What is the information on use of choline? Are there harmful results from its use in patients with high blood cholesterol levels? What are other indications and dosage for use of choline?

M.D., Oklahoma.

ANSWER.—Choline, which is commercially available as choline dihydrogen citrate, has been shown to have a lipotropic action. The effect on blood cholesterol levels is negligible. This substance cannot be relied on to reduce a high blood cholesterol to a normal or near normal level or to prevent hypercholesterolemia.

Choline dihydrogen citrate has been accepted for inclusion in "New and Nonofficial Remedies" for the treatment of hepatic disease associated with fatty infiltration. Although animal experiments indicate a favorable action of choline, clinical studies have been inconclusive. Furthermore, it has yet to be conclusively demonstrated that choline therapy is superior to an adequate diet in the treatment of hepatic disease.

Choline should always be given orally, and by that route it is practically nontoxic. It should be noted that most foodstuffs contain substantial quantities of choline. Parenteral administration of choline is dangerous and may lead to circulatory collapse.

The recommended dose of choline dihydrogen citrate is 2 to 3 Gm. orally in divided doses.

ALUM PRECIPITATED DIPHTHERIA VACCINE

To the Editor:—What is the information on abscess formation from alum precipitated diphtheria vaccine? I have had 2 cases of abscess formation following use of the vaccine in patients aged 36 and aged 2 years. What is the treatment?

George U. Ivers, M.D., Fargo, N. D.

ANSWER.—A great deal of improvement has been made in the preparation of diphtheria toxoid fluid and diphtheria toxoid, alum precipitated, during the past year. An alum precipitated toxoid in which the alum content is claimed to be reduced by 75 per cent is now available. Toxoids prepared in this manner are said to be practically free from reaction in both children and adults. The dosage required is only about one half the volume customarily used with the standard toxoids. Therefore local reactions caused by the alum are reduced to a minimum.

When an abscess forms after administration of diphtheria toxoid, alum precipitated, absence of redness of the skin indicates that the abscess is probably sterile. Therefore, if it is not interfered with its absorption may be expected. If the abscess is the result of infection, treatment is the same as for any other superficial abscess.

SCARLET FEVER IMMUNIZATION

To the Editor:—How effective is scarlet fever streptococcus toxin (as Wyeth's) in preventing scarlet fever? Does it prevent the complications of scarlet fever? Are there any disadvantages or contraindications against active immunization against scarlet fever?

M.D., New Mexico.

ANSWER.—Scarlet fever streptococcus toxin is of undoubted value for the prevention of the classic form of scarlet fever. Scarlet fever toxin when given in proper dosage will establish immunization against the rash of scarlet fever but does not immunize the recipient against infection with scarlet fever streptococci. Although scarlet fever streptococcus toxin when given for active immunization may prevent toxic manifestations of the disease, it does not eliminate the possibility of suppurative complications. Occasionally there is some unpleasant reaction following the administration of scarlet fever toxin when immunization procedures are carried out.

If a patient is immunized against the toxic manifestations of scarlet fever, including the rash, the necessity for isolation of such a patient when he has an acute case of pharyngitis due to scarlet fever streptococci is not appreciated. Therefore it might be assumed that persons inoculated with scarlet fever toxin could become a hazard to a community: although they harbored scarlet fever streptococci they would have no rash and consequently would not be isolated. Therefore they might transmit clinical scarlet fever to nonimmunized persons.

BLOOD IN NEWBORN

To the Editor:—Discuss and give references concerning the belief that many ounces of blood will be gained by the newborn child if the cord is not cut till its pulsations stop or by milking the blood into the child by stripping the cord toward the child.

M.D., New York.

Answer.—The studies of Q. B. DeMarsh, H. L. Alt and W. F. Windle (The Journal, June 7, 1941, page 2568) have definitely shown that deprivation of the infant of the portion of its blood that is in the placenta by clamping the umbilical cord immediately after birth influences the red corpuscle count and hemoglobin content of the blood during the first week of life. Those infants whose cords were not clamped until the placenta had separated from the uterus had on the average 0.56 million more red blood corpuscles per cubic millimeter and 2.6 Gm. more hemoglobin per hundred cubic centimeters during the first week of life than those whose cords were clamped immediately.

Blood drawn from the infant's navel twenty to seventy-five minutes after birth had significantly higher red corpuscle and hemoglobin values than blood drawn from the umbilical cord at birth. Possibly the spleen plays a part in bringing on this polycythemia of birth. Higher reticulocyte counts in infants whose cords were clamped immediately suggested a greater demand for blood in this group than in the group whose cords were not clamped until placental separation. Early clamping of the umbilical cord is equivalent to submitting the child to a hemorrhage at birth.

The editors of the "1941 Year Book of Obstetrics and Gynecology" made the following comment concerning this article: "The same authors have also proved that such deprivation of placental blood may lead to an iron deficiency which may persist during the first year of life (Am. J. Dis. Child. **62**:320 [Aug.] 1941). For this reason some operators force the placental blood into the baby's circulation by stripping the cord. This can be dangerous if done roughly—forcing blood into an already full circulatory system causing heart block and rupture of fine vessels. In earlier times we ascribed melena neonatorum to this practice. The baby will get the blood it is entitled to if you wait a few minutes before clamping or tying the cord."

ALLERGIC RHINITIS

To the Editor:—In August 1946 my daughter, aged 16 years, contracted allergic rhinitis, apparently following a severe head cold.

She had intravenous histamine therapy without result. Diphenylhydramine hydrochloride ("benadryl") gives her temporary relief but makes her drowsy. Packing the nostrils with mild silver protein ("argyrol") 10 per cent seems to help a little. She sneezes a great deal night and morning. What other treatment is suggested?

De Vere Ritchie, M.D., Orlando, Fla.

Answer.—The history does not contain sufficient data for a diagnosis. If diagnosis is definitely allergic rhinitis the next step before treatment (other than palliative) is to make an etiologic diagnosis. Home environmental substances to which the patient may have become allergic, or the seasonal and perennial allergens in the air (pollens, molds) may be causes of this condition. Food sensitization may aggravate inhalant causes. Have a competent specialist in allergy determine the causes of the condition. Treatment will then depend on the offending causes.

Use of mild protein silver packs in allergy is certainly contraindicated. It will lead to chemical irritation of an already irritable, hypersensitive mucosa. Use of histamine in the treatment of nasal allergy is considered by many allergists to be of questionable value.

FALSE POSITIVE FREI TEST

To the Editor:—What is the information on false positive Frei tests with all antigen? Please furnish recent references on this subject.

M.D., Maine.

Answer.—A false positive Frei test may occur with antigen of human bubo origin, chick embryo origin or mouse brain origin. When employing antigen of chick embryo or mouse brain origin controls should be run with uninfected materials. False positive reactions are sometimes obtained during the acute phase of one or another of the other venereal diseases, i. e., syphilis and chancroid, and may occur in patients who are highly allergic. In the presence of a suspected false positive reaction a complement fixation test will help to rule out the disease.

POSTCOITAL HEADACHE

To the Editor:—A Negro woman aged 25, married eighteen months, has been suffering for the past sixteen months with moderate to severe postcoital backache, in the right lower quadrant and severe headache in the right frontotemporal region. Headache also occurs occasionally on the left side.

Two months after marriage, she had symptoms of nausea, epigastric pain and flatulence after meals. Examination revealed a six weeks pregnant uterus. The uterus showed second degree retroversion, which appeared to be congenital but had given the patient no previous trouble. The flatulency became worse, and the abdomen was distended beyond normal proportions. Two months later the patient had an attack of severe gastrointestinal distress with vomiting and diarrhea, at which time she apparently lost the fetus. One month later the uterus was empty. Continuous headache was relieved temporarily but soon returned. She also complained of hot flushes, which are becoming less frequent.

The patient was examined by a specialist in February 1946. He told her that her condition was due only to change in climate and to adjustment of her body to married life. He prescribed diethylstilbesterol and thyroid, which gave her relief for about three months, after which the headache, backache and gastrointestinal distress returned. The patient lived in a dry climate before marriage but now lives in a moist climate; the color of her skin becomes lighter and menstruation becomes prolonged whenever she returns to the dry climate. In a recent Aschheim-Zondek test her urine was toxic and killed an animal.

I believe the cause is partly climate and partly psychic; however, I have discontinued treatment pending consultation. Please discuss this case and suggest treatment.

M.D., Massachusetts.

Answer.—The symptoms do not appear to be caused by any gynecologic abnormality, and apparently none was found by the specialist. This patient should have a complete investigation of the gastrointestinal tract wi[illegible] No reason for giving diethylstilbestrol [illegible] uld not be administered unless basal [illegible] the need for it.

MALIGNANT MELANOMA

To the Editor:—Some months ago an apparently otherwise healthy person came to me with a nevus on the left temple which was breaking down. I destroyed it with the electric needle under procaine anesthesia including the surrounding area to the extent of about a 5 cent piece. The wound healed satisfactorily and the patient had no further symptoms for three or four months when the parotid gland became greatly enlarged and quite dense. Diagnosis of malignant melanoma with metastases to the lungs was made. The roentgenologist studied films of the lungs made prior to my destruction of the growth on the temple and concluded that they showed evidence of metastasis. Hard lumps are now scattered anteriorly and posteriorly under the skin of the abdomen and chest. The man works regularly and says that he feels well.

Is there a presumption that destruction of the nevus was incomplete and was responsible for the subsequent rapid development of the parotid tumor and its widespread metastasis? Should surgical measures have been avoided at that time? The roentgenologist believes that metastasis was present in the lungs prior to destruction of the nevus, but he admits that it is only an opinion and not a certainty.

M.D., Pennsylvania.

Answer.—There is a strong suspicion that inadequate treatment of a nevus can lead to disseminated melanoma. The evidence in this case seems to indicate that the dissemination was not related to the treatment.

ENDOMETRIOSIS

To the Editor:—In patients with endometriosis who are approaching the menopause, is there objection to using estrone for menopausal symptoms during and after menopause? This patient has two or three years to go before menopause is established. She has chocolate cysts and at present has no symptoms.

M. Karasek, M.D., Shidler, Okla.

Answer.—To clarify terms and definitions, menopause is that period when menstruation normally ceases and is established with the last period. The term menopause, or menopausal syndrome, is more loosely applied to that period from the terminal menstrual period until hot flushes and vasomotor symptoms cease, usually varying from six months to three years. Women with enough ovarian function to menstruate will not have menopausal symptoms, and some women apparently produce enough estrogen to relieve menopausal symptoms past the time of the last period.

Endometriosis should be thought of in exactly the same light as endometrium of the uterus. Anything (estrogen) that will stimulate endometrium will cause areas of endometriosis to grow or proliferate. Therefore, the use of estrogen is usually contraindicated in any phase of this disease.

Chocolate cysts are usually diagnosed at the time of surgical intervention and may have an etiologic basis other than endometriosis. Pain usually accompanies endometriosis.

SYMPATHETIC INNERVATION OF THE HEART IN MAN

Preliminary Observations of the Effect of Thoracic Sympathectomy on Heart Rate

EARLE M. CHAPMAN, M.D.,
DERA KINSEY, M.D.,
W. P. CHAPMAN, M.D. and
REGINALD H. SMITHWICK, M.D.
Boston

Control of the heart rate in man has long been sought. Slowing of the rapid heart rate has been attempted by several methods, the common one being the use of body rest and drugs. However, these methods have often failed the physician, and so the search continues for better ways to control the human heart rate.

In 1863 von Bezold[1] clarified especially the control of the heart rate by the vagus nerve. Hunt[2] observed in 1899 that the loss of vagus tone caused an acceleration of heart rate by shortening the diastolic period. It was the conclusion of Krogh and Lindhard[3] in 1913 that the initial acceleration of the pulse in voluntary movement is the result of an outflow of impulses from the cortical motor centers of the vagus. This was distinct from the stimulation of the accelerator nerves via the sympathetic that caused a shortening of systole as well as diastole.

Although Langley[4] in 1892 demonstrated that accelerator impulses to the heart leave the cord by the upper five pairs of anterior roots and their white rami, he erroneously concluded that all such impulses had to travel through the cervical cardiac nerves to reach the heart.

Physiologists did an enormous amount of work on the factors controlling the heart rate, but it was not until 1926 that Cannon and Linton and associates[5] demonstrated in animals that accessory cardiac accelerator fibers are carried to the heart in the twigs of the thoracic sympathetic nerves that lie below the eighth cervical and first dorsal ganglions or stellate ganglion. This important anatomic discovery was soon verified by Braeucker in Germany.[6] Ionesco, Enachescu and Teitel[7] stimulated the nerves from the second through the fifth thoracic sympathetic ganglions and observed acceleration of the heart rate. They also showed, contrary to the previous assumption, that removal of the stellate ganglions alone does not deprive the heart of its accelerators. In 1930 Kuntz and Morehouse[8] in this country showed clearly that cardioaccelerator nerves direct to the human heart come from the second, third, fourth and fifth thoracic ganglions of the sympathetic nervous system. These observations have recently been repeated by Saccomanno, Utterback and Klemme[9] in dogs.

Until now there has been no adequate description of the effects on the human heart rate resulting from the operative removal of these thoracic sympathetic nerves (second to fifth dorsal). This closure of the gap between physiologic indications and application in practice has been dependent on the development of surgical technics of intrathoracic surgery that has come largely in the past decade.

As early as 1932 Leriche and Fontaine[10] mentioned ablation of the cervical-thoracic sympathetic chain but denied experience with this operation. In the discussion they mentioned that this operation had been suggested earlier by Franck but was considered dangerous by Danielopolu as it would sacrifice the vasomotor nerves and cardiac accelerators. Indeed, as recently as 1941 White[11] remarked that by total sympathectomy "the heart would undoubtedly be greatly crippled." However, in 1936, Brouha, Cannon and Dill[12] had shown that totally sympathectomized dogs run, jump, play and look like normal dogs and yet after exercise their pulse rates are 30 to 40 per cent below those of normal dogs. By 1938 Smithwick[13] had done a total sympathectomy on a hypertensive man without ill effects and noted that bradycardia was present. In 1944 Grimson,[14] in reporting bilateral sympathectomy on human beings, mentioned no ill effects on cardiac function. Adson and Brown[15] reported that they had not observed any diminution of pulse accel-

eration after effort when the first two or three thoracic ganglions had been severed.

The idea leading to our present observations came from patients who had thoracic sympathetic nerves severed and later noted that their pulse rate was slower and that exercise did not cause as great an increase in heart rate as before operation.

CLINICAL MATERIAL

GROUP I

The first group consists of 7 patients, none of whom had heart disease or during our observation were given drugs such as digitalis. In the first 2 with Raynaud's syndrome, precordial pain and tachycardia, the removal of the thoracic sympathetic ganglions from the second to the fifth dorsal, first on the left side and later the right side, was done. The decrease in pulse rate was most notable after the second or right side had been operated on. These 2 cases support the anatomic and physiologic observations that cardioaccelerator fibers are contained chiefly in the second through the fifth thoracic sympathetic ganglions.

However, in the third case, that of a girl aged 15 with hyperhidrosis, only the second and third dorsal ganglions were decentralized, and yet a decided diminution in pulse rate was observed by the patient and our step tests indicated a diminished acceleration to exercise. The fourth patient, a woman of 56 with Raynaud's disease, had a similar operation (the second and third dorsal ganglions removed from both sides) and yet like others experienced little or no change in the pulse rate.

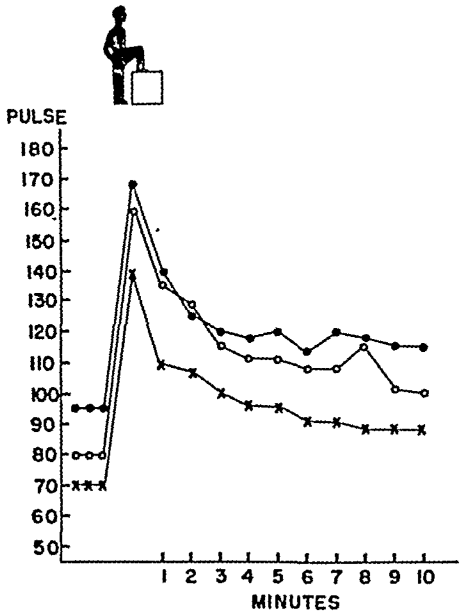

Chart 1.—Pulse response of patient T. E. to step test. Line with solid circles, response before thoracic sympathectomy. Line with open circles, response two months after left sympathectomy (second through fifth dorsal ganglion). Line with crosses, response two months and twenty months after right sympathectomy (second through fifth dorsal ganglions).

The last 3 patients had what we term "sympathetic syndromes"—headache, precordial pain, tachycardia and hyperhidrosis, and had long been suspected to have heart disease and hyperthyroidism, although we could find no evidence of these disorders. The upper five thoracic ganglions were disconnected on the left side of these 3 patients, and all experienced a relief of pain and 2 had relief of tachycardia, both symptomatically and by test.

Case 1.—T. E., a butcher aged 34 years, had Raynaud's syndrome, headaches, slight hypertension and rapid heart action. June 8, 1944, he had a left thoracic sympathectomy (the second, third, fourth and fifth dorsal ganglions), and after this had clinical improvement and less pulse acceleration to the exercise test. March 1, 1945, he had a right thoracic sympathectomy (second, third, fourth and fifth dorsal ganglions). The subsequent course showed the patient asymptomatic and a normal pulse response to the exercise test.

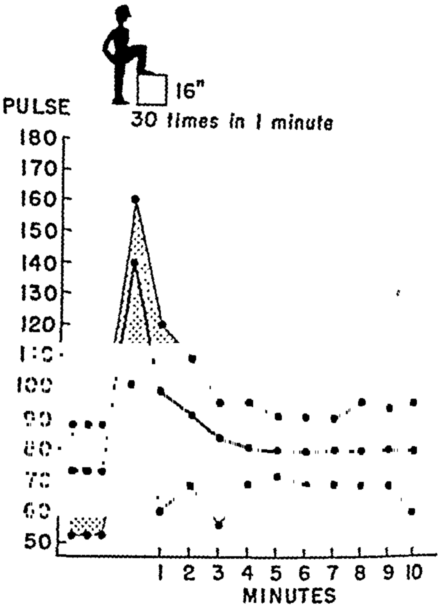

Chart 2.—Normal response to step test.

This patient entered the Baker Memorial Hospital in June 1944, complaining of cold hands and feet for as long as he could remember. In addition, he had known of a high blood pressure and a rapid heart action for several years. An intravenous pyelogram in 1942 was normal. Headaches had troubled him for years. He appeared healthy; the hands were cold and pale; the heart was regular and rapid, and both low and high-pitched systolic murmurs were heard at the apex. The blood pressure was 160 systolic and 88 diastolic. A roentgenogram showed the heart to be normal in size and configuration. The electrocardiogram showed regular rhythm, P waves and P-R interval normal, QRS complexes normal; the T waves were upright 3 mm. in lead 1, 4 mm. in lead 2 and 9 mm. in lead 4.

In the hospital a 16 inch (41 cm.) exercise test was done showing a rapid heart rate that returned to only 116 in ten minutes.

June 8, 1944, a left thoracic sympathectomy was done to relieve his cold hand and to see whether this procedure would slow the pulse or prevent it from accelerating in response to exercise. At operation the second and third sympathetic ganglions were decentralized and encased in a silk cylinder. The fourth and fifth ganglions were removed through the resected fifth rib. Also the second and third intercostal nerves were resected, dividing the roots proximal to the posterior root ganglions.

By June 14 the pulse rate was slower and observers were surprised by the disappearance of his murmurs. His recovery was uneventful, and he left the hospital June 15. August 4 exercise tests showed less acceleration and a decrease to a rate of 100 after ten minutes.

Feb. 26, 1945, he returned to the hospital saying that the left hand had been warm and dry since operation; the right hand still pained on exposure to cold. He was still troubled with palpitation and occasional throbbing headaches, although the latter were less severe since the operation. The examination now showed a slower heart, blood pressure of 150 systolic and 84 diastolic, and a high-pitched systolic murmur could be heard only on inspiration at the left lower sternal border. Because of these symptoms a similar operation was done March 1, and the right second, third, fourth and fifth sympathetic ganglions were disconnected. Recovery was uneventful. On May 18 he reported that he was feeling fine, and the exercise test showed a rise of the pulse rate to 120 and rapid fall to 80. He continued well and on March 16, 1946, a cold postural test of blood pressure was done. His average lying blood pressure was 151 systolic and 66 diastolic and average standing pressure was 147 systolic and 88 diastolic. On cold stimulation he was a normal reactor. The pulse rate averaged 60. He no longer noted headaches, palpitation or cold hands.

May 8, 1946, and Nov. 27, 1946, he was again examined and found fit. He had no complaints, and his resting pulse rate was 60 and blood pressure was 145 systolic and 82 diastolic. His basal metabolic rate was minus 9.

Case 2.—A. M., a nurse aged 41, had attacks of precordial pain, tachycardia and dyspnea. On May 21, 1946, a left thoracic sympathectomy was done (second to fifth dorsal ganglions) followed by decrease in pulse rate and freedom from pain. A right thoracic sympathectomy (second to fifth dorsal ganglions) was done Feb. 3, 1947, and immediately after operation her pulse rate was 48. Her convalescence was uneventful, and two months later the step tests showed a pronounced decrease in pulse acceleration to exercise; she stood the exercise well.

Case 3.—A. P., a school girl, aged 15, had hyperhidrosis. In February 1944, in a bilateral thoracic sympathectomy the second and third ganglions were resected. Her hands have remained dry and warm. The resting pulse rate is slower, and there is less acceleration of rate during exertion.

Case 4.—G. J., a woman aged 56, had Raynaud's syndrome since 1923. March 7, 1947, the right second and third thoracic sympathetic ganglions were resected; March 19 similar ganglions on the left were removed. Recovery was uneventful, and yet her pulse response to the exercise test was the same before and after operation.

Case 5.—H. H., a woman aged 33, had precordial pain, tachycardia, pains in the left arm and hyperhidrosis. She was suspected to have heart disease. Sept. 21, 1945, the thoracic ganglions 1 through 6 were removed. The patient experienced pronounced relief of symptoms and gained 18 pounds (8.2 Kg.). The pulse rate was slower and there was less acceleration to exercise. The symptoms returned in the spring of 1947, and vasomotor tests indicated regeneration of the sympathetic fibers.

Case 6.—K. L., a woman aged 31, had precordial pain, hyperhidrosis, tachycardia and pounding headaches for three years. There was no proof of heart disease. Operations on the breast did not afford relief. July 3, 1945, a left thoracic sympathectomy (second to fifth dorsal ganglions) was done, followed by relief of symptoms and a slower pulse rate. Pain returned in the left costal margin area in the spring of 1947.

Case 7.—C. G., a housewife aged 37, had precordial pain and tachycardia of nine years duration. Jan. 29, 1946, a left transthoracic sympathectomy was done (second to sixth dorsal ganglions inclusive). Subsequently there was relief from pain but slight decrease in pulse rate.

GROUP II

The second group consists of 2 patients who had angina pectoris, 1 also having paroxysmal tachycardia. Both showed a pronounced slowing of the heart rate after both left and right dorsal sympathetic ganglions had been removed. However, in both there was little if any change in the heart rate after the first operation or removal of the first to the sixth dorsal ganglion on the right side and the first to the ninth on the left side.

Case 8.—V. R., a man aged 30 years, had rheumatic heart disease, aortic regurgitation, paroxysmal tachycardia and angina pectoris. Cardiac denervation was done by transthoracic maneuver On March 14, 1947 a left transthoracic sympathectomy was done from the first through the sixth dorsal ganglion, inclusive (Horner's syndrome). A right transthoracic sympathectomy was done on April 8, 1947 from the first through the sixth dorsal ganglion inclusive (no Horner's syndrome). The operation was followed by pronounced slowing of the pulse rate. No paroxysmal attacks of tachycardia have occurred following the operation (five months' follow-up). Angina pectoris is less frequent but not entirely relieved.

Case 9.—M. F., a woman aged 42 years, had angina pectoris, hyper-reactive blood pressure and sinoauricular tachycardia. On Aug. 15, 1946 a left transthoracic sympathectomy was performed from the first through the eighth dorsal ganglion. The top few centimeters of the great splanchnic nerve were removed. A right transthoracic sympathectomy was done on Sept. 4, 1946 from the first through the ninth dorsal ganglion (bilateral Horner's syndrome). There was definite relief of symptoms with slowing of pulse rate and less acceleration to exercise. The patient has experienced no attacks of angina since the operation, although her electrocardiogram remains abnormal.

GROUP III

The third group consists of 4 hypertensive patients who had splanchnic denervations prior to having cardiac denervations. Two of these had Peet operations (the ninth through the twelfth dorsal ganglion) several years before cardiac denervation; 1 of these then had right dorsal sympathectomy (the first through the tenth dorsal ganglion), and two weeks later the left side was done. The other had the left side done first and then the right. Both showed a lowering of the resting pulse rate and a diminished response to the exercise test[16] that was established chiefly after both sides had been operated on.

Case 10.—A. S., a woman aged 44 years had a sympathectomy (Peet maneuver) five years before admission. She had hypertension, type 2[17] with a test range of 197 to 230 systolic and 128 to 160 diastolic. Her heart showed left ventricular enlargement by roentgen rays. Her fundi were grade 2.[17] On April 3, 1947 a right transthoracic sympathectomy was performed from the first through the tenth dorsal ganglion (no Horner's syndrome). A left transthoracic sympathectomy was done on April 18, 1947 from the first to the tenth dorsal ganglion inclusive. This extended down to dural clips of the previous procedure (left Horner's syndrome). There was pronounced decrease in pulse rate and decreased pulse rate response following operation. Immediate relief of angina and headaches were noted, and there was some immediate lowering of blood pressure. Further follow-up will be necessary for evaluation of the latter.

Case 11.—C. C., a man aged 26 years, had had hypertension since the age of 15 years. On physical examination the heart was normal and the fundi were normal. The electrocardiogram was within normal range, renal function normal and blood pressure type 2. On June 9, 1943 a right lumbodorsal splanchnicectomy was performed from the ninth through the twelfth dorsal ganglion. A left lumbodorsal splanchnicectomy was done on June 22, 1943 from the ninth through the twelfth dorsal ganglion. At entry in the hospital in April, 1947, his blood pressure was type 1, as indicated by postural and cold test with test range 134 systolic and 106 diastolic to 176 systolic and 150 diastolic. The fundi showed grade 2 changes. The electrocardiogram was normal. The renal function and heart function were normal. On April 23, 1947 a left transthoracic sympathectomy was performed from the second to the seventh dorsal ganglion. A right transthoracic sympathectomy was done on May 2, 1947 from the first to the eighth dorsal ganglion. There was definite slowing of heart rate and definitely decreased response to exercise immediately following operation.

The other 2 patients in this group had more extensive previous lumbodorsal sympathectomies. One then had the first through the sixth dorsal ganglion removed on the right followed by removal of the first through the seventh on the left; the other had the first through the seventh removed first on the left and later on the right side. Both showed a pronounced decrease in the resting heart rate and a pronounced diminution in acceleration to the exercise test after the second operation.

Case 12.—H. R., a man aged 41 years, had hypertension of seven years duration. In March 1944, blood pressure was decidedly elevated (postural and cold test gave test range 232 systolic and 154 diastolic to 174 systolic and 114 diastolic type 2 pressure). Fundi showed grade 3 changes. An electrocardiogram showed inverted T waves in leads 1 and CF5 and low T2. Renal function and heart function were normal. Right lumbodorsal splanchnicectomy was done on March 7, 1944 from the eighth dorsal through the second lumbar ganglion inclusive. On March 29, 1944, a left lumbodorsal splanchnicectomy was done from the eighth dorsal through the first lumbar ganglion inclusive. After this operation the patient had good symptomatic improvement. The electrocardiogram returned to normal, and there was a fairly good blood pressure response until about four months before the last admission, at which time the blood pressure became greatly increased again and the patient became heart conscious with tightness in substernal area and palpitation. Electrocardiographic changes were consistent with hypertensive heart disease and similar to those noted prior to lumbodorsal splanchnicectomy. On March 8, 1947, a right transthoracic sympathectomy was done from the first through the sixth dorsal ganglion inclusive. On March 21, 1947 a left transthoracic sympathectomy was performed from the first through the seventh dorsal ganglion inclusive (bilateral Horner's syndrome) There was a definite decrease in pulse rate following bilateral transthoracic sympathectomy with decreased response to exercise but practically no change after the first operation or the right transthoracic sympathectomy was done. There was a reversal of the electrocardiogram to normal immediately after transthoracic sympathectomy with disappearance of heart consciousness. Five months after transthoracic sympathectomy, basal pulse rates and pulse rate response remained about the same as immediately after the operation The blood pressure had returned to levels similar to those previous to operation and likewise the electrocardiogram had become abnormal as previously noted. At this time, the patient was placed on a modified rice diet with excellent response. Not only was the blood pressure greatly reduced, but the electrocardiogram reverted toward normal once again.

---

[16] Unlike group I the patients in groups II, III and IV were judged unable to perform a test as vigorous as the step test. Hence in these latter groups the "two step exercise test" of Master was used. (Master, A. M.; Nuzie, S.; Brown, R. C., and Parker, R. C.: The Electrocardiogram and the "Two-Step" Exercise, Am. J. M. Sc. 207:435 [April] 1944).

[17] Smithwick, R. H.: Surgical Treatment of Hypertension: The Effect of Radical (Lumbodorsal) Splanchnicectomy on the Hypertensive State of One Hundred and Fifty-six Patients Followed One to Five Years, Arch. Surg. 49:180 (Sept.) 1944.

Case 13.—V. T., a woman aged 48 years, had long-standing hypertension. In 1941 she had a coronary thrombosis In 1945 a lumbodorsal splanchnicectomy was performed; left, the eighth dorsal through the second lumbar ganglion; right, the seventh dorsal through the first lumbar ganglion After lumbodorsal splanchnicectomy, she felt much better in some respects, but palpitation and tachycardia became a major problem. The latter was associated with angia. Palpitation and rapid heart rate were considerably more pronounced than are usually noted after lumbodorsal splanchnicectomy. The patient was readmitted to the hospital because of these complaints On physical examination the patient looked well; the heart showed no change except tachycardia. The electrocardiogram showed changes consistent with coronary heart disease. Renal function was normal. The fundi showed grade 1 changes. On Jan. 17, 1947 a left transthoracic sympathectomy was done from the first through the seventh dorsal ganglion. On Feb. 4, 1947 a right transthoracic sympathectomy was done from the first through the seventh dorsal ganglion (bilateral Horner's syndrome). There was considerable slowing of heart rate following left thoracic and pronounced slowing following the bilateral procedure. The patient has been entirely relieved of tachycardia, but she continues to have symptoms brought about by postoperative hypotension as well as some pain in the chest.

GROUP IV

The fourth group consists of 6 patients with hypertension who had a total thoracic sympathectomy. Four of these 6 were operated on for relief of their angina pectoris as well as to lower their blood pressure. The other 2 were operated on in hope of relieving them of their persistent sinus tachycardia as well as to lower their blood pressure. In all 6 after bilateral thoracic sympathectomy there was a definite decrease in the resting heart rate and a diminished heart rate response to the exercise test.

Case 14.—B. P., a man aged 56 years, had had known hypertension since 1942. Symptoms began six months before admission, the outstanding being substernal oppression and discomfort along the left sternal border which was brought on by exercise, eating and emotional stimulation and which was relieved by rest and glyceryl trinitrate. On physical examination the heart was normal. Blood pressure was type 2 (postural and cold test range being 158 systolic and 106 diastolic to 222 systolic and 170 diastolic). Renal function was normal. The fundi were grade 1 The electrocardiogram showed changes characteristic of hypertensive heart disease. A left transthoracic sympathectomy was performed on Oct. 7, 1946 from the first through the eleventh dorsal ganglion. The great splanchnic nerve was removed from its origin down to the diaphragm. On Oct. 22, 1946 a right transthoracic sympathectomy was performed from the first through the twelfth dorsal ganglion. The great splanchnic nerve was removed from its origin to the celiac ganglion. Horner's syndrome developed only on the right. There was moderate lowering of pulse rate and decidedly decreased response to exercise. Angina was completely relieved immediately after the operation, and the electrocardiogram returned toward normal, although it was not entirely normal three months after the operation. One year after the operation, the basal pulse rate was definitely decreased with decreased pulse rate response. The angina was entirely relieved, with a normal electrocardiogram.

Case 15.—H. L., a man aged 53 years, was known to have had elevated blood pressure for twenty-five years. In 1945 angina pectoris developed which became progressively worse, and he had an occasional attack of angina decubitus; both were relieved by glyceryl trinitrate. There was a strong family history of cardiovascular disease On physical examination, the heart showed no enlargement but the rate was rapid and there was a faint gallop at apex; there was no other evidence of congestive failure The blood pressure was type 2 (test range being 188 systolic and 123 diastolic to 210 systolic and 140 diastolic). Renal function was normal. The electrocardiogram showed changes consistent with coronary and hypertensive heart disease. A right transthoracic sympathectomy was done Oct. 24, 1946 from the first to the twelfth dorsal ganglion inclusive. A left transthoracic sympathectomy was done Nov. 13, 1946 from the first to the eleventh dorsal ganglion (bilateral Horner's syndrome) There was some slowing of the pulse rate following the right total thoracic sympathectomy but decided slowing of pulse rate following the bilateral total thoracic sympathectomy. There was complete relief of angina immediately after the operation, and definite improvement in the electrocardiogram.

Case 16.—H. H., a man aged 45 years, had had elevated blood pressure since 1942. His symptoms consisted chiefly of angina pectoris, headaches, fatigue and increased nervousness which first began in 1945. On physical examination the patient looked well. Fundi showed grade 1 (minimal) changes. No enlargement of heart was evident by roentgen rays but the electrocardiogram was consistent with coronary heart disease. The blood pressure was type 2 (test range 132 systolic and 88 diastolic to 168 systolic and 120 diastolic). Renal function was good. On April 3, 1947 a left transthoracic sympathectomy was performed from the first through the twelfth dorsal ganglion. A right transthoracic sympathectomy was done on April 30, 1947 from the first through the twelfth dorsal ganglion. There was moderate slowing of pulse rate following the left thoracic sympathectomy and decided slowing with decreased response to exercise following bilateral thoracic sympathectomy. Complete relief of angina followed the operation, with a normal electrocardiogram.

Case 17.—G. R., a woman aged 45 years, had had elevated blood pressure since 1932. Physical examination showed an overweight woman who appeared nervous and who had several attacks of pain during the course of her examination and during the exercise test. The heart was enlarged to the left. The blood pressure was type 2 (test range being 172 systolic and 115 diastolic to 232 systolic and 160 diastolic. The eyes showed hemorrhages in the fundi (grade 3). Renal function was good. Electrocardiographic changes were consistent with hypertensive and coronary heart disease. A right transthoracic sympathectomy was done on Feb. 24, 1947 from the first to the tenth dorsal ganglion and a left transthoracic sympathectomy was done on March 15, 1947 from the first to the eleventh dorsal ganglion. There was decided slowing of pulse rate with decreased acceleration to exercise following the operation. There was immediate relief of angina pectoris with moderate lowering of blood pressure immediately following operation. The electrocardiogram remained abnormal.

There was some effect in 4 patients after unilateral sympathetic denervation. Analysis of these 4 cases is also of particular interest in trying to determine which side exerts a dominant influence on the heart rate. Of 2 who had the first to the eleventh dorsal ganglion removed from the left side first, 1 showed a decrease in the heart rate while the other showed a temporary acceleration. Of the other 2 who had a similar operation done on the right side first, there was a similar response.

In the last 2 patients with hypertension and tachycardia but without electrocardiographic evidence of coronary heart disease there was a pronounced diminution in the resting pulse rate and response to exercise after the right dorsal sympathetics were removed. There was some additional effect after the second or left side was operated on.

Case 18.—R. C., a woman aged 48 years, was known to have had elevated blood pressure since 1939. Symptoms began at the same time, being chiefly fatigue, palpitation and occasional substernal oppression. There was no dyspnea, headaches or indigestion. Physical examination showed a patient who looked well. Blood pressure was of type 1, the blood pressure range being 196 systolic and 140 diastolic to 250 systolic and 168 diastolic; the fundi were grade 1; the electocardiogram was normal with exception of sinoauricular tachycardia, the rate being 126 per minute. Renal function and heart function were normal. Right transthoracic sympathectomy was performed on April 25, 1947 from the second through the twelfth dorsal ganglion. Left transthoracic sympathectomy was performed on May 15, 1947 from the second through the twelfth dorsal ganglion. There was pronounced lowering of pulse rate following right thoracic sympathectomy and some additional lowering following left thoracic sympathectomy, with decreased acceleration to exercise.

Case 19.—E. D., a woman aged 48 years, was known to have had elevated blood pressure since 1945; symptoms became troublesome at about the same time and consisted chiefly of heart consciousness, headaches, nervousness and fatigue. There was no angina but palpitation was pronounced when the patient was emotionally stimulated and after exercise. The past history was noncontributory. Results of the physical examination were as follows: The blood pressure was type 3 as indicated by the cold and postural test; test range, 188 systolic and 114 diastolic to 250 systolic and 160 diastolic. The electrocardiogram was normal with the exception of sinoauricular tachycardia; rate, 110. Renal function and heart function were normal The fundi were grade 2. Right transthoracic sympathectomy was performed on April 7, 1947 from the second through the twelfth dorsal ganglion. Left transthoracic sympathectomy was performed on April 28, 1947 from the second through the twelfth dorsal ganglion. There was pronounced slowing of pulse rate after the right thoracic sympathectomy with decreased response to exercise. Practically no additional slowing followed the left thoracic sympathectomy.

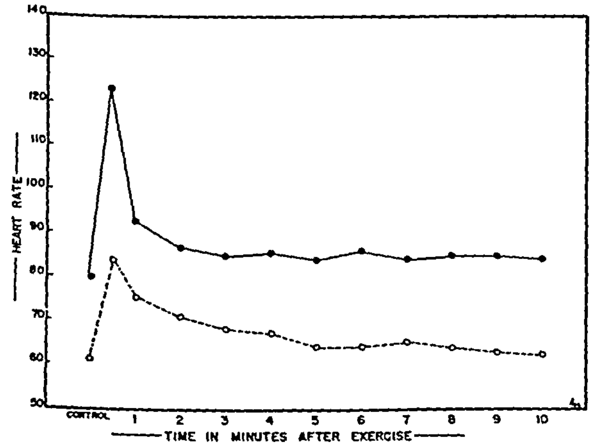

Chart 3.—Exercise tests before (solid line) and after (dotted line) cardiac denervation in 11 patients from groups II III and IV.

SUMMARY

Removal of the thoracic sympathetic ganglions from the second to the fifth dorsal inclusive on the left or right side usually causes some slowing of the basal pulse rate and a diminished pulse response to exercise. Removal of these ganglions from both sides invariably has had the greatest effect on heart rate. The cardiac innervation from the right thoracic sympathetic chain may exert a greater influence on heart rate than that from the left side in some persons, but the origin and course of cardioaccelerator fibers are variable. This variation between the two sides and from person to person is a known characteristic of the sympathetic nervous system.

The evidence so far indicates that in patients who have had more extensive resections of the sympathetic ganglions the effect on the pulse rate has been no greater than in those in whom only the second to the fifth dorsal ganglions inclusive were removed bilaterally. In fact, the effect of sympathectomy on heart rate was no greater in those patients who had splanchnic denervation, supposedly including the adrenals, than in those who had cardiac (second to fifth dorsal ganglion) denervation only.

CONCLUSIONS

Motor pathways (cardioaccelerator fibers) to the human heart appear to be derived from both the right and left second, third, fourth and fifth thoracic sympathetic ganglions. When these ganglions are removed, there is a pronounced reduction in basal pulse rate as well as a diminished acceleration following exercise.

These preliminary observations suggest that this procedure may be of therapeutic value in the control of tachycardia and possibly other disturbances of cardiac rhythm in selected patients.

ABSTRACT OF DISCUSSION

Dr. Keith S. Grimson, Durham, N. C.: It is not possible for me to discuss the treatment of tachycardia and of anginal pain or the justification of sympathectomy since my associates and I have not yet elected surgical treatment and do not favor alcohol block. It is possible, however, to speak of the effects of sympathetic denervation of the heart in 77 patients with hypertension treated during the last seven years by transthoracic subtotal to total sympathectomy. There is debate in the literature that sympathetic denervation of the heart might be good or bad for the coronary circulation in man and that bradycardia might aid or harm cardiac function. The denervation includes both the cardiopulmonary and the splanchnicadrenal-renal area. This operation is always followed by bradycardia and lessened acceleration during exercise of standing, particularly when vasoconstriction remains in the feet. This operation differs decidedly from the Smithwick operation for hypertension, which denervates only the splanchnic area and the lower half of the body and leaves compensatory postural and exercise tachycardia. Dr. Wright Adams ran master step exercise tests on my patients before and after subtotal to total transthoracic sympathectomy. Reduction of blood pressure and of pulse rate occurs, and after operation the recovery trend of blood pressure is up rather than down. Cardiac output in the supine position is reduced, as it is in normal dogs after total sympathectomy. The survival rate of these patients, in spite of an initial serious hypertensive disease process, has convinced us that sympathetic denervation of the coronary arteries and bradycardia is not harmful. Only 9 patients have died since operation. I can therefore approve of the studies presented by Dr. Chapman.

Dr. C. Heymans, Ghent, Belgium: Series of experiments have been performed in our laboratory on dogs, cats and monkeys concerning the effects of the sympathetic and parasympathetic (vagus) on the heart rate. These experiments showed that the increase of heart rate during muscular exercise is principally due to a reduction of the vagal cardioinhibitory tone, to a slight increase of the sympathetic cardioacceleratory tone and to an increase of secretion of epinephrine. In dogs in which complete sympathectomy has recently been done the heart rate only increases up to the automatic rate during exercise. After some weeks, the heart rate of these dogs increases, however, above the automatic rate during muscular exercise, probably by the action of cardioaccelerator fibers present in the vagus. The general behavior and the capacity to stand intense muscular exercise remain normal in dogs whose sympathetic chains have been completely removed. These observations have been confirmed by L. Brouha, W. B. Cannon and D. B. Dill (*J. Physiol.* **87**:345, 1936). I should like to ask Dr. Chapman whether cardioaccelerator fibers coming from the brain and going to the heart through the vagus may also not be partly responsible for the increase of heart rate during muscular exercise in human beings on whom sympathectomy has been done.

DR. EARLE M. CHAPMAN, Boston: I want to thank Dr. Grimson for discussing his experience, which I believe corroborates ours, and then to say in reply to Dr. Heymans that it is gratifying that our observations came from patients who first were operated on for other reasons than to slow the heart. It was their own observations that stimulated us to consider this and go further with it. His observation of the fact that accessory fibers are carried down the vagi in the dog might be true in human beings, but we have no evidence as yet that points that way. We thought the variation in these persons from side to side indicates that even the normal pattern of anatomy of the sympathetic nervous system is a variable and diffuse one. Nature perhaps seeks many pathways in seeing that it gets its accelerator fibers to the heart. Another characteristic of the sympathetic is regeneration and the attempts to overcome these operative procedures. I might tell you about the first patient that was operated on 1942. He had no angina and no discomfort until April of this year, and he then returned and said that his left hand was becoming white again and his pain was returning, so that this procedure is still in the experimental stage and we see here five years later that nature has finally overcome us and sent fibers back through again. Total thoracic sympathectomy causes a fall in the blood pressure, as one expects with this operation, but the thing that one sees with low dorsal sympathectomy, which is an elevation of pulse rate, did not occur. In fact the fall in pulse rate is similar to that after severing only the ganglions from the second dorsal through the fifth dorsal. A nonhypertensive person had a pulse consistently in the upper forties after this upper dorsal sympathectomy, and some concern was felt because of her slow heart, but she has functioned well and has had no discomfort, and her electrocardiograms continue to be normal and she has resumed her activity, with pulse rates now in the sixties.

PERIPHERAL VASCULAR DISEASE IN THE LUNGS

Roentgenologic Manifestations

ROBERT P. BARDEN, M. D. and DAVID A. COOPER, M. D.
Philadelphia

Although there has been extensive study of the changes in the peripheral vessels of the systemic circulation when affected by disease either primarily or secondarily, medical literature contains relatively few references to diseases of the peripheral pulmonary vessels. By roentgenologic examination, there is available a window through which one may view the pulmonary circulation in a manner which cannot be utilized in the study of the blood vessels of the rest of the body. It would seem useful, then, to review our knowledge of the conditions which may affect the small vessels of the lung and examine the pathologic and roentgenologic manifestations of them.

In an excellent series of monographs, Brenner[1] has indicated that the arterioles, capillaries and venules of the lung may be subject to degenerative, infectious and neoplastic diseases similar to those encountered in the peripheral vessels of the systemic circulation, but accompanied by entirely dissimilar clinical states (the table). Furthermore, because of the anatomic relation of the lung to the rest of the circulation, it receives in the sieve of its peripheral vessels emboli from a great variety of diseases, many of which become manifest for the first time only after the pulmonary complications.

*Pathologic Classification of Diseases of Pulmonary Arterioles and Capillaries**

1. Sclerosis.
2. Endothelial proliferation.
3. Infections, acute and chronic.
4. Neoplasm.
5. Thrombosis
6. Allergy.
7. Increased permeability.

* Modified, after Brenner.[1] This is a classification, by pathology, of the material discussed in this paper. A great variety of clinical conditions may be included under these few pathologic headings.

To these general divisions in pathology may be added another, of more recent conception, that of the effects of hypersensitivity states on the pulmonary vessels. Alterations in the tone of the small vessels of the lung occur in many allergic states in which the vessels act as the sensitized shock organs.[2] In addition there is a group of diseases in which arteriole and capillary permeability is altered, throughout the body, and this abnormal state may be reflected in changes in the lung recorded by roentgenologic examination.[3]

For practical purposes of clinical diagnosis, peripheral vascular disease of the lung may be considered under three headings: intrinsic disease of the vessel wall or obstruction of the lumen; changes in vessels produced by adjacent disease of the pulmonary parenchyma, and toxic and hypersensitivity states resulting in increased permeability of vessel walls with or without demonstrable organic change in the vessel itself.

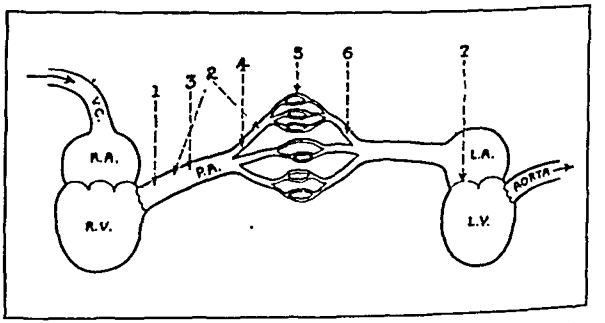

Fig. 1.—In this diagrammatic drawing of the pulmonary vascular system, the peripheral vessels are indicated by numbers 4, 5 and 6. Diseases and insults occurring in these locations form the material discussed in this paper. (The diagram demonstrates the locations of the most common causes of obstruction: 1, congenital heart disease; 2, pulmonary thrombosis, embolism; 3, pulmonary arterial disease; 4, pulmonary arteriolar disease; 5, reduction of capillary bed; 6, venous thrombosis, and 7, mitral stenosis.)

INTRINSIC DISEASE OF PULMONARY VESSELS

In considering intrinsic disease of the pulmonary

From the Department of Radiology and the Department of Medicine, Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania.

Read before the Section on Radiology at the Ninety-Sixth Annual Meeting of the American Medical Association, Atlantic City, N. J., June 12, 1947.

A.: The Roentgen Appearance of the Chest in Diseases Affecting the Peripheral Vascular System of the Lungs, Radiology, to be published.

vessels, arteriosclerosis, arteriolarsclerosis and pulmonary hypertension are conditions of interest on both pathologic and clinical grounds and because there is still controversy about their identity. Although it is well established that pathologic lesions of arteriosclerosis and obliterative arteriolarsclerosis are frequently found in the lungs, the exact relationship of these findings to pulmonary hypertension and to clinical states of pulmonary failure is not finally decided. While Brenner[1] expressed the opinion that clinical symptoms are rarely present when only these pathologic lesions are found, many others[4] have stated that pulmonary hypertension frequently exists in association with obliterative vascular disease and that pulmonary or cardiac failure commonly supervenes. The relationship of degenerative changes in small vessels to emphysema, on the one hand, and allergy, on the other, is also an interesting controversial point. It seems likely that as improved methods for measuring pulmonary blood pressure during life are developed, some of these points of difference between pathologists and clinicians may be resolved.

However, from the standpoint of the roentgenologic examination of the lungs, one may suspect obliterative vascular disease under certain conditions. First, it so regularly accompanies advanced degrees of pulmonary emphysema that it may be considered as a corollary to that roentgen diagnosis. Second, it should be suspected in patients without emphysema but with pronounced symptoms of pulmonary insufficiency, on the basis of the negative evidence of a roentgenogram showing little deviation from the normal. And third, when pulmonary hypertension from whatever cause has lasted sufficiently long, failure of the right side of the heart ensues with roentgen observations which may be bizarre (Figs. 2 and 3).

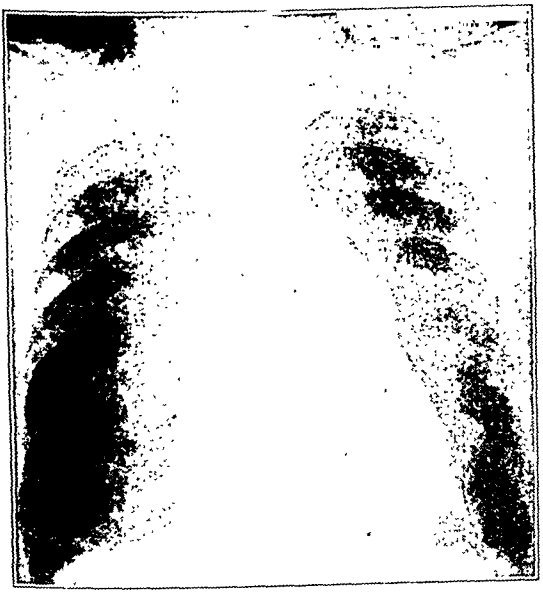

Fig. 2.—From a roentgenogram of the chest of a patient with increasing dyspnea and cyanosis of several years' duration. Because of increased pulsation of the large pulmonary vessels, observed fluoroscopically, and the peculiar cardiac silhouette, it was thought that congenital heart disease was present. Postmortem examination showed a cor pulmonale and no congenital lesion of the heart. There was advanced pulmonary emphysema and fibrosis with obliteration of the lumen of many of the arterioles. It was considered that the increased pulmonary pressure secondary to a decreased arterial bed had resulted in cardiac enlargement and failure.

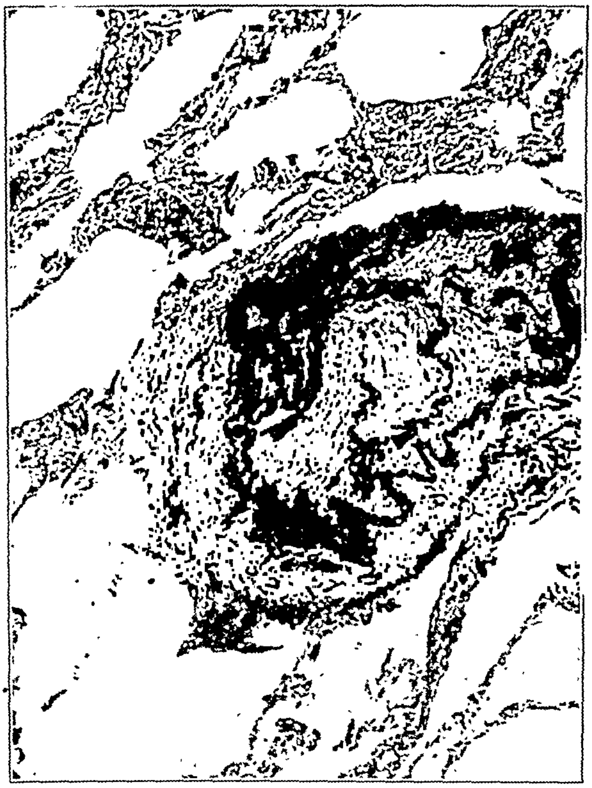

Fig. 3.—Photomicrograph of section of lung from a patient with a clinical history like that of the patient in figure 2, and showing extreme degrees of arteriolarsclerosis. Notice that the lumen of the arteriole in the center of the field has been reduced to a mere slit by the thickening of the intima.

Intrinsic disease which results in obstruction of vessel lumina by foreign material acting as emboli is usually recognized when large vessels are involved and infarcts ensue. However, the concept of bloodless infarcts which cast no roentgen shadow has been described by Westermark[5] and is not widely appreciated. Furthermore, when minute pulmonary blood vessels are obstructed by multiple emboli of whatever nature, the clinical and roentgenologic findings are often difficult to interpret. The predominant roentgen changes are usually exaggeration of the shadows cast by the peripheral vascular bed associated with irregular "beading" which may later become the picture of a diffuse, symmetric bronchopneumonia. Septic and organic and inorganic fragments circulating in the systemic blood vessels are commonly thought to account for the majority of pulmonary emboli.[4d] However, when one considers that pulmonary emboli are regularly associated with some neoplasms, such as carcinoma of the kidney, testis and liver, and may present as the first symptom of others, notably carcinoma and sarcoma of the stomach,[6] or that emboli and thromboses of pulmonary arterioles and capillaries may be expected at some stage of the disease in most leukemias and polycythemia vera, or that a great variety of parasitic infestations, such as malaria,[7]

schistosomiasis,[8] ascariasis, uncinariasis, and paragonimiasis [9] may affect the peripheral pulmonary vessels by embolism, it becomes clear that interpretation of these roentgenograms of the chest requires skill, experience and knowledge of all the diseases which must be included in the differential diagnosis (figs. 4 and 5).

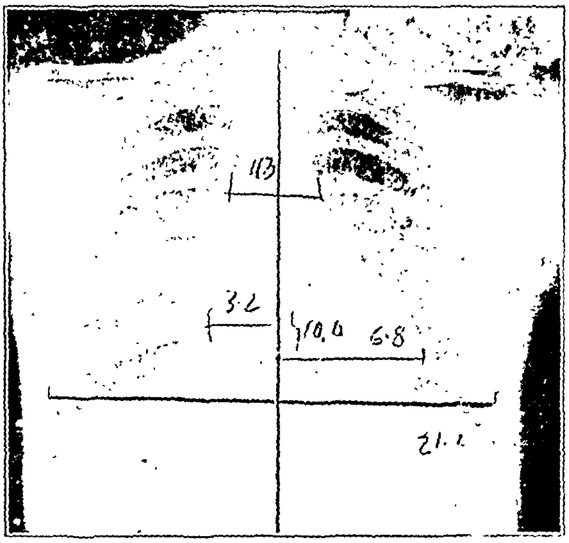

Fig. 4.—A girl aged 12, with cyanosis and dyspnea of four months' duration. She had a history of bathing in water infected with Schistosoma. The ova of this parasite were found in the feces, and the peripheral blood contained 35 per cent eosinophilic cells. Postmortem examination of the lungs in patients with this disease often reveals multiple capillary *emboli formed by ova circulating in the blood. In the roentgenogram* of the chest of this patient, one sees enlargement of the hilar shadows and increased prominence of the pulmonary markings with peripheral shadows in the lower lobes suggesting lobular atelectasis or confluent bronchopneumonia. (This illustration was furnished by Dr. Enrique Koppisch, School of Tropical Medicine, San Juan, Puerto Rico.)

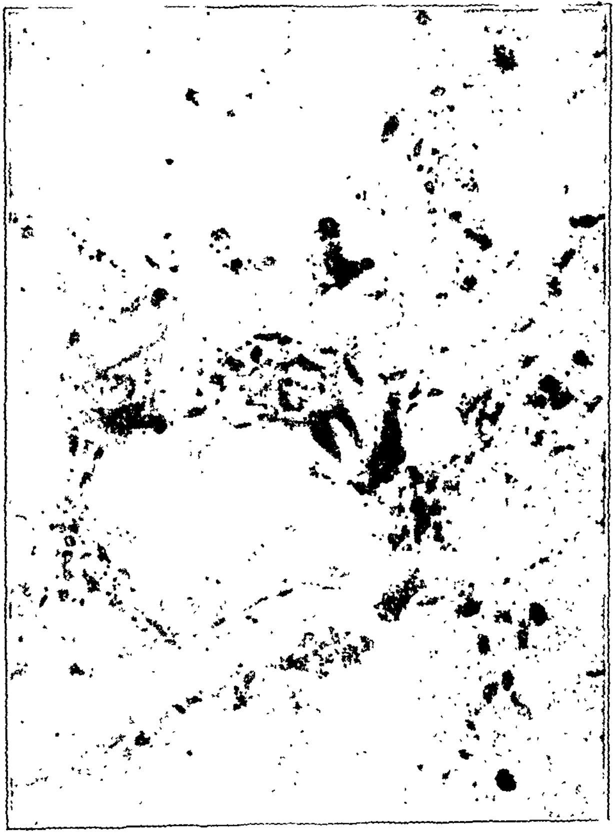

Fig. 5.—Photomicrograph of a section of lung from a patient with schistosomiasis. The dark irregular bodies in the center of the field are ova lodged in pulmonary capillaries. The inflammatory response is not pronounced. (This illustration was furnished by Dr. Enrique Koppisch.)

CHANGES IN VESSELS FROM ADJACENT DISEASE OF PULMONARY PARENCHYMA

The concept that primary diseases of the lung cause changes in and obliteration of adjacent blood vessels is not new. Nevertheless, it is useful to recall that delayed or abortive healing of many of these conditions is due to irreversible damage to the blood supply of the part of the lung involved, and not, as might appear to superficial analysis, to continuation of the disease process itself. A progressive obliterative endarteritis may

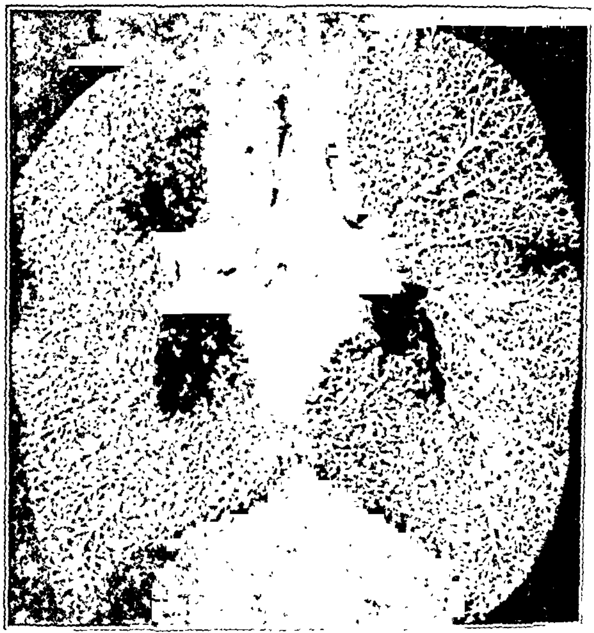

Fig. 6.—Specimen of an excised normal lung with radiopaque material injected into the vascular system. Notice the extensive ramifications of the vessels at the pleural edges. (After Birkelo and Brosius.[10])

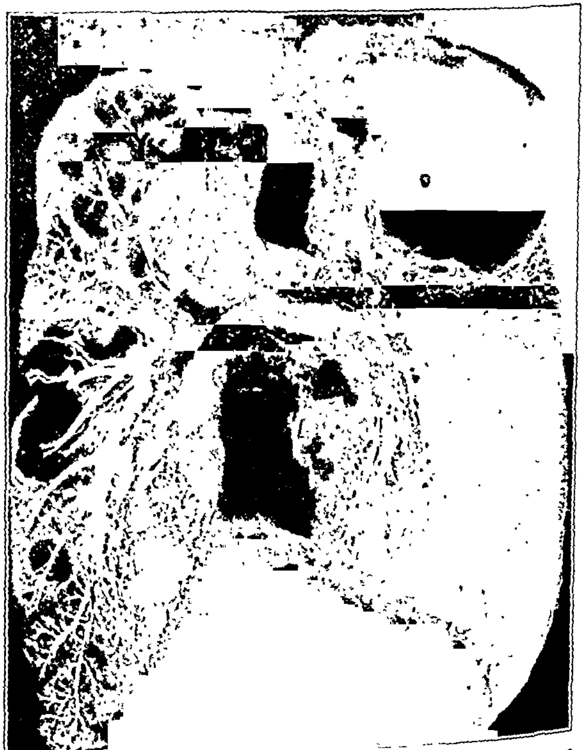

Fig. 7.—Radiopaque material has been injected into lungs from a patient with far advanced pulmonary tuberculosis. *Note the reduction* in the number of small vessels in the right lung in particular. (After Birkelo and Brosius.[10])

accompany acute pneumonias of any type and is always found in chronic inflammatory conditions and neoplasms of the lung. Progressive loss of blood supply is one of the fundamental pathologic changes accompanying chronic pulmonary tuberculosis[10] (figs. 6 and 7) and is also seen in silicosis with the development of large anemic infarcts, and this process is directly related to the impaired pulmonary function so regularly found in these conditions. The combination of restricted ventilatory capacity due to interstitial fibrosis and pleural thickening, and arterial disease, rapidly exhausts the reserve of the pulmonary system and produces pronounced symptoms of respiratory insufficiency.[4c] It is therefore important in evaluating the roentgenologic evidence of primary pulmonary disease to bear in mind the factor of peripheral vascular disturbance and its influence on pathogenesis, treatment and prognosis.

TOXIC AND HYPERSENSITIVITY STATES

The response of peripheral pulmonary vessels to a hypersensitivity state of the body as a whole is a nonspecific one, as Gregory and Rich have shown.[11] Reversible changes are found in some forms of bronchial asthma in which the pulmonary vessels act as shock organs.[12] As sensitization becomes more profound, organic destruction of the vessel walls occurs with necrosis. The pathologic lesion of blood vessels produced in this way has been found in experimental animals and man and is indistinguishable in a great variety of clinically and etiologically different conditions. It may be found in poisoning with sulfonamide compounds and serum sickness of all types and occurs as part of such generalized diseases as eczema, lupus erythematosus, acute rheumatic fever and periarteritis nodosa.[13]

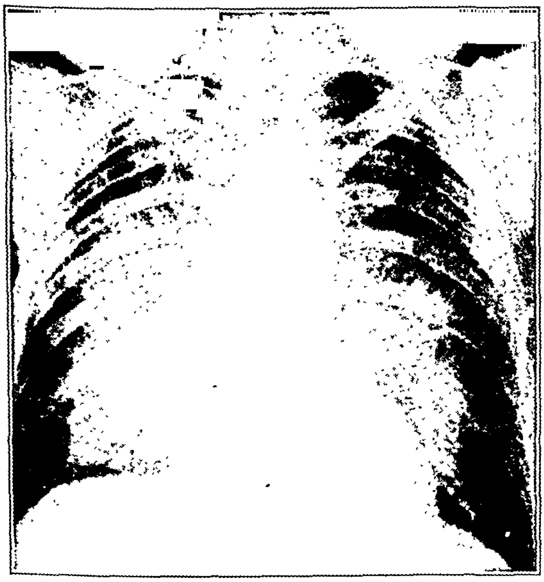

Fig. 8.—Roentgenogram of the chest of a patient with periarteritis nodosa, during an episode of acute pulmonary failure. Notice the position, rather symmetric distribution and fluffy character of the shadows. They may be evanescent, and disappear almost completely in twenty-four to forty-eight hours, as occurred in this patient.

The uniform response to such functional or organic impairment of the integrity of the vessel wall is its increased permeability to serum and plasma resulting in patchy or massive edema in the lungs and reflected by a characteristic shadow pattern on the roentgenogram of the chest (fig. 8).

The usual appearance is that of massive, fluffy shadows extending outward from each hilus in a symmetric fashion and occupying the inner two thirds of each pulmonary field. The periphery of these shadows blends imperceptibly with the adjacent aerated lung. In patients with less explosive symptoms the roentgen picture may be that of scattered subpleural shadows, again without definite margins and rapidly enlarging and merging together. Finally, in chronic or recurring subacute diseases, the appearance may be indistinguishable from bronchopneumonia.[11] The unusual features of the roentgen findings are the hilar or subpleural location of the shadows and the "cotton wool" appearance which they present. If healing occurs, as in some instances of acute rheumatic fever, pulmonary nodulation results, *and may be depicted by the roentgenogram (fig. 9).*

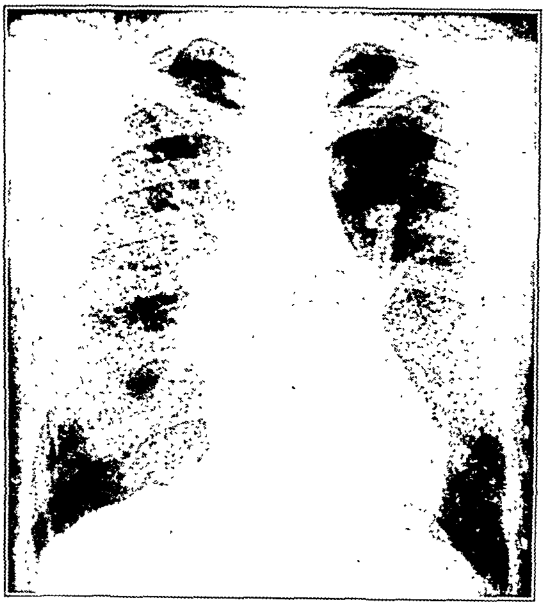

Fig. 9.—Roentgenogram of the chest of a patient who had recovered from acute fulminating rheumatic fever with pulmonary involvement. The fine, symmetric nodulation simulates silicosis. The appearance of the lungs has not changed during a twelve year follow-up period during which the patient has remained well. The pulmonary nodules are thought to be due to perivascular foci of connective tissue or deposits of hemosiderin.

The exact composition of these nodules is in dispute, some believing they are formed by perivascular connective tissue[15] and others stating that they represent deposits of hemosiderin remaining after resorption of extravasated red blood cells.[16]

The effects of exogenous or endogenous toxins on the walls of small vessels are identical in every way with the manifestations of hypersensitivity. Thus, pulmonary edema or hemorrhage follows such widely different conditions as the inhalation of irritating gases, epidemic influenza and glomerulonephritis in its terminal stages. In these three examples, increased permeability of peripheral vessels occurs as a result of the injury caused by *(a)* chemical, *(b)* bacterial and *(c)* metabolic poison.

To complete this review, it should be mentioned that changes on roentgenograms of the chest may be found in some deficiency states when vascular permeability is altered. This has been suggested as occurring in long-standing protein deficiency and beri-beri,[17] and more recently in a peculiar iron deficiency described by Waldenstrom.[18]

From the foregoing discussion, it is evident that specific roentgenographic changes cannot be expected in the many disease entities which involve the small vessels of the pulmonary system. However, in some of these conditions a shadow pattern characteristic of vascular damage may develop during roentgenologic study. If this evidence is properly evaluated, it may point the way to further investigation and clarification of an otherwise obscure disease, and thus render invaluable assistance to the patient.

SUMMARY

An attempt has been made to point out the roentgenologic manifestations of a great variety of diseases which affect the peripheral blood vessels of the lung and may produce changes in roentgenograms of the chest. These conditions include arteriolarsclerosis, emboli of all types, many primary pulmonary diseases and allergic and hypersensitivity states of the lung or the body as a whole.

ABSTRACT OF DISCUSSION

Dr. Francis M. Rackemann, Boston: I have a special interest in this paper, for it suggests an approach to an important problem. What happens when a man remains healthy up to the age of about 50 and then suddenly gets asthma which persists and may become severe? In order to answer that question one must know much more about the function of the lung. The symptom might depend on some lesion in the smaller bronchi or on a lesion in the alveolar membranes or in the lymphatics of the lung, but as Drs. Barden and Cooper point out, it is most likely that the lesions are located in the pulmonary blood vessels. The roentgenologists with whom I talk tell me that these diffuse shadows that one sees so often are of blood vessels much more than of the bronchi, even though one concedes that at the same time the bronchi are infected and that there is thickening of the bronchial wall. In ordinary cases the roentgenogram indicates pathologic changes that are gross, so that at autopsy one can see them without a microscope. It is hard to consider how the roentgenogram can show lesions which are microscopic, but this paper shows, again, that when microscopic lesions are grouped together a characteristic change occurs and that change is gross and therefore can be demonstrated by the roentgenogram. It is important to notice that the changes here are diffuse throughout both sides of the chest and therefore in great contrast to other lesions which are localized to one lung or, better still, to one area of one lung. Another thing that is important—and it is a good argument for the conception that these lesions are of vascular origin—is the fact that in the considerable variety of clinical states which Dr. Barden has described the roentgen lesions are much the same in each one of them. After all, is not that quite what it should be, if one assumes that the lesions depend on vascular disturbances which are scattered throughout the lung field? Are they not produced by a mechanism, the principle of which is common and the same in each case? This paper has given me much food for thought, and I am grateful accordingly to Drs. Barden and Cooper.

THE BONE BANK

LEONARD F. BUSH, M.D.
Danville, Pa.

and

C. ZENT GARBER, M.D.
New York

The necessity for additional bone for certain orthopedic operations has undoubtedly presented itself to surgeons many times. Secondary operations to obtain more bone are the result, thus prolonging the operative time, increasing morbidity and occasionally promoting a complicating factor. In certain patients, especially children, it may be difficult or impossible to obtain enough autogenous bone for the operation. Spinal fusions for scoliosis and disorders of the lower part of the back, the filling of large bone cysts and the replacement of defects in bone are a few of the common problems in which large quantities of bone are necessary. Macewen[1] in 1878 was the first to report the use of homogenous bone to rebuild a humerus. In recent years Ghormley[2], Inclan[3] and Smith[4] have reported the use of homogenous and syngenesious bone with good results. Inclan reported success in 24 of 34 cases with autogenous bone and in 6 of 8 cases with homogenous bone preserved in a refrigerator at plus 2 to plus 5 C. in saline solution, in saline solution and blood, or in citrate and blood. Smith in 2 cases kept bone in a refrigerator at approximately plus 4 C. and then autoclaved it just prior to use. In a hitherto unpublished case (Jan. 9, 1942) he employed bone refrigerated eighteen days without further treatment except washing in saline solution before using.

In 1945 the need for more bone became so apparent in patients suffering from severe scoliosis that Dr. William H. Von Lackum of the New York Orthopedic Hospital suggested a "bone bank." One of us (C.Z.G.) designed the bottles for storage. Excess bone which was formerly discarded in many operations was then placed in an ordinary refrigerator at plus 2 to plus 5 C., where it was kept for periods up to three weeks. The disadvantage of this method was that bone could be preserved for only a short period of time.

Read before the Section on Orthopedic Surgery at the Ninety-Sixth Annual Session of the American Medical Association, Atlantic City, N. J., June 13, 1947.

From the New York Orthopedic Hospital. Dr. Bush was formerly Annie C. Kane Fellow at New York Orthopedic Hospital. Dr. Garber is Pathologist, New York Orthopedic Hospital.

A review of the literature[5] gave some help on the problem of preservation of tissues but little regarding bone, especially for prolonged periods. We decided that if foods, serums and other perishable substances could be kept in a low temperature freezing cabinet, then perhaps this method could be used to preserve bone so that a constant supply would be available at all times. Experiments were undertaken to determine whether this was safe and what the tissue reactions would be to bone which had been preserved by freezing, whether autogenous or homogenous. The ilium, being cancellous bone and readily accessible, was considered as being suitable for studying osteogenesis and tissue reactions.

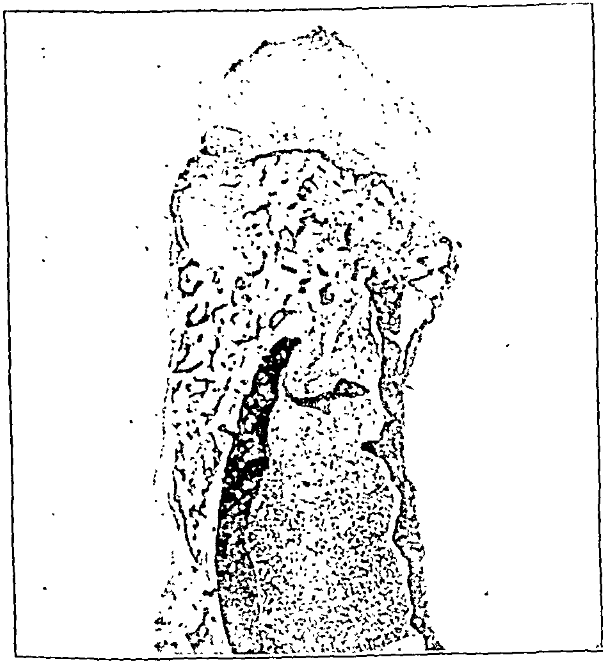

Figure 1.--Autogenous graft, fresh, 28 days in animal 107. Result was graded as "excellent."

Experimental Studies

Large chinchilla rabbits were used. Control studies were made with fresh autogenous and fresh homogenous grafts. Both iliac bones were used so that a parallel study could be made under the same conditions for both types of bone.

The next series of experiments dealt with bone which had been stored in a freezer at approximately minus 24 C. With the rabbit under pentobarbital sodium anesthesia, the bone was removed, placed in storage bottles and frozen for periods of one, two, four, eight and twelve weeks before being grafted. The homogenous grafts were placed on the left ilium and the autogenous grafts on the right ilium. The grafts were removed with a ¾ inch (1.9 cm.) tubular saw fashioned from a cork drill so that the bed and the graft were always of the same shape and size. The grafts were held in place by means of tantalum wire, which was threaded through drill holes in the graft and in the ilium and twisted until the graft was held firmly in place. The wounds were closed with interrupted cotton sutures. There were no casualties and in only one wound was there a superficial infection. The rabbits were killed at three and six week intervals, and the grafted areas were studied grossly, roentgenographically and microscopically. Thirty-two bone transplantations were made by twenty-eight operations on 19 animals. Twenty-nine of the grafted areas were considered suitable for analysis. Results are expressed in terms of a "healing index" as shown in table 1.

TABLE 1.—*Order of Healing of Grafts*

	Healing Index*	
1. Autogenous fresh	13/5	2.6+
Autogenous frozen 7 days	8/3	2.66†
2. Autogenous frozen 14 days	5/3	1.66§
Homogenous fresh	6/4	1.5
Autogenous frozen 28-84 days	4/3	1.33
3. Homogenous frozen 7-84 days	7½/7	1.07¶
Autogenous boiled.	2/2	1.0
4. Homogenous frozen boiled	1/2	0.5

*This is a figure derived from a numerator representing a summation of grading figures and a denominator denoting the number of transplants involved. In grading the individual case 4 equals excellent (pronounced restitution toward normal architecture), 3 equals excellent to good, 2 equals good (graft fused to bed of host, metaplastic new bone formation along at least one side of the cortex and also extending up into medulla for a short distance), 1 equals fair (graft only fused to bed of host, with or without callus on one side of cortex) and 0 equals nonunion (or excessive peripheral resorption of bone and little formation of new bone).

+Figure 1.
†Figure 2.
§Figure 3.
¶Figures 4 and 5.

Frozen bone grafts regularly became attached to suitably prepared beds of host bone and were slowly and at least partially replaced by new bone formed by the host through metaplasia or creeping substitution. Fresh autogenous bone and autogenous bone preserved in frozen condition for one week and even for two weeks were more quickly and completely reconstituted into bone approaching normal architecture than frozen homogenous bone, but there was little difference in favor of autogenous bone when preservation in the frozen state was prolonged beyond twenty-eight days. This seems to indicate that the autogenous bone cells usefully survived freezing at minus 24 C for one week and that some cells survived for two weeks. The possible effect of slow denaturization of autogenous protein is also to be considered.

Epiphysial cartilage attached to bone which had been frozen for two weeks was necrotic when examined three or more weeks after implantation and was noted to interfere locally with formation of new bone. Boiled autogenous bone grafts were inferior to frozen bone grafts, the medulla being poorly revascularized and showing no formation of new bone. The importance of reestablishing circulation in bone transplants is indicated by the inferior formation of new bone in several animals in which grafts had become augulated thereby preventing revascularization directly from medulla of the host.

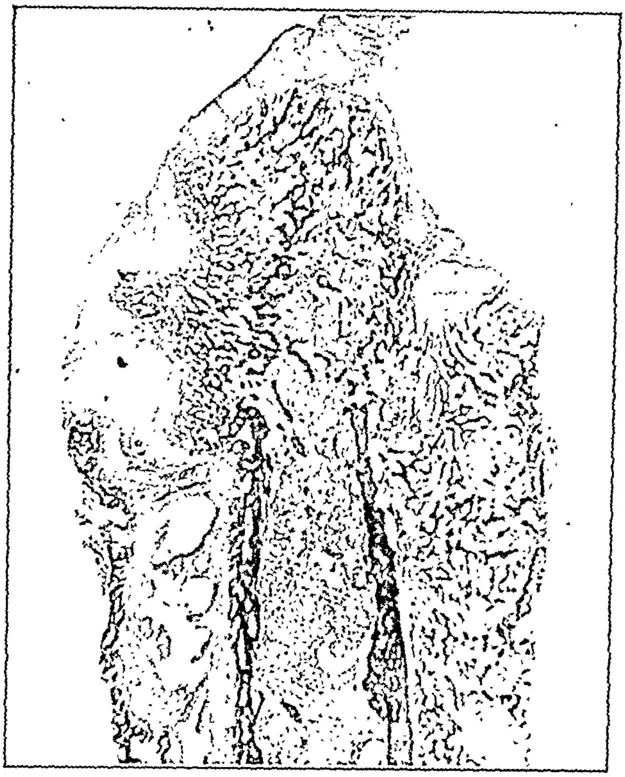

Figure 2.--Autogenous graft, frozen at minus 25 C. for 7 days prior to implantation, 21 days in animal 107. Result was graded as "excellent."

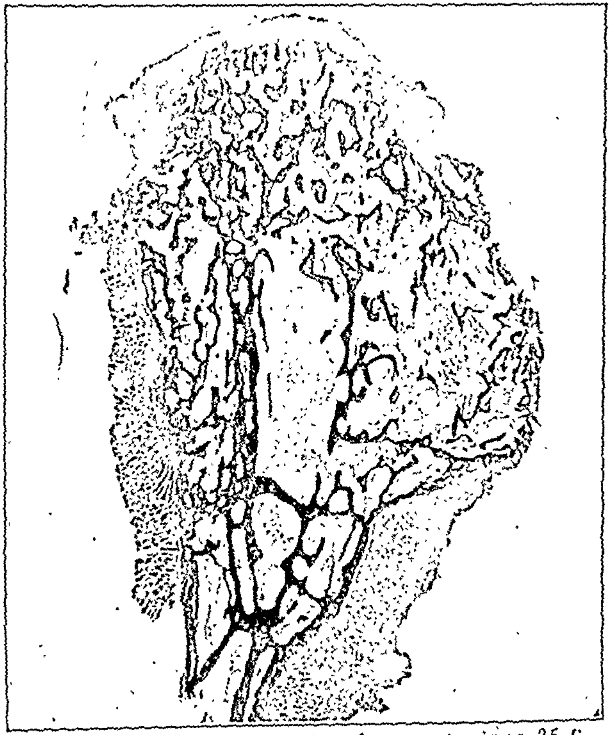

Figure 3.--Autogenous graft, frozen at minus 25 C. for 14 days prior to implantation, 42 days in animal 108. Result was graded as "excellent."

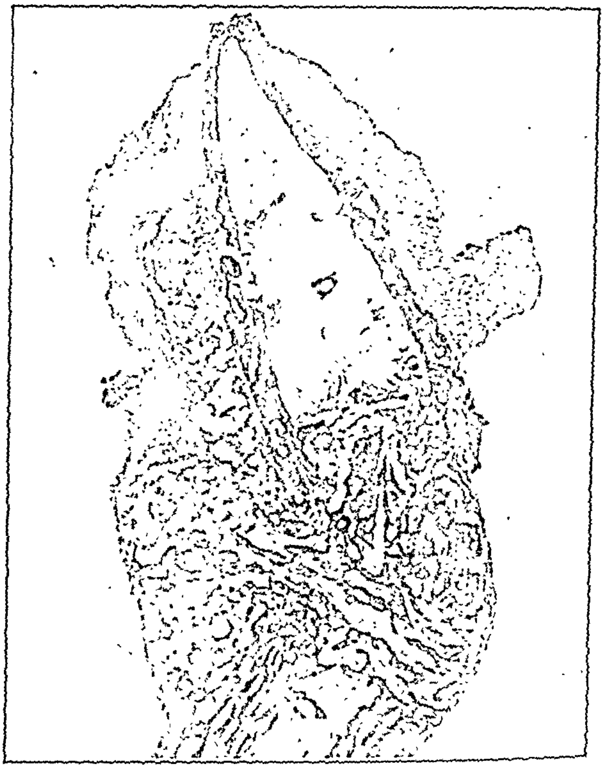

Figure 4.--Homogenous graft, frozen at minus 25 C. for 14 days prior to implantation, 42 days in animal 108. Result was graded as "fair to good." There was poor revascularization of marrow in the graft.

The inclusion of boiled autogenous bone as a part of this experiment is not without merit in establishment of a base line. Accidents in operating rooms have occasionally resulted in enforced use of such material, and with clinical success. Numerous experiments with animals recorded in the literature[6] have shown that boiled grafts can be made to succeed though they do so rather slowly as compared with fresh autogenous grafts. The healing index of our homogenous frozen bone was in the same range as that of autogenous boiled bone, though slightly higher. More exact establishment of this point with a considerable number of dogs is desirable.

CLINICAL STUDIES

Having proved that this method of preserving bone was successful in animals, we felt that it was safe to attempt it in man. Thus all available clean fresh bone was placed in

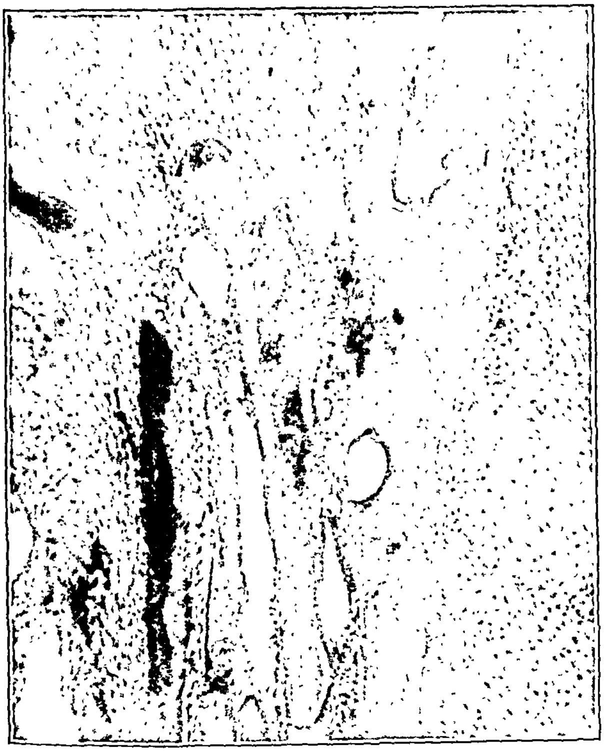

Figure 5.--Homogenous graft, frozen at minus 25 C. for 84 days prior to implantation, 21 days in animal 103. Result graded as "fair to good" at low power. However, this high power view shows formation of abundant cartilage callus and metaplastic osteoid tissue adjacent to the necrotic eroded bone of the graft.

bottles as illustrated (fig. 6) and frozen at minus 25 C. Because infection developed in 1 case, the bone is now kept for two weeks before using, while the donor remains under observation for evidence of developing wound infection. In a previous paper by one of us (L.F.B.)[7] the additional precautions of a negative serologic reaction for syphilis and no history of recent jaundice, malaria or infection were outlined. All the necessary data concerning the donor and the specimen are filed in a card index (table 2).

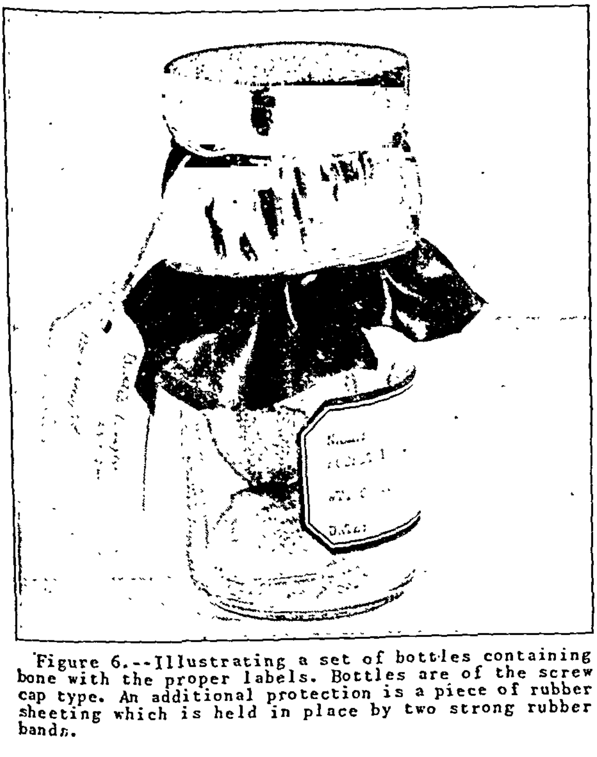

Figure 6.--Illustrating a set of bottles containing bone with the proper labels. Bottles are of the screw cap type. An additional protection is a piece of rubber sheeting which is held in place by two strong rubber bands.

Date Used:	

*The weight of the bone is recorded chiefly to give an index as to the amount of bone present in the bottles.

The donor bone is obtained from any clean source, the largest and best supplies coming from the tibia and the ilium. By the exercise of diligence, considerable bone may be accumulated from many sources. In operative procedures in which part of the ilium is sacrificed and in many others in which the tibia is exposed for autogenous onlay grafts, extra bone may be placed in the bottles for the bank. Bone used to date has been from living sources. Larger quantities of bone will be obtained eventually from other clean sources in instances of death by trauma, still-born infants, and clean amputations. Autogenous bone may likewise be stored for use in secondary operations.

CLINICAL RESULTS

At the present time homogenous bone has been used in 126 operations in 104 patients. Of these, 24 operations were by direct transfer; refrigeration at plus 2 to plus 5 C. was used in 37 instances, and the bone was stored in deep freezer for 43 operations.

Donor bone has been used in any case in which extra bone was required, the chief uses being spinal fusions for scoliosis and diseases of the lower part of the back; filling bone cysts with chips; fusions of various joints and rare diseases such as osteogenesis imperfecta. The addition of homogeneous bone after a Hibbs type of spinal fusion has proved to be most helpful, judging from the results studied in 91 patients.

The evidence accumulated to date shows that donor bone is of definite value in bone-grafting operations. The time required for operations is lessened and the necessity of secondary operations in many instances is eliminated.

---

[7] Bush, L. F.: The Use of Homogenous Bone-A Preliminary Report on the Bone Bank, J. Bone & Joint Surg., to be published.

Biopsy studies have been possible where homogenous bone was used in multistage spinal fusions for scoliosis. Microscopic examination of the tissues seemed at first discouraging, because the bone spicules of the graft were dead and disintegrating and exhibited a relatively small amount of marginal metaplastic new bone, but grossly there appeared to be excellent formation of new bone. The donor bone furnished a framework for the formation of new bone by substitution and by furnishing the necessary calcium for this new bone.

TABLE 3.--Summary of Data on 126 Operations

Total patients -	104
Total operations -	126
Operations:	
Spinal fusions	
(a) Scoliosis	44
(b) Lumbosacral	14
(c) Repair pseudarthrosis	18
(d) Spinal fracture	4
(e) Adolescent kyphoses	3
(f) Tuberculosis of spine	8
Bone cysts, filling with chips	6
Ununited fractures in osteogenesis imperfecta	4
Fusion, wrist	2
Onlay graft for congenital pseudarthrosis of tibia	1
Infections--2	

COMPLICATIONS

Complications have been few. In the 104 cases in which donor bone was used, there were 4 complications, as follows: infections, 2; fracture of onlay grafts, 1, and failure of soft tissue coverage, 1.

SUMMARY

Experimental bone-grafting studies on rabbits showed: *(a)* Freezing at low temperature is a safe method of prolonged preservation of bone for grafting purposes. *(b)* Bone grafts three to six weeks after implantation were successful in the following descending order efficiency: (1) autogenous fresh, autogenous frozen 7 days, (2) autogenous frozen 14 days, homogenous fresh, autogenous frozen 28 to 84 days. (3) homogenous frozen 7 to 84 days, autogenous boiled. The implications of these results cannot be extended from rabbit to man with any certainty, and the experiment should be repeated with a large number of other animals. *(c)* Epiphysial cartilage attached to bone which had been frozen for two or more weeks became histologically necrotic after implantation and interfered locally with osteogenesis. *(d)* Circulation played a most significant role in the success of grafting experiments. Proper seating of the graft was important.

Human bone is preserved apparently indefinitely in a freezer at minus 20 to 30 C.

Donor bone has been used in 126 operations on man with but 4 complications.

The successful results obtained prove the value of donor bone which the bone bank makes available in a constant supply.

ABSTRACT OF DISCUSSION

Dr. J. R. COBB, New York: The development of the bone bank is one of the most important advances in orthopedic surgery. Our experiences at the Hospital for Special Surgery support this work of Dr. Bush and Dr. Garber. During the past twelve years we have studied the healing of the patient's own bone in the two stage fusion operations for scoliosis. Some of the patient's tibial bone chips used for the first stage spinal fusion were removed at the second stage (at varying intervals of two weeks to several months) and studied microscopically. These specimens all show dead and revascularizing bone. Whether we use the patient's own fresh bone or refrigerated bone from the same patient or from other donors, the results seem to be essentially the same both clinically and on microscopic examination. We have been using a bank for refrigerated bone since April 1946. Dr. Philip Wilson reported our results at the meeting of the American Surgical Association on March 27, 1947. At that time we had used refrigerated bone from 38 donors in 28 operations on 23 recipients. As an indication of our satisfaction with the results to date we have already increased these figures to 51 donors and 41 recipients. We have had no infections and our only complications have been: 1 instance of pseudarthrosis in a spinal fusion for transection of the cord with anesthesia when adequate immobilization in plaster was impossible because of pressure sores; 1 extrusion of chips following an attempt to fuse and repair a spinal fluid leak, and 1 soft tissue slough which healed in a few days. While we usually wait 72 to 96 hours for a negative culture report before using the bone, we have used it the same day and as late as 89 days, the average being 42 days. We believe that if it is kept constantly at a sufficiently low temperature without contamination and properly sealed bone can be kept indefinitely, but we have so many needs for extra bone that it does not stay in the bank long. In most of our cases we have given the recipient 50,000 units of penicillin every three hours for the first few days or until the temperature is normal. In 1 case of severe paralytic scoliosis we used bone from 9 donors in a three stage fusion, with excellent results. All of us who have used refrigerated bone have been impressed by the simplicity, safety and usefulness of the bone bank. However, while a bone bank on a small scale is desirable in every hospital with an active bone and joint service, there are great potentialities for further development of the bone bank. As

Dr. Wilson has pointed out, we need an organization on a much larger scale, of a community bone bank to supply the needs of surgeons for bone transplants of every size and description. This work by Dr. Bush and Dr. Garber is an important step toward that goal.

DR. FRANK E. STINCHFIELD, New York: The purpose of a bone bank is not to replace the use of autogenous bone but to serve as an adjunct in grafting when it is impossible to obtain enough bone from autogenous sources. There is definite proof, both experimentally and clinically, that autogenous bone is better than homogenous bone. It is almost impossible to do a purely homogenous bone graft since it will always be combined with autogenous bone which has been chipped at the site of the graft. The most important requisites in bone grafting are a careful preparation of the host bed and an adequate blood supply to the involved area. The problem of histopathology of bone repair is incompletely understood, but it would seem that the bone graft supplies local calcium and acts as a trellis on which the new bone is formed. It is doubtful that many—or any—of the cortical cells survive, although I believe that some of the autogenous cancellous bone cells live. It is difficult to see under the microscope the relative viability of living bone cells in the early states of repair, and the death of cells can be noted only when the lacunas are absolutely empty. The paper fairly well refutes the theory that there is incompatability of individuals in receiving homogenous bones and that the poor results are due to blood or tissue incompatability. Brooks proved that autogenous bone grafts in young dogs grow better than in older ones but that homogenous bone transplants have no relationship to the age of either donor or recipient. It is my impression from reviewing bone grafts in human beings that the best results are obtained when bone is transplanted from adult to adult rather than from youth to adult as one might expect. The problem of bone preservation is one of prime importance at the present time. The National Research Council, the Medical Department of the Veterans Administration and the United States Army are all interested in determining how to store bone at low temperatures so that it may be used at a later date. Much work has been done on the clinical application of homogenous bone from a procedural point of view, but little has been done on the basic problem of determining the physiologic and histologic processes which occur when bank bone is used. Another interesting problem would be to determine the rapidity with which the bone should be frozen and the rate at which it should be thawed out. These two factors alone might make a great deal of difference. Too, it might be advisable to take cultures of the specimens at the time of surgery and also immediately before implantation of the bone graft in the host. I am much interested in knowing how long the authors feel that bone can be stored and still used advantageously. In time of war this may be an important factor. The unfortunate publicity which has accompanied the establishment of bone banks throughout the country is disturbing. The obtaining, preservation and use of bank bone is not as simple as it sounds, and such publicity is apt to cause some disastrous results. It should be borne in mind that a bone bank is different from a blood bank, as in blood transfusions there are no regenerative powers attendant whereas in bone transplants the host must do more than just tolerate the alien tissue. My feeling is that we should proceed cautiously and not use bank bone indiscriminately until we have more definite data and a longer follow-up.

DR. D. B. PHEMISTER, Chicago: I think that it should be more definitely established by histologic studies both in experimental animals and in man whether or not the homogenous banked bone transplants form new bone which persists and takes part in the union and bony transformation of the graft. It has been reported by Marine, Lexer, Axhausen and others that in homologous transplants--some in man and others in experimental mammals--the surface cells may survive and multiply but that after ten or twelve days a foreign protein reaction against the graft develops in the host and the new tissue, which it has formed, dies. Replacement of the dead graft is then brought about by proliferation and invasion of the tissue of the host. The evidence presented here appears to be conclusive that banked homogenous bone functions satisfactorily when used as a transplant. The question to be settled is whether it acts as well as autogenous bone or only in a capacity comparable to that of boiled bone, which has also proved satisfactory in certain types of cases.

DR. LEONARD F. BUSH, Danville, Pa.: There are several points that we could have clarified in this paper had we had more time. Many of these were previously brought out in the paper presented in New York in February, 1947. It was not the purpose, or not our point, to make you think that homogenous bone is a panacea. Certainly, it is not as good as autogenous bone but it has a place, and when autogenous bone is not available, this is the second best substance. We showed definitely in the first paper that the homogenous bone did not grow. We had twelve biopsies, all of which showed dead spicules of bone with pronounced metaplasia of connective tissue cells and new bone formation, but we felt that this is somewhat in direct contrast to the autogenous grafts which some men believe grow. Certainly, some of the cells may grow, but how many and how long they grow is a subject for considerable discussion. How long can a bone be stored? I do not know. We tried to keep a constant supply available and rotate the stock and use-up the old bone first, and it seems we have a hard time getting any stock, or any deposits in the bank. But we have kept it safely for three or four months. I appreciate Dr. Stinchfield's caution to orthopedic surgeons in general, or general surgeons who are contemplating taking up the use of the bone bank. It is a very apropos remark, and I would say that we should be very careful in doing work in which homogenous bone is used, and proceed carefully. In other words, "Don't rush the bank."

ANALGESIC EFFECTS IN HUMAN SUBJECTS OF MORPHINE, MEPERIDINE AND METHADON

EUNICE M. CHRISTENSEN, M.D. and E. G. GROSS, M.D.

Iowa City, Iowa

Certain disadvantages of previously known potent analgesics have led investigators to search for new drugs which possess good analgesic properties but lack undesirable side effects. Following World War II knowledge of a new group of compounds prepared by German chemists was disclosed in a report by the United States Department of Commerce.[1] Scott and Chen [2] have recently reported pharmacologic studies of members of this series. They found one of these compounds, methadon (6-dimethylamino-4, 4-diphenyl-3-heptanone), to be outstanding. The following study deals with a comparison of the analgesic properties of this drug[3] with those of morphine and meperidine hydrochloride ("demerol hydrochloride").

The side effects and analgesic properties of methadon in combination with atropine and scopolamine were studied to determine the possible value of methadon as a premedication agent for anesthesia. Because these two agents altered the threshold effect of methadon, similar combinations were used with morphine and meperidine.

Slaughter and Munsell [4] and Floodmark and Wrammer [5] have reported that neostigmine enhanced the analgesic action of the opiates. The analgesic effects of neostigmine alone and in combination with each of the analgesic drugs were tested. Clinical studies were undertaken to evaluate methadon as a preoperative and postoperative analgesic agent.

PROCEDURE

The analgesic measurements were determined by the Wolff, Hardy, Goodell method,[6] a machine being used which was built by the Experimental Engineering Laboratories. Eleven human volunteer subjects (5 medical students and 6 staff members) were tested. They remained quietly seated during the exposure but were allowed to read or study between the readings. All subjects rested at least ten minutes before normal threshold was determined. The end point used was a sudden "welling up" of pain at the end of the three second exposure. Room temperature was maintained at approximately 24 C. Drafts and excessive humidity were avoided. The finding that normal thresholds were remarkably constant in all subjects and remained so throughout the study is in agreement with the report of Wolff, Hardy and Goodell.[6] Exposures to the light beam were made on the blackened forehead at twenty minute intervals after subcutaneous and at ten minute intervals after intravenous administration of the drugs. The subjects were not informed of the identities of the drugs they received. After some experience, however, they were able to identify each compound or combination of drugs by the side effects. At least one week elapsed between the administration of two doses of the same drug to any subject. All alterations in pain threshold are presented as percentage change from the normal threshold.

RESULTS

Laboratory Results.—Chart 1 shows a representative curve of the effect on the pain threshold of three doses of methadon administered subcutaneously to the same subject. Chart 2 demonstrates a typical set of curves of the variation in response of 7 different subjects to a 2.5 mg. subcutaneous dose of methadon. It was felt that an average curve could represent the analgesic activity of

each drug. Average threshold curves at three dose levels are presented in charts 3, 4 and 5 for each of the drugs when given subcutaneously. When the three drugs were administered intravenously a somewhat greater variation in response of the different subjects was noted. To conserve space the remaining figures will show only peak threshold rises and total duration of analgesia. The results obtained following subcutaneous and intravenous injections of all three drugs are shown in chart 6. The duration of analgesia of all three drugs following subcutaneous injection is much longer than that following an intravenous dose. Peaks of threshold rise were usually reached in eighty to ninety minutes when the agents were given subcutaneously and in fifteen to twenty minutes after an intravenous injection. These time intervals agree closely with those of other authors. Methadon appears to be approximately three times as potent as morphine and many times more potent than meperidine when given subcutaneously. This finding agrees with that of Scott and Chen.[2ac] It will be noted that the peak threshold intensity of methadon is less and of meperidine greater when given intravenously as compared to a similar dose subcutaneously. The peak intensity of morphine was about the same for either route of administration. Observations were frequently terminated when pain thresholds had returned to within a few per cent of normal. In all cases in which complete duration was followed the pain thresholds became subnormal for a period. This observation was also made by Pfeiffer and Seevers.[7]

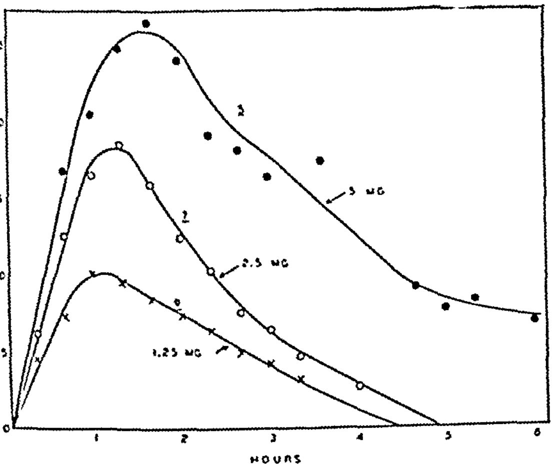

Chart 3.—Average effects on the pain threshold of varying doses of methadon injected subcutaneously. Underlined figures indicate the numbers of subjects used in obtaining the curves.

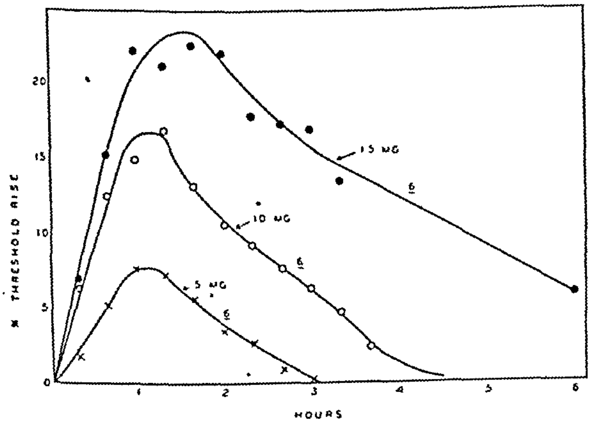

Chart 4.—Average effects on the pain threshold of varying doses of morphine sulfate injected subcutaneously. Underlined figures indicate the numbers of subjects used in obtaining the curves.

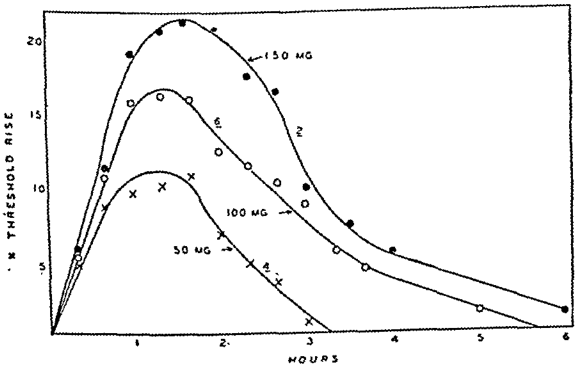

Chart 5.—Average effects on the pain threshold of varying doses of meperidine injected subcutaneously. Underlined figures indicate the numbers of subjects used in obtaining the curves.

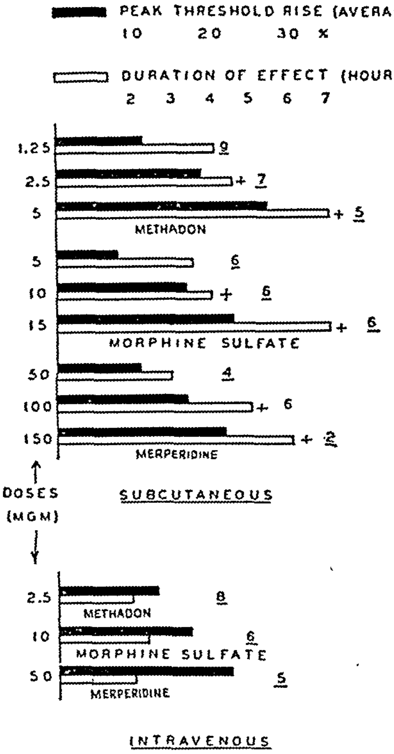

Chart 6.—Average effects on the peak threshold and duration of analgesia are represented for varying doses given subcutaneously and one dose level given intravenously of each analgesic studied.

In a few subjects, repeated doses of 1.25 mg. of methadon were administered. The second and third doses were repeated when the threshold was at or near normal. These repeated doses gave threshold rises about equal to the original rise.

Oral doses produced decided variations in both intensity and duration, and no satisfactory comparison could be made. These variations are probably due to different rates of absorption.

Methadon produced only slight sedation when given subcutaneously. On intravenous injections there was rather pronounced sedation for about the first ten minutes. In all instances the degree of sedation was less

Seevers, M. H., and Pfeiffer, C. C.: Study of Analgesia, Subjective Depression and Euphoria Produced by Morphine, Dilaudid and Codeine in Normal Human Subject, J. Pharmacol. & Exper. Therap. 56: 166-187 (Feb.) 1936.

than that produced by either morphine or meperidine. Nausea and vomiting were not experienced by any of the subjects. No euphoria was reported by any of the subjects.

Atropine or scopolamine in a 0.3 mg. dose was injected simultaneously with each analgesic agent, because this was the usual minimum preoperative dose used clinically. The results following the subcutaneous administration of the analgesic agents in combination with 0.3 mg. of either atropine or scopolamine are shown in chart 7. It will be noted that in all instances when the combination was given subcutaneously the duration of analgesia was shortened. The peak threshold rises were less when morphine and methadon were combined with atropine or scopolamine but were not greatly altered when the drugs were used with meperidine. When atropine was given subcutaneously to two subjects one-half hour before methadon the *intensity* and duration of analgesia still remained less than when methadon was given alone. When a 0.3 mg. dose of atropine was injected intravenously forty minutes after a subcutaneous dose of methadon the intensity of the analgesia immediately began to decrease and total duration was greatly shortened from the normal effect of a similar subcutaneous dose of methadon alone (chart 8).

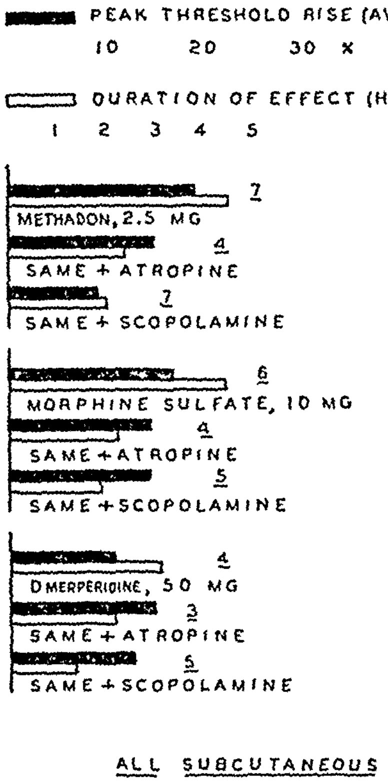

Chart 7.—Average effects of 0.3 mg. of atropine sulfate or scopolamine bromide on the peak threshold and duration of analgesia produced by the subcutaneous injection of the analgesic compounds.

When the three analgesic drugs were administered intravenously with atropine or scopolamine, the only consistent change was a shortening of duration effect of methadon (chart 9).

Undesirable side effects of morphine and meperidine such as nausea and vomiting were absent when either atropine or scopolamine was given with these two agents. The sedative action of scopolamine with these drugs appeared to be additive. The subjects who received methadon in combination with atropine or scopolamine noted only the subjective symptoms of atropine or scopolamine.

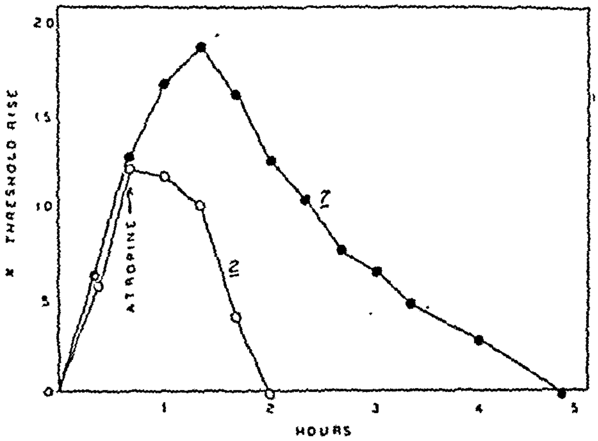

Chart 8.—Average effects on the pain threshold of 0.3 mg. atropine sulfate given intravenously forty minutes after the subcutaneous injection of 2.5 mg. of methadon.

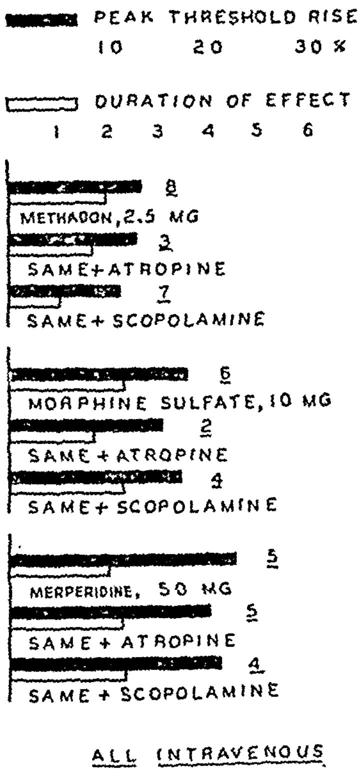

Chart 9.—Average effects of 0.3 mg. of atropine sulfate or scopolamine bromide on the peak threshold and duration of *analgesia* produced by the intravenous injection of the analgesic compounds.

Atropine or scopolamine in 0.3 mg. subcutaneous or intravenous doses did not alter the pain threshold of three subjects.

Chart 10 represents the increased threshold effect when 0.5 mg. neostigmine was injected either subcutaneously or intravenously with each analgesic drug and when administered alone. The combinations with neostigmine produced greater sedation than did the three analgesics alone. These findings confirm the results of Slaughter and Munsell with the opiates.[4] Contrary to the findings of Slaughter and Munsell [4] but confirming the results of Floodmark and Wrammer[5] it was found that neostigmine produced considerable rise in pain threshold when it was administered alone.

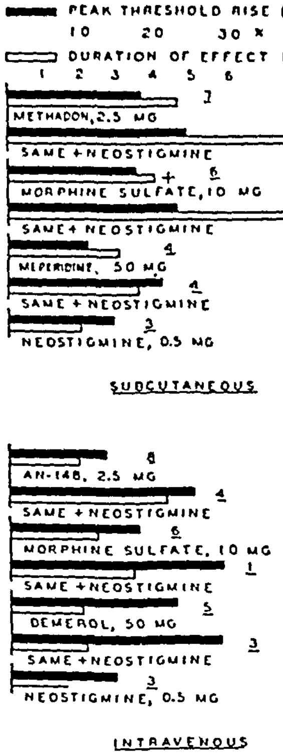

Chart 10.—Average effects of 0.5 mg. of neostigmine sulfate on the peak threshold and duration of analgesia produced by the analgesic compounds.

Clinical Results.—Sixty-nine patients, 37 female and 32 male, received methadon as a preanesthetic agent. Their ages ranged from 14 to 77 years. All received 5 mg. of methadon combined with either 0.3 or 0.4 mg. of scopolamine. The majority of the patients received the combination intravenously. In addition 0.06 to 0.2 Gm. of sodium pentobarbital was given to all patients before spinal, regional or local anesthesia.

The anesthetic agents are shown in table 1.

TABLE 1.—*Anesthetic Agent*

Field block	1

Administration of methadon, 5 mg., was repeated on an average of once during each operation of over one and a half hours when the anesthetic agent was nitrous oxide.

The majority of the patients who received nitrous oxide had abdominal surgical treatment. As all patients in this group were intubated under intravenous barbiturate and curare, no evaluation of methadon during the induction period was attempted. However, these patients did require larger amounts of "pentothal sodium" for sedation and curare for relaxation than did the control patients premedicated with morphine and scopolamine.

Most of the subjects who received cyclopropane had no prolongation of the induction period. They had as smooth an anesthetic course and as good relaxation as did those premedicated with morphine. All persons premedicated with methadon except those who received a large amount of "pentothal sodium" during surgical treatment were awake and alert when they left the operating room. Most of the subjects premedicated with methadon and scopolamine who had spinal or local anesthesia were apprehensive throughout the operation. It appears that this agent does not produce sufficient sedation for this type of anesthesia. This observation agrees with that of Scott, Livingstone and others.[8]

Apprehension	3
Induction time prolonged	3
Respiratory depression	4
Blood pressure rise	1

Table 3 shows the postoperative course. Except for 8 patients who received morphine routinely postoperatively, no patient was given an analgesic until he complained of pain. Forty-four of the remaining 61 persons experienced no pain the first twenty-four hours. Four subjects received only partial relief from pain or were classed as dissatisfied. These received 5 mg. every four hours. One of these was an alcoholic addict, and 1 was a known addict who demanded morphine after two doses of methadon because she received "no kick from the shot." One highly emotional person enjoyed the euphoria from opiates and demanded dihydromorphinone hydrochloride: The other patient was only partially relieved by two doses of methadon intramuscularly after a vaginal plastic operation.

Superior vena cava cut during operation; cerebral anoxia	1

Eleven additional patients received methadon either orally or intramuscularly for pain from various causes including cancer, tic douloureux, peripheral vascular disease pain, migraine, other headaches and arthritis. Doses varied from 2.5 to 5 mg. every three to four hours. Six obtained complete relief from pain; 1, an arthritic received no relief with one dose of 2.5 mg. and refused to repeat it. Two had previously received morphine in 10 and 15 mg. doses every four hours from one to two months with complete relief from pain. Methadon was abruptly substituted. Both complained that the "shots had no kick." After twenty-four hours both became satisfied and received complete relief from pain from 5 mg. intramuscularly four to five times a day. Two patients with cancer who were only partially relieved of pain by large doses of morphine and meperidine were also not completely relieved by 5 to 10 mg. of methadon. A combination of 5 mg. methadon and 0.5 mg. neostigmine afforded 1 of these patients longer relief from pain. The 1 person who was nauseated from 2.5 mg. methadon was also nauseated after an injection of isotonic solution of sodium chloride. Euphoria was noted by 1 subject.

---

[8] Scott, W. W.; Livingstone, H. M.; Jacoby, J. J., and Broberg, G. G.: Early Clinical Experience with Dolophine (No. 10820), Anesth. & Analg **26:** 18-20 (Jan.-Feb.) 1947.

The best analgesia was obtained in cases of postoperative pain. This agrees with the conclusion of Scott, Chen and Kohlstaedt[2c] and Scott, Livingstone and others.[8]

COMMENT

The fact that intensity and duration of the analgesic action of methadon were markedly shortened by atropine or scopolamine helps explain why methadon was frequently an unsatisfactory premedication agent. This combination of drugs lacked both analgesic and satisfactory sedative properties.

Small doses of methadon afforded good analgesia clinically. Methadon seemed most useful for postoperative pain and for relief of pain from many other causes. Combined with neostigmine it should afford even greater relief for patients who have severe pain.

SUMMARY

Methadon is an analgesic agent three times as potent as morphine and many times more potent than meperidine. It lacks sedative properties. Undesirable side effects are minimal. It may be administered intravenously for analgesia of rapid onset and short duration or subcutaneously for slower onset and longer analgesic action.

Therapeutic subcutaneous doses of atropine or scopolamine decreased both intensity and duration of the analgesic effects of methadon and morphine as measured by determination of pain threshold. The duration but not the intensity of the analgesic action of meperidine was shortened.

When the analgesic drugs were administered intravenously with atropine or scopolamine, the only consistent change was a shortening of duration effect of methadon.

Atropine and scopolamine produced no analgesia as measured by determinations of pain threshold.
